All are agreed that the symptoms are at first inconsiderable, and where the enlargement of the glands is but slight are ill-defined. As the glandular tumours are most frequently (the tubercular) accompanied with tubercular deposition in the lungs, it is the latter which usually attracts the attention of the physician, and produces such manifest symptoms that the glandular disease is overlooked. It is not until the latter have attained such a size that they exercise considerable pressure on the air-passages, the large vessels, the nervi vagi, or the other organs in the thoracic cavity, that the disease assumes a peculiar type, and a diagnosis becomes possible. Cough is, however, one of the first symptoms, though it is not until the disease is more advanced that it acquires a special character. It is usually dry and irritating, as it were spasmodic, comes on in fits, and has sometimes a hollow or rough sound. The expectoration is, at the same time, nil, or extremely scanty, and of a catarrhal nature. Our patient was, it is true, troubled with a dry, irritating cough, but we never observed anything peculiar in it, except during the asthmatic paroxysms. The pains in the chest are ordinary, but vary. Sometimes inconsiderable, as merely a feeling of pressure; they may, in others, be extremely violent. Our patient

seldom complained, so far as the chest was concerned, of anything but dyspnoea, but this scarcely ever left her.

The voice most frequently exhibits nothing unusual, with the exception of a certain weakness, which may, however, sometimes pass into complete aphonia from pressure of the tumours on the recurrent nerve (*Aphonia paralytica*)? In our case the voice was always rather rough, and to speak loudly and distinctly invariably required evident effort. Yet the laryngoscope never revealed any defect of mobility in the vocal apparatus.

In this, as in other thoracic affections, the signs afforded by physical examination of the chest are the most important. It is generally stated that the *respiration* exhibits nothing abnormal except during the asthmatic attacks, but in this case it was evident that it was always attended with a certain amount of difficulty, and when forced it produced a peculiar tracheal sound. As is observed in the history of the case, the breathing was, moreover, often audible at a distance, and frequently it was accompanied with a sound suggestive of the existence of constriction of the larynx. But this was most intense during the violent attacks of dyspnoea, which more than once attained such a height as apparently to threaten suffocation. Such asthmatic attacks are not unusual in this disease; in this instance they were the first symptom which directed attention to the affection of the chest. During them, inspiration and expiration may assume such a character that we might be tempted to suspect the existence of some more severe laryngeal affection, a mistake which Fonsagrives acknowledges he was once very near committing, as he believed that in such a case he had to do with *oedema glottidis*.

In children very important information may often be obtained from percussion, when it is possible to establish the existence of a circumscribed dullness, indicating the situation, and perhaps even the size of the tumour. In adults it is a rare exception that the swelling attains such a size that any alteration of the sound on percussion ensues, but in the very circumstance that this is normal, while the other symptoms indicate a severe affection, lies something very peculiar, which deserves all attention.

Fonsagrives lays great weight on accurate palpation, by which we shall often be able to establish the existence of an increase of the thoracic vibrations, or of *frottement* in a limited space, in some of the sub-clavicular regions. As to increase of the thoracic vibrations, F. thinks that probably the strong, purring, or sonorous râles, which are often met with in such cases, may be perceived also with the hand, for there can be no question of any increase of the vocal vibrations in the chest unless the tumours have attained such a size as to compress and condense a great portion of the lung, which is extremely rarely the case. How *frottement* can be caused by such tumours it is difficult, nay impossible, to see. It is true that Laennec has put forward the assertion that nodules of a tubercular or other nature, if of a certain size and projecting above the surface of the lung, may give rise to friction sounds, but this also has been called in question by more recent investigators. I cannot say whether Laennec's authority has had any part in the quoting of this symptom by Fonsagrives; by no other author have I found it mentioned.

Auscultation affords in general the most reliable signs, although precisely with respect to these, observers seem to be least agreed. That, as a result of any more considerable constriction of the larger bronchial tubes, aeration shall be diminished in the part of the lung to which the constricted air-tube leads, and that the vesicular murmur shall there in the same measure lose in strength, seems to me to be, *a priori*, quite clear, and is also fully confirmed by experience. Others, too, usually state that such is the case; but, nevertheless, Fonsagrives thinks, with respect to bronchial tumours, that "weakness in the respiratory murmur is rather theoretically deduced from the nature of the disease than established by experience." But Andral had before directed attention to this change in the respiratory murmur, and had based on this very point his diagnosis in a similar case (compressing glandular tumour in the thorax).

Fonsagrives, on the other hand, describes, as especially characteristic, great sonorous, stertorous (*à timbre ronflant*), râles, constantly fixed in a certain part. In our case, too, a *strong tracheal-like sound* was observed over the anterior part of the lungs, which often completely masked the other auscultatory phenomena. Other writers have not, however, in similar cases, observed any such sounds, and Duchek (*Handbuch der speciellen Pathologie und Therapie* i, p. 424) considers that a prolonged râle on inspiration or expiration is by no means met with in all cases. However this may be, it is certain that this peculiar, if we will, stertorous sound, from the very commencement in this case fixed my attention and contributed to the establishment of the diagnosis.

In conclusion I will add that these tumours may sometimes produce, in consequence of pressure on the large venous trunks in the thorax and on the œsophagus, very important symptoms, which greatly facilitate the diagnosis.

## Reviews.

GLEET: its Pathology and Treatment. With a Memorial on the Treatment of Stricture of the Urethra by Subcutaneous Division. By HENRY DICK, B.A., M.D., Surgeon to the National Orthopædic Hospital. Second Edition. Pp. 113. London: Hardwicke. 1866.

THE treatise on Gleet is the result of many years' observation, and Dr. Dick's object in publishing it is to elucidate some essential points which he considers to be often neglected. The Memorial on the Treatment of Stricture of the Urethra by Subcutaneous Division was read before the Medico-Chirurgical Society, and the peculiar method devised by the author is described; but Dr. Dick wishes it to be understood that he does not propose the subcutaneous division in all cases of stricture, but only in exceptional instances.

A PRACTICAL TREATISE ON FRACTURES AND DISLOCATIONS. By FRANK HASTINGS HAMILTON, A.B., A.M., M.D., Professor of the Principles of Surgery, Military Surgery and Hygiene, and of Fractures and Dislocations in Bellevue Hospital Medical College, New York, &c. Third Edition, revised and improved, pp. 777. Philadelphia: H. C. Lea, 1866.

THIS excellent treatise has passed so rapidly through two editions that a third has been imperatively demanded, and in its preparation Dr. Hamilton has been assisted by Dr. John Winslow, of New York, to whose zealous co-operation he pays an appropriate tribute. He has also added a considerable number of observations from his own private practice, and from that of the Bellevue and Charity Hospitals in New York, and the chapter on gunshot injuries has been enlarged by the addition of a few statistics obtained from the published records of the United States and Confederate armies. These sources must have supplied an enormous mass of contributions to the surgery of Fractures and of other surgical injuries, but, as is usual in great campaigns, the majority of surgeons are too much engaged in the practical duties imposed upon them to have much leisure for writing the results of their experience. Dr. Hamilton's book is illustrated by no less than two hundred and ninety-four woodcuts, illustrating the anatomical characters of the fractures and dislocations described, and also the different methods of treating these injuries, and the various mechanical appliances employed in their management. The treatise is very creditable to the character of American Surgery.

NOTES ON HEALTH IN CALCUTTA AND BRITISH EMIGRANT SHIPS, including Ventilation, Diet, and Disease. By W. H. PEARSE, M.D. Edin., Government Emigration Service. Pp. 160. London: Churchill and Sons. 1866.

THIS is a thoroughly practical little work on a very important subject in which the author has had a very considerable experience. It is illustrated by tables, which must have been collected with great labour, relating to various medical statistics of life and disease on board ship, together with many useful suggestions for the preservation of the one and the prevention of the other.

**CHOLERA: its Seat, Nature, and Treatment.** By CHARLES SHRIMPTON, M.D., Chevalier de la Légion d'Honneur, &c. Pp. 109. London: Churchill and Sons. 1866.

**A TREATISE ON THE ORIGIN, NATURE, PREVENTION, AND TREATMENT OF ASIATIC CHOLERA.** By JOHN C. PETERS, M.D. Pp. 162. New York: D. van Nostrand. 1866.

**ON MALIGNANT CHOLERA: its Origin, Pathology, Treatment, and Mode of Prevention.** With an Appendix on Cattle Plague as compared with Cholera and other Human Maladies. A Letter on Homeopathy; its false inferences and hollow Assumptions. With an Essay on the Present State of the Medical and Veterinary Professions in this Country. Pp. 135. London: Hardwicke. 1866.

The treatise by Dr. Shrimpton was originally written in French, and is evidently founded upon experience gained in France, although copious references are made to other sources of information. The author's opinion as to the nature of cholera is, that it is due to an affection of the nervous system of organic life, that it seizes the whole organism at once, that its influence penetrates the most intimate structures of the body, and that it alters the state of vitality in the elementary cells which constitute the organic tissues. He repudiates the idea of contagion being a means of propagating the disease, and therefore condemns the adoption of quarantine laws for its prevention.

Dr. Peters, who is an American physician, has witnessed the epidemics of cholera in 1849, 1854, and 1866, and has seen every variety of treatment practised at the cholera hospitals. He considers that the disease is portable and communicable, that the quality of infectiousness belongs peculiarly, if not exclusively, to the matters evacuated by the patients, and that the true counteracting and remedial agencies are to be found in the processes of disinfection. He urges the maintenance of a strict quarantine at the ports where cholera is likely to be imported.

Dr. Edwards Crisp's *brochure* consists—first, of an Essay on Malignant Cholera, read at the Medical Society of London in 1849, and which contains some very elaborate statistics, and some bold and original views. Dr. Crisp is entirely opposed to the so-called eliminative treatment of cholera. The second part of the pamphlet is an appendix on a number of subjects of interest to the profession and the community. In reference to the cattle plague, Dr. Crisp has collected a great amount of information, and his vigorous letters exposing the shallow sophistries and absurdities put forward by the *Times* at the period when the cattle plague was beginning its ravages, will be read with amusement and interest. It is to be hoped that his arguments made some impression on the persons to whom they were addressed, but whether they did or not, they will well repay perusal. His exposure of homeopathy is excellent, and ought to convince even the homeopaths themselves of the fallacy of their tenets.

**A STATISTICAL INQUIRY INTO THE SANITARY CONDITION OF KINGSTOWN.** By Dr. THOMAS MORRIS MADDEN, M.R.I.A. Dublin: J. F. Fowler. 1867.

**ON INSANITY AND THE CRIMINAL RESPONSIBILITY OF THE INSANE.** SAME AUTHOR. Dublin: J. Falconer.

The first pamphlet consists of a posthumous letter by the late Mr. C. Halliday to the Commissioners of Kingstown, with introductory observations by Dr. Madden. Unlike letters, which contain their essence in the postscript, in this case it is the introduction which is the most important. After our late visitation, and the apparent deplorable state of Kingstown in a sanitary point of view (we use this expression on the authority of Dr. Madden), these observations come most opportunely.

At page 8 the author gives the localities where the seventy-three adult deaths were distributed; also the localities and number of sick calls. These two lists bear a certain relative proportion, and it is a pity that a third column was not introduced, giving the number of inhabitants in each street or locality, otherwise these tables do not give much information to those who are not well acquainted with the town.

A case in connection with disinfection by carbolic acid is here mentioned which has happened more than once—namely, that the permeation of organic poison in the form of sewage, &c., into wells was discovered by the use of the disinfectant. This is a decided advantage possessed by this antiseptic, for it

is not itself poisonous when diluted, but a very minute quantity disseminated through a very large bulk of water gives a disgusting taste to the latter. Thus, when mixed with sewage it acts as an indicator to the palate of the presence of its tasteless but poisonous companion.

We recommend Dr. Madden's book particularly to the consideration of all interested in Kingstown or its neighbourhood, if for no better reason, for that of self-interest. It must be borne in mind that for a short period cholera raged in this small town with greater virulence than in London or Dublin.

In the second pamphlet the author's views are perhaps best explained by the following quotation from page 10. The author is not one who thinks that all crime is the result of partial insanity. Mere passion is not madness, but criminal responsibility does not exist with the insane:—

"Nor should any so-called irresistible impulse, not connected with a diseased brain, nor any emotion or custom which is not of itself a proof of insanity, be considered as conferring immunity from the just punishment of crime. None are free from passions or impulses, which, if they be not checked, may become almost irresistible from habit, and may lead to crime; but in such cases the perpetrators of crimes being accountable for the acts by which the control over the passions was originally weakened, they are equally accountable for all the consequences that may arise therefrom. A madman is not thus responsible, not being answerable for the diseased action in his brain whence the insane act proceeds."

Both those pamphlets will be read with interest.

**THE STORY OF THE TRUCK; OR, THE WHY AND WHEREFORE OF CATTLE DISEASES.** By WM. REID. Edinburgh. 1867. pp. 140.

We have read Mr. Reid's pamphlet with much satisfaction as well as regret. Satisfaction at finding so practical and simple a remedy suggested for the prevention of the great cruelty to which cattle are subjected on many lines of railway—namely, the privation of water for long periods—in some cases, as Mr. Reid tells us, of "from forty-eight to sixty hours;" and regret that this pamphlet should still be necessary to call attention to so great a cruelty. If we have the right to kill cattle for our use, we have assuredly no right to torture these dumb creatures beforehand by the slow torment of unsatisfied thirst. That it is as impolitic as it is inhumane to do so is evident, for cattle brought up to the market from remote districts without water frequently arrive in a state of fever which renders the meat unwholesome and innutritious, as well as lowers its market value. Therefore, on the ground of public health, as well as on the score of humanity, we should be glad to see the use of Mr. Reid's railway water-truck, or some other equally good system for supplying cattle with sufficient water during all railway journeys, rendered compulsory by law.

**OBSERVATIONS ON THE COMPARATIVE ADVANTAGES OF AFFORDING OBSTETRIC ATTENDANCE ON POOR WOMEN IN LYING-IN HOSPITALS AND IN THEIR OWN HOMES.** By DENIS PHELAN, M.R.C.S. London. Late Poor-Law Medical and General Inspector.

The subject discussed by Mr. Phelan in these "Observations" is one on which it is extremely difficult to arrive at a satisfactory conclusion. Mr. Phelan treats the subject under two heads:—"1st. Which mode of attendance is the least expensive, assuming each to be efficient; and 2ndly. By which is there less loss of life of mothers and children?" On both these points Mr. Phelan's conclusions are in favour of attending parturient women in their own houses as a general rule. He says:—

"It seems to follow from the foregoing data and observations that one mode of lessening the mortality of lying-in women in hospitals is, to limit the admissions to the classes that more particularly require hospital treatment, and to give extern attendance to those that do not. This opinion has been expressed in reference to the Rotundo by four different Boards of Commissioners, which have examined and reported on it, and is expressed by the commissioners appointed to report on the Dublin hospitals in 1855."

Mr. Phelan's statistics are all taken from official and published documents, and some of the facts adduced by him from these sources are very remarkable. We shall quote a few lines from pp. 7 and 8:—

"The Dublin Rotundo Hospital Statistical Table shows that 8224 births took place in that institution in the seven years

ended 1864, and that 252 mothers died, which is one in thirty-two two-fifth births. During these seven years 3142 deliveries took place in the Coombe Lying-in Hospital, and 45, or one in 70, died."

"During the seven years ended 1864, 617 women were attended from the Dublin Rotundo Hospital, and ten, or one in 62, died."

"During the same seven years the Coombe medical officers attended 4473 at their homes, with the loss of twenty mothers, or one in 223."

Without in the least undervaluing the amount of labour and perfect accuracy evinced by Mr. Phelan in every page of this important essay, we would venture to remind him that all medical statistics are more or less open to the charge of fallaciousness, no matter what pains the compiler may take to ensure their accuracy. And we who have had occasion in our time to attend labours in some of the poorest quarters of Dublin, and have had to witness the indescribable scenes of squalid poverty and misery in which the wives of the poor so often have to bear the throes of parturition, cannot but contrast with this the comforts, the unfailing kindness, and the eminent professional skill with which these poor women are treated in the Rotunda Lying-in Hospital. Most sincerely do we trust that this great institution, the noble monument of the humanity and charity of an Irish physician, may long continue to contribute to the alleviation of the suffering poor of Dublin. To the enlightened physicians who preside over that excellent institution, and to all others interested in the important question we are now considering, we would recommend the perusal of Mr. Phelan's very able and valuable paper, although we must add that we do not coincide in all his views.

### THE ACCOMMODATION OF PAUPER LUNATICS.

THE report, which appeared a few days since in the daily papers, of a conversation held at a late meeting of Middlesex magistrates, on the subject of some irregularities at the Colney Hatch Lunatic Asylum, forcibly impresses upon the mind the unsatisfactory arrangements at present made for the reception and care of our pauper lunatics. In the particular instance to which we refer, it was shown that some of the inmates of the Asylum, who were especially dirty and disorderly, were subjected to some species of punishment or coercion, which, however, was entirely disapproved by the Commissioners in Lunacy, who expressed their disapprobation in very strong terms, and intimated their hope that no such repressive measures would again be adopted.

Now, without in any way disputing the views

held by the Lunacy Commissioners in this case, we cannot help remarking upon a point which must have struck any one who has visited either or both of the great County Asylums of Middlesex—namely, the enormous size of these institutions, and the great multitude of patients confined within their walls. When we are told that 900 insane patients at Colney Hatch are placed under the care of a single medical man, we can easily believe that he has had imposed upon him a labour far greater than any one man can perform. The mere classification of such a crowd must be a matter of difficulty, the prevention of irregularities among such an assemblage must be often impossible, while individual attention to each case is wholly out of the question. Hence the cases must be taken in groups, and while the quiet patients may be in general safely left without much supervision, the noisy and the dirty ones must almost of necessity be segregated from the rest and placed under some sort of control, in order to prevent mischief.

When we view such an institution as the Colney Hatch Lunatic Asylum, with its 2000 patients, or thereabout, and its *two* superintending Medical Officers, we are only amazed that irregularities do not more frequently occur; while it is hopeless to expect from such officials, so thoroughly over-worked, any additional contributions to our existing stock of psychological knowledge, or indeed any very energetic or sustained efforts to alleviate the mass of mental disease placed under their supervision.

If a Medical Superintendent were to devote his whole twenty-four hours exclusively to the patients under his care, he would have less than *two minutes* a-day to bestow upon each of the nine hundred lunatics placed in his charge; but when it is considered that a medical man must eat and sleep like other human beings, to say nothing of reading and exercise, it is obvious that he cannot satisfactorily do his duty, more especially when he has to write out reports, to superintend the nurses and warders, to receive new patients, and to discharge old ones, besides the host of other routine duties imposed by his position.

Notwithstanding, however, the crowded state of the Middlesex Lunatic Asylums, and indeed of many other Lunatic Asylums in England and Wales, the English Lunacy Commissioners are still using all their endeavours to crowd still more of the insane population into these institutions, and even to visit with punishment persons who detain pauper lunatics in private dwellings. The consequences have been that the Asylums have become so overcrowded as to be in many instances almost unmanageable, as far as classification and treatment are concerned, and that those who cannot be received within them are kept in the Workhouses or are sent to Private Asylums. Again, in consequence of the great kind-

ness very generally and most properly bestowed upon insane patients in the County Asylums, the liberal diet accorded to this class of persons, and the excellent hygienic arrangements adopted in the buildings, the relatives of insane paupers are often too glad to avail themselves of the facilities afforded them of getting rid of their incumbrances, and shifting from themselves to the general public the cost of their maintenance. Thus, in comparing the statistics of lunacy in the present day with those of former times, it would appear as if lunacy was on the increase beyond the proportion indicated by the increase of the population; whereas, although there can be no doubt that lunacy has really increased very much of late years, yet the apparent excess is mainly due to the fact that the insane persons, formerly kept by their relatives in private houses, are now sent in far greater numbers than formerly into the public asylums.

Among this great crowd of insane paupers, the curable cases bear but a very small proportion to the incurable, the latter including a great multitude of patients who are afflicted with chronic imbecility or dementia, who are in no way dangerous either to themselves or others, and who live probably to a great age, and thus occupy the space, and involve the expense, and command the care which would otherwise be bestowed upon cases of a more recent and hopeful, though perhaps more immediately dangerous character. The latter cases are therefore, of necessity, often kept in the Workhouses, at least for some days or weeks, while room is being made for them at the Asylums, and the period of doing them good is thus allowed to slip away.

The Workhouses, unable to relieve themselves of the pauper lunatics by drafting them into the Asylums, are often necessarily obliged to keep them; and then arises the clumsy compromise made between the Poor-law Board and the Lunacy Commissioners and the local Guardians, whereby it is allowed that the Workhouses shall in certain instances, receive and keep the lunatics within their walls. We call this a clumsy compromise, for the Workhouses are both Lunatic Asylums and are not Lunatic Asylums, since on the one hand the Lunacy Commissioners and the Poor-law Board sanction the admission and retention of lunatics in some of the Workhouses, whereas, on the other hand, it appears from legal opinions which have been given to the Poor-law Board and the Lunacy Commissioners, that the local Guardians have no authority to detain a pauper of unsound mind against his wish to be discharged, *unless the insane person is dangerous to himself or others*, and the *onus probandi* would be thrown on the Board of Guardians in case any insane pauper, or alleged insane pauper, were to bring an action against them for illegal detention.

We are aware that Mr. HARDY'S new Poor-law

scheme contemplates the erection of district Asylums for the insane paupers of the metropolis, and if this part of the plan should be carried out, many of the evils to which we have alluded will be obviated, for in fact the Middlesex Asylums of Hanwell and Colney Hatch would then be immediately relieved of many of the applications which would otherwise be made for admission. But the question still remains whether it is necessary that all the insane paupers, of every class, should be received into gigantic and costly buildings and there kept for life at great expense to the nation. An opinion has lately been gaining ground that many of the harmless lunatics, of whom there is a very great number, might be with perfect safety kept in detached houses scattered through the country, and maintained at about the same rate as ordinary paupers, and this opinion, indeed, is entertained and acted upon by the Scotch Lunacy Commissioners. Between the views of the latter who approve and sanction the retention of lunatics in private dwellings, and those of the English Lunacy Commissioners who wish to drive them all, whether private or pauper, into gigantic and overgrown asylums, perhaps a middle course might be found, for it cannot be denied that the present condition of insane paupers in England, although in theory very defensible, is creating very much discontent and acts with great inequality. The great Asylums are becoming mere refuges for the hopeless class of imbecile and harmless lunatics, while the curable and violent cases are too often left in the Workhouses where the appliances for treatment are inefficient, and where the Guardians are without legal power.

#### THE OBSTETRICAL SOCIETY OF LONDON AND MR. BAKER BROWN'S OPERATION.

It is only a few weeks since we had occasion to comment on a debate which occurred at a meeting of the Obstetrical Society, and which—replete with personalities—seriously detracted, in our opinion, from the dignity of the Society. We have now to recur to the subject in connexion with an *embroglio* which came off on Wednesday evening last, beside which the previous discussion was tame and spiritless. The Council of the Society had, it appears, decided to exercise the provisions for expulsion of a Fellow on account of “the published matters in relation to the performance of clitoridectomy.” Who the Fellow was and the *modus operandi* will be learned from the following correspondence circulated by Mr. BAKER BROWN:—

“136, Harley-street, Cavendish-square, W., March 1st, 1867.

“SIR,—On Wednesday evening last I received the following note. I will now merely observe that I have had no opportunity of hearing what specific charges are made against me. I have never, therefore, had an opportunity of meeting them. I am simply informed that notice of expulsion will be read on Wednesday next by the Presi-

dent. I will, therefore, only say that what is my case to-day may be your case to-morrow, and ask you to suspend your judgment until placed in possession of the charges and my reply thereto. "Yours truly,  
"I. B. BROWN."

"53, Berners-street, Feb. 27th, 1867.

"SIR,—We are directed by the Council of the Obstetrical Society to forward to you a copy of the following resolution, passed at special meetings of the Council held on the 15th and 25th inst., for the purpose of considering two letters addressed to the President and Council by Mr. I. Baker Brown :—

"That, in the opinion of this Council, the published matters in relation to the performance of clitoridectomy by Mr. I. Baker Brown, justify the Council in recommending the Society to put in force against him Law IV., Section II., which provides for the expulsion of a Fellow."

"We are, sir, your obedient servants,

"G. C. P. MURRAY, M.D.,  
"HENRY GERVIS, M.D., } Hon. Secs.

"To I. Baker Brown, Esq."

"CHAPTER IV.

"Of the withdrawing and removal of Fellows.—1. A Fellow may withdraw from the Society on paying any contributions that may be due from him, and signifying his intention in writing to the President.

"2. Whenever there shall, in the opinion of the Council, appear cause for the removal of a Fellow, the same shall be notified by the President of the Society at the next ordinary meeting, and a notice forthwith sent to every Fellow of the Society, making the next meeting special, for the purpose of considering such removal. If, on a ballot taking place, two-thirds of the Fellows present shall vote for the removal, the President shall declare the Fellow in question removed accordingly. At such ballot, fifteen Fellows, at the least, must be present."

We will not, we trust, be open to the suspicion of favouring a particular operation, or of coquetting with any illegitimate practice of our profession, in animadverting on the very unusual course pursued to Mr. BAKER BROWN in this matter. The affirmation or condemnation of an operation lies with the judgment of the profession, not with us. The action of the Council of the Obstetrical Society, however, is altogether outside the merits or demerits of clitoridectomy—its use or abuse; and in the resolution to expel Mr. BROWN is opened to us a great ethical question of the deepest professional interest, and which must not be blinked by any fear of defilement in its discussion.

We find it impossible to give in full the report of the wrangle between Councillors and Members. It is sufficient to say that the President, in accordance with the bye-law, notified to the Society the recommendation of the Council that Mr. BROWN be expelled as a preliminary to the general ballot *pro* or *con* at the next meeting. It would naturally be presumed that, in asking the Society to outlaw one of its Fellows—to place on him such a brand that he could hardly expect to be met in consultation as a gentleman and a man of honour, the Council would be prepared to produce condemnatory evidence of sufficient gravity to justify it in this step; but it appears that the Council has no more specific indictment to lay than "the

published matters," and they ask the Society to content itself with this very vague innuendo for a whole month, till the next meeting in April. This is a course neither just, temperate, nor dignified; neither fair to the accused nor convincing to the profession. The Council have, intentionally or not, acted on the military principle—more wholesome at war than in medicine—to hang the culprit first and try him afterwards. Do they think that the red blot which they have placed so rashly against Mr. BROWN's name can ever be erased by any vindication, however triumphant? and how is it that it did not occur to them to hear Mr. BROWN's defence, and place it with the charges which it is intended to meet before the profession, before ostracising him.

The debate eventuated in an assurance from the Council that the "causes of the removal" would be placed in the hands of the Fellows within ten days or a fortnight. So far so good; but is Mr. BROWN to have an opportunity of defending himself? If he has not, we venture to say that the verdict of the Society will be as worthless as that of the Council, and if condemnation be deserved it will fall impotently. When we see on the Council men who have publicly committed themselves to a course of hostility to the accused, we see a danger lest our profession should be brought into contempt by the installation of a modern secret inquisition in our ranks. Whatever be the consequence, the profession will not sanction persecution in any form. It must never be possible to say that professional jealousy or personal pique has been allowed to drag through the mire the honour and reputation of any brother, yet these remarks need to be repeated, because already fair play has scarcely been given. Thus in every trial it is the custom of journalists to refrain from comments prejudicial to a prisoner pending the verdict, nevertheless we regret to find, however, that some of our contemporaries have already been writing with an evident bias against Mr. BROWN. This is certainly a step too far. Mr. BROWN is accused—the Council are his accusers—the Society is the jury; we demand that the accused who is now on his trial, not before a star chamber tribunal, but before the whole profession, shall be permitted to justify himself if he can; and we earnestly trust that no Fellow will weaken the strength of his acquittal or condemnation by a prejudiced or uninstructed vote.

### Notes on Current Topics.

OBSCENE PAMPHLETS.—We have several times lately alluded to the abominable productions of the tribe of filthy quacks that are thrust into the hands of young men passing along the streets, and invoked the strong arm of the law to put down the nuisance. It is a matter of regret that Parliament has not yet seen fit to take action in this

matter. If the existing law be insufficient to protect our youths from this onslaught, it is time that an act were passed for the purpose. The instances of this evil brought to our notice cannot all be described in our columns, and if they could, we greatly fear it would not tend to abate the nuisance. The impunity with which at present this nefarious trade has flourished, lead these heartless scoundrels to spread their nets wider and wider. Not only our large towns, but even villages and country districts are becoming invaded by these destroyers. An infamous little pamphlet has been sent to us by an esteemed correspondent from Scotland, who very pertinently asks whether the Glasgow University Council should not be communicated with. That the matter concerns the honour of the University seems clear from the following passage of our correspondent's letter:—

"The enclosed filthy little publication is sown broadcast through our country towns by a seedy looking gentleman, who adopts the cowardly plan of slipping it beneath the door, or throwing it into the lobby. The author is, as he says himself, a Graduate of Glasgow University, and placed on the Register. What are the benefits of Medical Registration when such doings are allowed on the part of those who are on the Registration Roll. Until a Medical enactment is equal to crushing such filthy emanations, we must pronounce Registration a mockery and a delusion."

**A MEDICAL VIEW OF THE REFORM BILL.**—It has no doubt appeared strange to not a few in our profession that a Government which professed such a desire to avoid the "swamping" of the educated classes by too free an extension of electoral privileges, and to prevent that, has devised a number of "fancy franchises," should evince such an insensibility to the claims of medical men for representation. The church and the law have immense influence in both houses of Parliament, but medicine is powerless to protect its own interests or advance those of the Commonwealth. The disdainful manner in which the Chancellor of the Exchequer rejected the advocates of the Scotch Universities is a curious comment on the abundant professions of the government. Had he been sure that these venerable institutions would be true to his party, we suspect he would have been very eloquent on the claims of education. He offers one member to the University of London, a sort of sop to the truly liberal professions, which we declare utterly insufficient. Had he offered each of the Scotch Universities a member, and another to the Queen's University in Ireland, it would at least have been a proof of the sincerity of his desire to increase the influence of education. It is strictly in accordance with the constitution to give members to the Universities, and with those of Oxford, Cambridge, and Dublin returning two each, the offer of one to the London is but a niggardly recognition of intellect—a proof that with all Mr. Disraeli's enthusiasm for educational and fancy franchises, learning has little to hope for at his hands.

**CASUALS AT CLERKENWELL.**—Another investigation into the management of the Clerkenwell casual wards has produced more astounding revelations than those on which we commented a few weeks since. The inquiry has ended in the superintendent and his wife being called upon to resign. This proposal having been substituted for the more energetic one of a resolution to dismiss them. The revelations are really so shocking that it is not surprising the guardians should apparently wish it to be understood that some of the most cruel and abominable

practices have already been discontinued. Little comment is needed on the facts that turned up during the inquiry. The case was brought forward by Mr. Bassinger, a parishioner of Clerkenwell, who stated that on passing the wards one wet evening, about nine o'clock, he saw a woman outside, to whom the superintendent, Runciman by name, was refusing admission. Mr. Bassinger and other persons applied to the superintendent to admit the woman, but Runciman told them to go away, accompanying his demand by the assertion that they were costermongers and criminals, acting, so the witness described, in a filthy manner towards Mr. Bassinger's son. Mr. Dalton, a person residing in the neighbourhood, said he was in the habit of passing by these wards, and had often seen persons refused relief, and had seen disturbances there. The woman, he said, was not intoxicated, and he felt very indignant to think that a woman should be kept out on the wet stones. Mrs. Gibbs, a resident in Clerkenwell-close, near the casual wards, also deposed to hearing the bad language used by Runciman. She deposed to Runciman's violent and insulting behaviour towards herself on more than one occasion, and then stated that the casuals had to pass naked through an open yard in the rear, where they could be seen by the neighbours, declaring that she had been obliged to move in consequence, as she had a growing family. Runciman denied using bad language, and called the porter and a policeman as witnesses, but the guardians seemed to place no reliance on the testimony they offered, and adopted the resolution we have named.

**THE CHOLERA IN JERSEY.**—The medical authorities have been strangely at odds with regard to the real nature of the disease which has appeared in that island, some without hesitation pronouncing it cholera, others as decidedly declaring that it is not, though doubtful as to its true character. Possibly the reports which were circulated there, and which have reached us, may have occasioned more alarm than need have been, inducing many hastily to leave the island and preventing others from going there, which has interfered with its welfare in many points of view. BETHIS as it may, the epidemic has spread widely and rapidly in one or two localities, and has been followed by considerable mortality. Up to the 28th of last month the total number of cases reported was 130, of which 53 had died, 59 were restored to health, and 18 were still under medical care; but as decided sanitary measures have been adopted, the cases were gradually becoming fewer, and on the day above mentioned no deaths were reported, so that there is every reason to hope that before long the epidemic will entirely disappear.

**SCURVY STATISTICS.**—This subject was referred to in our pages a few weeks ago, and our attention is drawn to it again by a fresh importation of this disease into the country in British ships. By inquiry it was found that 20 cases were brought by two of those vessels, and no less than 42 by five others, making 62 during the past two months of the present year. Of these, 30 were received at the *Dreadnought* Hospital. The Board of Trade made investigations with regard to four of these vessels. As yet little has transpired; but it was found, at an inquest held at Greenwich, from the evidence of Dr. Dickson, R.A., one of the inspectors, that on board one of these vessels, instead of lime-juice, a dilution of citric acid was made use of. Both Dr. Dickson and Mr. H. Leach declared this to be useless as an anti-scorbutic agent.

## Summary of Science.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES R. C. TICHBORNE, F.C.S.L., F.R.G.S.I., &c.

[THE Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

### ON THE ELIMINATION OF NITROGEN BY THE KIDNEYS AND INTESTINES DURING REST AND EXERCISE.

By Dr. PARKES.

SOME time since we referred to Professors Fick and Wislicenus' experiments, and Dr. Parkes' experiments were undertaken to test the results arrived at by those professors with respect to the elimination of nitrogen, during exercise, on a non-nitrogenous diet, as recorded by them in the *Philosophical Magazine* of June. Dr. Parkes' paper appears in the proceedings of the Royal Society, No. 89, Vol. xi. The last named gentleman experimented upon two intelligent and healthy soldiers belonging to the Army Hospital Corps. He remarks that the satisfactory results of his experiments were owing essentially to the very great care with which these two men carried out every rule which is laid down, and remarks that when soldiers are steady and trustworthy they are very good subjects for experiments of this kind. Dr. Parkes is, no doubt, right to a certain extent; but such experiments must, in this respect, be inferior to those executed by the professors on themselves. The author divides his experiments into five periods—viz.: 1st. The men were kept under observation for six days, in order to determine the varieties in weight, and in the excreta; and to see if the metamorphosis of tissue appeared healthy. 2ndly. The men were placed for two days on a non-nitrogenous diet, consisting of arrow-root, sugar, and butter, from which the casein had been separated; the only nitrogenous substance was tea. 3rdly. The men returned to their former regulated diet for four days. At the end of these four days the weight of the body in each man had returned almost exactly to its former amount. 4thly. The diet was the same kind as in the second period (non-nitrogenous), but with exercise for two days. 5thly. Period was for four days, when they were again placed upon their ordinary diet with exercise. The men were not stinted in the amount of food they eat, but the quantity was carefully noted. We cannot give Dr. Parkes' tables, suffice it to say, that each day the nitrogen and intestinal excreta, urea, chloride of sodium, and phosphoric acid, were determined each day, and that he comes to the conclusion that they are not altogether in accordance with Professors Fick and Wislicenus' experiments.

The decrease in the urea during the first thirty-six hours of the exercise-period, as compared with the rest-period on a diet without nitrogen, which occurred in these two men, is, says Dr. Parkes, conformable with the results obtained by the two experimenters mentioned, but this is not the case with the increase in the urea which was found in the last twelve hours.

Yet that this increase is real is shown by the accordant results in the two men, and by the increase of the total nitrogen of the exercise-period, as determined by soda-line.

The author then proceeds:—

"The relative greater increase in my experiments of the non-ureal nitrogen, which makes me believe that an excess of nitrogenous compounds other than urea, and possibly creatinine especially, was produced by the exercise, is not perceptible in their experiments; yet, I cannot but believe that the fact was so, as it comes out with great clearness in the two men. Relation of ureal to non-ureal nitrogen, the former being taken as a unity:—

	S.	T.
Before rest-period ...	1 to 11	1 to 1,108
Rest-period ...	1 to 1,042	1 to 1,13
After rest-period ...	1 to 1,009	1 to 1,116
Work-period ..	1 to 1,126	1 to 1,178
After-work-period ...	1 to 1, 08	1 to 1,06

(three days.)

"The reason which makes me believe the results are real, is the fact that the individual relation of the ureal and non-ureal nitrogen is preserved; that is to say, in T the non-ureal nitrogen is, under normal circumstances, a little in excess as

compared with S. The same relative excess is also found in the work-period. The reason of these differences between Professors Fick and Wislicenus, and myself, is probably to be found in the short period of time during which their observations were carried on; and also, because the urea was not determined by them on the night of the 30th to 31st of August.

"But their conclusion is certainly borne out, that on a non-nitrogenous diet exercise produces no notable increase in the nitrogen of the urine, although when the whole period is considered it does produce a slight increase.

"It may now also be said that under similar conditions exercise produces no increase in the excretion of nitrogen by the bowels."

The diminution in the amount of urea during the actual period of work, as compared with the rest-period, which, if I am not mistaken, is obvious in both our experiments, is a very curious circumstance. It shows, not that on a non-nitrogenous diet, the nerves and muscles are totally unaffected by exercise, but that changes go on which either retain nitrogen in the body or eliminate it by another channel.

It is possible that when the excess of nitrogen is restricted the exhausted muscle will take nitrogen from the products given off from another portion of decomposing muscle, and thus the nitrogen may be used over and over again; or, after all, is nitrogen really given off in some form by the skin during exercise as formerly supposed?

Although it is certain that very severe exercise can be performed on non-nitrogenous diet for a short time it does not follow that nitrogen is unnecessary. The largest experience shows not only that nitrogen must be supplied if work is to be done, but that the amount must augment with the work. But, for a short period, the well-fed body possesses sufficient nitrogen to permit muscular exertion to go on for some time without fresh supply. "But the destruction of nitrogenous tissues in these two men is shown by the way in which, when nitrogen was again supplied, a large amount was retained in the body to compensate for the previous deprivation. I believe also that in these two men the great exhaustion of the second day showed that their muscles and nerves were becoming structurally impaired, and that, if the experiments had been continued, there would have been on the third day a large diminution in the amount of work. I have found that the period when a restricted supply of nitrogen begins to tell on the work differs in different men. In one experiment I reduced the nitrogen in the food to one-half its normal quantity in two men. In one no effect was produced in exercise in seven days, in the other a lessening of active bodily work was produced in five days. Doubtless the previous nutrition of the muscle would influence the time."

Finally, it may be questioned whether the relation of elimination of nitrogen to exercise can be properly determined in this matter—i.e., by cutting off the supply of nitrogen.

The true method would probably be to supply nitrogen in certain definite amount, so that the acting muscle might appropriate at once what it required.

### ON THE SEPARATION OF THE SALTS OF STRICHRINE BY PHENIC ACID.

M. P. Bert says that on agitating a weak solution of hydrochlorate of strychnine with a few drops of phenic acid the solution takes the appearance of an emulsion. It then is found to be nearly inactive when administered by the *hypodermic* method; but this inactivity is simply due to slowness of absorption, and not to any chemical change in the composition of the alkaloid. On adding ether, a bright solution is produced, which is as active as ever.

### ARSENIURETTED AND ANTIMONIURETTED HYDROGEN.

M. Drugendorff discriminates between those two bodies by passing them over fragments of white caustic potash. The antimony leaves a brilliant metallic coating upon the potash. The arsenical compound produces no change.

### ON THE PREPARATION OF MEDICAL TINCTURES.

On speaking of the relative merits of percolation and maceration, M. Filhol (*Journal de Pharmacie et Chimie*) says, that stronger tinctures can be made by percolation, but that by the latter process they keep better and are less liable to become rancid. He is of opinion that alcohol is not as good a preservative as it is generally supposed, and that certain immediate principles of vegetable origin alter when dissolved in alcohol. A tincture beautifully green, from the presence of chlorophyll, will undergo transformations on treating with hydrochloric

acid, which M. Fremy has described. These changes do not take place in a tincture which has been kept some time. The petals of the ranunculus macerated in alcohol gives a golden yellow tincture, which, on the addition of hydrochloric acid, turns green. After the liquor has been filtered a yellow substance remains on the filter, and a fine blue liquor passes through. Nothing of the kind takes place when the tincture has been kept some time. The solutions remain yellow. Good tinctures can be prepared from leaves and flowers well dried. It is therefore better to preserve the plants than the tinctures, and the latter should be prepared in small quantities and used as fresh as possible.

#### ON THE ESTIMATION OF ORGANIC MATTER IN WATER.

M. F. Bellamy, in a communication in the *Journal de Pharmacie et de Chimie*, January, refers to what is pretty generally known amongst practical chemists—viz., that the determination of organic matter in drinking water by permanganate of potash is dependent upon the nature of the organic matter present. He proposes to estimate the organic matter by burning it with oxide of copper in a glass tube, and passing the evolved gases through a solution of baryta, and the carbonate of baryta estimated by a volumetric solution of nitric acid. We do not exactly see why the author should fix upon the carbon for the approximate determination of organic matter. The determination of the nitrogen would, in our opinion, be a more important point in the examination of potable waters.

#### ON THE BONES OF BIRDS AT DIFFERENT PERIODS OF THEIR GROWTH.

Experiments are given by Dr. J. Davy (Proceedings of the Royal Society) as having been made with the following birds:—Common fowl—duck, goose, turkey, pheasant, partridge, grouse, rook, common crow, owl, sparrowhawk, buzzard, blue-tit. From these results the following conclusions may be drawn:—First. That at an early stage, and up to a certain period of growth, marrow exists in the bones specified of all the birds named, and that about the time of hatching the medullary tissue abounds less in oil or fatty matter than at a later period, the proportion varying in different instances; least, probably, in birds of prey, such as the buzzard and owl, most in birds the food of which is mostly vegetable, such as the goose. Secondly. That the substitution of air for marrow in those bones which are essentially hollow varies as to time in different species—is earlier in the rook, the crow, the grouse, the tit than in the common fowl, the duck and goose, especially the latter. The exchange of one for the other having probably some relation to the time of taking wing and the use of the parts, and in accordance the humeri, except in the instance of the sparrowhawk, seemed to have the marrow absorbed somewhat earlier than the femora. It may be conjectured that, like the residual yolk in the young bird, the marrow in the bones in question may serve in part as food, nourishing in the act of its removal. As regards the quality of marrow in the bones of different birds, the trials Dr. Davy has made have been very limited. He is disposed to infer from them that, besides differing as in many instances it does in colour, it may differ also in composition, in the proportion of adipose matter and its kind, and in the proportion of albuminous matter; in some, as in the bones of the goose, oil most abundant; in others, as in those of the rook and buzzard, albuminous matter and fat of the stearine kind. Even in the bones of birds of the second kind—viz., the woodcock, blackbird, water-ouzel, martin-swift, sparrow, greenfinch, titlark, stonecleat, blackcap, canary, yellow ammer, little sand-pipe—such as their long bones, there is a difference in this respect. Of these, all that the author has examined sink in water with the exception of the femora, which only partially sink, the marrow in them being less rich in adipose matter and consequently in drying contracting more, and as before remarked admitting more air. As to the marked difference of birds of the two kinds in relation to the condition of their bones, the rationale is not obvious. Perhaps an approximation to the truth, or to the probable, may be made by comparing the bones of birds of the two kinds which are possessed of similar powers. The swift, for instance, and the buzzard, rivals in swiftness of flight and enduring power of wing. How different are their humeri! says Dr. Davy. The former very strong, short, and compact, provided with firm and large processes for the attachment of muscles; in the latter long, hollow, and light, and comparatively brittle, yet sufficiently firm to bear without fracture the muscles which act on them. Here have we not, after a manner, a kind of substitution of qualities? Great strength and extended sur-

face in small space in the one, for lightness with greater length of leverage in the other. Further, the one kind of bone, that which contains marrow being less brittle than that which contains air, and more yielding, may be less liable to fracture—a quality which in the bird, before ossification is complete, may be of essential service; it may perhaps serve to account for the bones which are eventually hollow having primarily marrow in place of air.

#### SOLUBLE GLASS FOR BANDAGES.

M. Velpair proposes to use soluble glass in place of starch, plaster of Paris, &c., now used for bandaging fractures. It is said to form a firm support, and becomes quite hard in two or three hours, yet it is readily removed by moisture.

#### MORPHIA AND STRYCHNINE.

M. Rodgers says that the reaction between strychnine and bichromate of potash may be masked by morphia; but these two bases may be separated either by chloroform or benzole, which dissolves the strychnine, but not all the morphia.—*Chemical News*.

#### SILISIC ACID.

M. Frémy states to the members of the Academy of Sciences that silisic acid exists in two isomeric states. The first of them he calls metasilic acid; its equivalent is  $(\text{Si O}_3)_3$ . It is triatomic, and forms, with bases, three series of salts:—

The second isomeric state  $\text{Si O}_3$  is what constitutes quartz. This also forms three series of salts being triatomic, but has not the same equivalent.

## Proceedings of Societies.

### MEETING OF THE HARVEIAN SOCIETY,

21ST FEB., 1867.

Dr. POLLOCK in the Chair.

MR. DE MERIC read a paper on

#### SOME COMPLICATIONS OF GONORRHOEA.

The author offered a brief sketch of the common complaint called gonorrhœa, and stated that some urethral discharges were independent of contagion, very simple, easily controlled, and, in general, free from complication; whilst others were just the reverse. The first kind of discharge might conveniently be called urethritis, the second true gonorrhœa. On two complications of the latter—namely, gonorrhœal rheumatism and gonorrhœal ophthalmia, he wished to present a few remarks. He related with full details, the case of a gentleman lately under his care, where both complications had occurred. The facts of this case led to the inquiry whether the joint complication was really dependent on the urethral discharge, or whether it was a mere coincidence. The author believed in this dependence, and for the following reasons:—1. Because there was a pathological sympathy, independently of gonorrhœa, between the inflamed urethra and the joints. 2. Because the articular affections had, by many observers, been noticed to exist along with the urethral discharges. 3. Because in certain subjects joints had been known to suffer at each new attack of gonorrhœa. Those, on the other hand, who considered the so-called gonorrhœal rheumatism as a mere coincidence, alleged that the joint complaint was observed but rarely, compared with the enormous number of cases of gonorrhœa. This the author not only conceded, but corroborated, by saying that he could, from his own practice, cite but three cases in hospital patients, and seven treated in private. The common cases of rheumatism, therefore, had nothing to do with the joint complication in patients suffering from gonorrhœa; and we were driven to believe that something peculiarly predisposing must exist in the individual, which, added to the existence of the gonorrhœa, gave rise to the inflammation of the synovial membrane of the joint, or the ocular conjunctiva. Nor should it pass unnoticed that the discharge must be bona-fide urethral to generate the complication, as discharges from the glans, prepuce, vagina, vulva, or uterus were never connected with rheumatism. Hence the rarity of the complications among women. He had, however, observed one case of this kind. The author

now referred to the joints usually affected, and stated that out of ten cases, six suffered in one or both knees, one in the hip, one in the articulation of the jaw, one in the ankle, and the tenth in several joints at the same time. Mr. DeMerie then entered into some details respecting these cases, and said that he had not met with any where the tendinous sheaths, bursæ mucosæ, muscles, or nerves had been affected, or else they had been overlooked, which might easily occur. Turning to therapeutics, Mr. DeMerie, referring to the treatment he had adopted in his cases, which treatment had been very active, deprecated the fashion, now much in favour, of doing nothing; the cry being to cure, or attempt to cure various affections, *without* the remedies hitherto in use. This applied still more forcibly to the eyes. In such cases we had either to treat rheumatic ophthalmia, mostly connected with the joint affection, or the destructive conjunctival inflammation depending on actual contact with gonorrhœal pus. In both, especially in the latter, most active measures were required. The author had treated the two former successfully, but the cases had been very few, three of the former, and one only of the latter. He was confident that both the joint and eye complication, which had formed the subject of the paper, deserved much attention, and should be combated with the means which nature had placed in our hands.

Dr. DRYSDALE had seen several cases of what he was disposed to consider rheumatism dependent on gonorrhœal discharges. A case in a female, with urethral discharge had been shown him by Dr. Alfred Fournier, in the Hôtel Dieu in Paris, in October last, where the wrist joint was affected, and the fingers stiffened, and painful. Such cases were very obstinate, and although certainly rare, they appeared to him somehow connected with gonorrhœa.

Dr. TILBURY FOX suggested that the class of cases spoken of by Dr. De Merie might be examples of reflex action, and this would be corroborated if, as was stated by him, the disease usually affected the knee-joint, which would naturally suffer most when the urethra was irritated and inflamed, on that theory.

Mr. ADAMS said that Mr. Skey had once made the remark, that instead of this disease being called gonorrhœal rheumatism, it might with more propriety be called rheumatic gonorrhœa. Such affections of the joints, in his experience, were usually amenable to treatment and the prognosis was good in such cases. The true rheumatic affection of joints was, in his experience, never associated with the presence of pus in the joints.

Mr. BAKER BROWN, jun., said that he thought it must be indeed a difficult task to connect rheumatism of the joints in women with urethral or vaginal discharge, so universal were vaginal discharges in that sex.

Mr. WEEDEN COOKES said he was not ready to admit the specific character of the inflammation spoken of by Mr. De Merie. He thought it was only a coincidence, not a sequence, that was met with. Probably the derangement of the digestive organs by the needless exhibition of cubebs, &c., might often cause rheumatic disturbance. He objected then to the term gonorrhœal rheumatism.

Mr. POWER mentioned that he saw in the course of a year at least seventy cases of congenital purulent ophthalmia. He had made it his business to inquire in such cases what sort of a discharge the mothers were suffering from, and he was not able to say that in many cases there had been symptoms of gonorrhœa in the mothers. The best treatment for purulent ophthalmia was extreme attention to cleanliness, the eyes to be cleaned out every half hour, and a lotion of gr.  $\frac{1}{2}$  of arg. nit. ad  $\mathfrak{z}$ i. to be dropped into the eye frequently. Aconite was useful in rheumatic affections of the eye.

Mr. TEEVAN exemplified the use of the urethroscopé by an examination of two patients, the subjects of gleet. He pointed out the appearance of the inflamed portion of the urethra, and enlarged upon the advantages afforded by this instrument in the treatment of chronic urethritis.

It was moved, seconded, and carried unanimously, that a committee be formed for the purpose of investigating the best means of preventing venereal disease, and reporting thereon to the International Congress at Paris this year.

#### CITY AND COUNTY OF CORK MEDICAL PROTECTIVE ASSOCIATION.

The annual meeting of the members of this association was held in the lecture theatre of the Royal Cork Institution on the 5th of March.

Dr. HARVEY presided.

Amongst the other medical gentlemen present were:—E. R. Townsend, E. R. Townsend, jun.; W. Beamish; Johnson, Middleton; Johnson, Military Prison; S. Hobart, N. J. Hobart, G. J. Wycherley, D. C. O'Connor, T. S. Shinkwin, J. F. McEvers, W. T. Budds, S. O'Sullivan, R. Callaghan, Warren, Tuckey, Bantry; Moore, Looney, White, Resident Physician Cork Fever Hospital; T. Morrough, Kelly Spike Island; C. Armstrong, Holmes, P. Golding, W. C. Townsend, &c.

In opening the proceedings,

The Chairman said that it was not necessary for him to detain them by any lengthened observations. They were all aware of the character of their meetings; and he expected the character of that meeting would be in unison with them. The tenor of their business was not of a selfish or narrow nature at any time. Their anxiety was through the elevation of their profession to render service to the community at large by seeking, as far as they could, to improve the education of the medical man, and to improve his station and position in society, and thus render him a more efficient member of society than he otherwise would be, and better calculated for improving the military, naval, or other service in which he might be engaged.

The Secretary (Dr. Armstrong) then read the report, which is as follows:—

“Your committee's first meeting for the year just closed was held on the 7th of last April, when documents were read from Dr. J. S. Lee, hon. sec. of the Leeds Medical Registration Society on the subject of vaccination, but they arrived too late for action being taken on them. The melancholy death of Dr. Joseph Mackesy, of Waterford, having been alluded to, it was unanimously agreed that a resolution from this meeting be immediately sent to his father on the subject. Resolution—‘That we have heard with sincere regret of the unexpected death of Dr. Joseph Mackesy, of Waterford, and we would beg to offer to his respected father, our valued and long friend, the assurance of our heartfelt sympathy in his heavy affliction.’ Dr. Mackesy replied by sending his card, marked by deep mourning, on which was written—‘To express deep obligation and sincere thanks to the president and members of the County and City of Cork Medical Protective Association for their resolution of sympathy.’ On the 5th of May letters were read from Dr. Edgar, of Fermoy, Dr. Sandiford, of Castlemartyr, Dr. Madras, of Coachford, and Dr. Manly, West Bromwich, Staffordshire. Dr. Edgar says—‘I enclose my subscription and that of Dr. Blackquier for the current year, and assure you that the rules and exertions of the association meet my strongest approval.’ Dr. Sandiford writes—‘In enclosing my subscription, allow me to say how deeply I feel the benefits which the Association confers on the Profession, and as a dispensary medical officer, I am grateful for its exertions on our behalf.’ Dr. Madras alluded to the attempts being made to render the dispensary medical officers in some localities assistant-relieving officers, and asked for the copy of a letter addressed to the dispensary medical officers of Cork by the Poor-law Commissioners on the subject. Instructions were given that he be supplied with a copy of the letter. Dr. Manly writes—‘Will you kindly send me a copy of the last report of the Cork Medical Protective Association. I am secretary to our local society, and though we have done little hitherto, I am anxious to interest the members in matters not purely professional, but ethical and political.’ The copy of the report was forwarded to Dr. Manly. A special meeting of the Association at large was held on the 12th of May, at the instance of the President, who, in opening the proceedings, observed that the necessity for calling this meeting suggested itself to his mind on reading an article in a late number of the *Lancet*, on the constitution and powers of the Medical Reform Council of Canada, and the contrast its powers formed with the Medical Reform Council of this country, as well as from an announcement made in another number of the *Lancet*, that Sir George Grey would allow and assist Dr. Burrowes, President of the Medical Council, to bring in a bill this session, and arm the council with powers to accomplish what was so long and anxiously sought for—medical reform. The Chairman entered minutely into the subject, and maintained the idea that a sound preliminary and professional education was the grand bulwark against the schemes of quacks and impostors, by securing for the community and profession well educated men, and said that he brought this subject especially before the entire Association in order to ascertain if the Association deemed the occasion worthy of immediate action, and, if so, what that action should be. After much conversation, the Chairman

read a copy of a petition to Parliament, and of a memorial to Sir George Gray, whereupon it was resolved—that the petition and memorial be engrossed and printed, and that copies of the petition be sent to all the Associations in Ireland, and to at least one medical man in every Union, with a request that similar petitions be sent forward from the Associations and Unions. It was further arranged that influence be brought to bear on the Irish Parliamentary representatives to support the prayer of the petition. At the meeting of your Committee (a special one), held May 17th, two letters, dated 13th and 14th of May, were read from Dr. Johnston, and universal admiration expressed at the sensible, and practical observations contained in them, and a resolution passed unanimously—that this meeting fully entertains the sound views of Dr. Johnston, as recorded in his letters, and that, therefore, instead of petitioning Parliament, we first memorial the Medical Reform Council, and urge the necessity of their seeking powers to accomplish medical reform.

*"To the President and Members of the General Medical Council of The United Kingdom. The Memorial of the County and City of Cork Medical Protective Association,*

"RESPECTFULLY SHOWETH:—That your Memorialists look forward with deep interest to the measure which they understand is likely soon to be introduced into Parliament to amend the 'Medical Act' of 1858. That this Act must be looked upon as having, up to the present, fallen short of what was expected from it, in its two principle objects, viz. :—The protection of the public, and a really improved system of medical education. That with respect to the first of these objects, it appears to your memorialists that registration must continue to be all but nugatory, unless the knew legislation render it imperative on the Council to order, through duly authorized officers, the prosecution of all persons incurring the penalty specified in clause xl. of the Medical Act; or that which may be substituted for it. That the vastly more important object of securing a sound and adequate education for all candidates for medical and surgical qualifications, is not, in the apprehension of your memorialists, likely to be attained whilst the powers of the Council continue to be limited, as they are at present. To be enabled efficiently to provide for the country a body of properly qualified practitioners, it appears to memorialists that the Council should be empowered to prescribe and enforce such educational regulations as may be found requisite for the attainment of that important object. That no education, memorialists respectfully submit, can be considered sound and adequate, which does not include as preliminary to entering on medical studies, properly so called, such a course both literary and scientific, as will enable the student effectively to master the varied subjects of professional study with which he will have to grapple, and afterwards, to take such a position amongst men of general information, as will be calculated to maintain for medical science the estimation in which it is desirable, for the good of mankind it should be held. That the course for a degree in Arts in the different Universities should, in the opinion of your memorialists, be preliminary to that for a degree in Medicine, and that a course of education, embodying both classical studies and the various branches of physical science, should be indispensable before entrance on medical and surgical education of whatsoever character. Wherefore, your memorialists would respectfully suggest the expediency of the Council seeking for such a modification of clause xli. of the Medical Act, as will secure the prosecution of offenders against its provisions. But especially of seeking for the power to establish a uniform curriculum of studies, preliminary and professional, which shall be binding on all the educational bodies of the country.—And your Memorialists, &c."

Copies of the memorial were sent to Dr. Burrowes, Dr. Mackesy, Dr. Quinan, Dr. Aquilla Smith, Mr. Hargrave, Dr. Stokes, Sir D. Corrigan, Dr. Apjohn, and the editors of the *Lancet*, *Medical Times*, and *British Medical Journal*. Dr. Burrowes replies thus:—

"General Council of Medical Education Registration of the Kingdom,

"Soho-square, London, W., 2nd June, 1866.

"SIR—I am desired by the President of the General Medical Council to acknowledge the receipt of your letter of the 31st ult., and to inform you that the memorial of the County and City of Cork Medical Protective Association transmitted by you reached him, but not until Monday the 22nd ult., when the Council had already been sitting four days, and had a large amount of business already before it, so that the memorial

could not, in justice to other communications, take precedence of them. The memorial was duly submitted to the Council on the 29th ult., and ordered to be entered on its minutes for that day. The subject of it had already and for a considerable time engaged the consideration of the Council.—I am, sir, your obedient servant,

FRANCIS HAWKINS, Regr.

"Charles Armstrong, Esq., M.D., hon. sec."

Mr. Hargrave says—

"London General Council of Medical Education and Registration of the United Kingdom,

"May 22, 1866.

"DEAR DR. ARMSTRONG—I have received your memorial, and wish to inform you that we are giving particular attention to the important question of education. As to the preliminary arts' education, however, you may be disappointed as to the working of the bill. I must say that this Council have been giving every attention, and the failure does not show any neglect of it. If you have read the strictures on the Indian Civil Service examination just concluded, there is a melancholy statement of candidates' great deficiency in English language. You may depend on it I will pay every attention to your letter, the memorial, and its suggestions.—Yours sincerely, dear doctor,

"WILLIAM HARGRAVE."

A special meeting of your Committee was held on the 18th of June, in consequence of receiving the annexed requisition:—

"TO THE SECRETARY OF THE CORK MEDICAL PROTECTIVE ASSOCIATION.

"SIR,—We, the undersigned members of the Cork Medical Protective Association, beg you will convene a special meeting of the committee, at the earliest possible period, to take into consideration the recent occurrence at the Cork Union Workhouse."

(Signed)

"THOMAS GREGG, M.D.

"E. R. TOWNSEND, Jun., M.D.

"N. J. HOBART, M.D.

"D. C. O'CONNOR, M.D.

"JAMES J. CURTIS.

"June 15th, 1866."

A meeting was accordingly held, and numerous attended, and after much warm discussion, resolved by acclamation:—

"That while we consider the members of our profession might confer great advantage on the public medical institutions by taking part in their general administration, we are nevertheless of opinion that any interference whatever of a professional nature by such members cannot fail to be productive of evil to the patients, and to bring discredit on the profession." It was further arranged that this resolution be published in the local papers, and THE MEDICAL PRESS AND CIRCULAR. On the 4th of August a letter was read from Dr. Johnston:—

[COPY].

"1, Park View Terrace, July 27.

"MY DEAR DR. ARMSTRONG,—I happened to be in court to-day, when the case of *Foley v. Poole* was tried, an instance, as you are no doubt aware, of a pauper patient endeavouring to obtain damages from the medical officer of the Ardmore Dispensary, for malpractices and neglect. This attempt, I am happy to say, was a complete failure, and verdict was given in favour of Dr. Poole, without a witness being called for the defence, Judge Fitzgerald stating that Dr. Poole left the court without the slightest stain on his professional character. I had no idea that the practice so prevalent, I regret to say, of late, in England, of endeavouring to extort money from practitioners in medicine and surgery for alleged malpractice and neglect, had extended to Ireland. This gross, and fortunately unsuccessful attempt has proved that we are liable to these unprincipled attacks here as well as elsewhere. I think this is a case for the Cork Medical Protective Association to take cognizance of, and that we should meet on an early day for the purpose of expressing our sympathy for Dr. Poole, under this unwarrantable attack on his professional character, and the members of the profession, not only in Cork, but throughout Ireland, should, by subscription, endeavour to compensate him for the pecuniary loss necessarily sustained in conducting his successful defence. It appears to me that this is one of these cases which eminently deserve the sympathy of every member of our profession. None of us know when our time for selection for these iniquitous persecutions—under the name of prosecutions—may occur, but, by uniting now in defence of our outraged confrère, we take the most effectual means of deterring unprincipled adventurers from initiating similar proceedings

against members of our profession. I shall be very happy to contribute a guinea to a fund for this purpose.—Believe me to remain, yours very sincerely,  
JOHN W. JOHNSTON."

"A meeting was shortly after held, at which strong expressions were used condemnatory of the action, and resolutions of a similar character, as well as one calling on the profession of Ireland to defray the expenses of the action, which were unanimously passed; circulars also were distributed. These resolutions were published in the Cork papers, *Waterford Mail*, and the *THE MEDICAL PRESS AND CIRCULAR*. The result proved successful, as evidenced by many satisfactory replies, several of which appeared in different numbers of the *Dublin Press and Circular*. On the 2nd of February, a special meeting was held, at which it was unanimously resolved—"That our Secretary be requested to convey to William P. O'Brien, Esq., Poor-law Inspector, our deep regret at the severance of his official connection with this district—a connection which, whilst it contributed in no small degree to promote the interests of the union, was also found not to be incompatible with the rights and privileges of the medical profession. That we earnestly hope, and believe, that Mr. William P. O'Brien's administrative talents, his intimate acquaintance with the details of the Poor-law Acts, and his uniform urbanity, will ere long secure for him an appropriate recognition in a higher sphere of official usefulness.—Signed, JOSHUA R. HARVEY, M.D., Chairman; CHARLES ARMSTRONG, M.D., Honorary Secretary."—Reply—"Malahide, Dublin, 9th Feb., 1867. My dear Dr. Armstrong—Do me the favour to convey to your worthy President (Dr. Harvey) and the other members of the Cork Medical Protective Association, my grateful acknowledgment of the complimentary resolution unanimously adopted by them, in my regard, at their meeting of the 2nd instant, and the value of which has been greatly enhanced, in my estimation, by the terms in which it has been communicated to me by you. Few are in so favourable a situation to judge and appreciate the sacrifices and labours entailed on the members of your profession charged with the care of the sick poor in this country, as those occupying the position I have the honour to fill in the public service, &c.; none can testify more readily or warmly than I do to the great patience, devotion, and attention with which, as a general rule, they have acquitted themselves of their important and responsible trust. During my lengthened connection with the South, I enjoyed the privilege of an intimate and extensive acquaintance amongst the medical gentlemen practising both in the city and throughout the county of Cork; and now that an intercourse which, while it lasted, was a source of as much advantage as satisfaction to me, has been interrupted by my removal to a remote sphere of duty, it is peculiarly and deeply gratifying to me to receive the flattering assurances their resolution conveys, that I carry with me and will still retain the good wishes and esteem of a public body, whose favourable opinion and approbation I so highly prize.—Believe me, dear Dr. Armstrong, ever faithfully yours, W. P. O'BRIEN." The important subject of establishing a Cork branch of the British Medical Association was brought before your committee by Dr. Johnston, and a sub-committee, formed for the purpose of ascertaining the ideas of the profession, with a view of carrying into effect this desirable object. The annual reports of the Association for the last ten years are suggestive and worth perusal, showing an amount of labour that has already accomplished substantial good, while much remains still to be done. For instance, the paramount question of 'Medical Reform,' embracing a sound preliminary and subsequent education, as well as the suppression of quacks and impostors; the inadequate pay of poor-law medical officers, and the fact that, after long responsible and laborious services, in discharge of which their health is often broken down, they receive no retiring pension, thus forming a striking contrast with other branches of the Civil Service. Again, the strange injustice so long pursued to our brethren of the Army and Navy, for a redress of whose grievances this association has long laboured, as well as the fact many times pressed on the authorities—namely, the important benefit rendered to the ends of public justice by skilled medical evidence given in courts of laws, the remuneration awarded being an outrage to which no other profession would for a moment submit. Long experience proves that a redress of these grievances can only be obtained by the continued exertions of medical men themselves, the result of which cannot be doubtful, founded as these exertions are on justice, reason, and conscience. 'In omni publico munere id solum spectare debemus quid justitia postulet, ratio praecepta conscientia proponat.'

Dr. E. R. Townsend said in the absence of Dr. Mackesy, who had devoted his time, his talents, and unwearied assiduity to the working out of the object of their association, he would move the first resolution. A great number of resolutions of much importance were to be proposed, which would require to be elucidated by the proposers, so that he would not take up their time by lengthened observations; he would merely move that the report as drawn up by their secretary, with his usual perspicuity, clearness of style, and happy classical allusions be adopted (applause).

Dr. Johnston, Midleton, seconded the resolution, which passed *nem con*.

Dr. O'Connor proposed the next resolution, which was:—"That, in the opinion of this meeting, the 'Medical Act's Amendment Bill,' shortly to be introduced into Parliament, is seriously defective, inasmuch as it makes no provision for an improved and superior system of medical education, preliminary and professional, or for the official prosecution of unregistered practitioners, or persons illegally assuming medical titles." It would astonish any one, he said, to think that the Medical Council, which was supposed to have been selected from their profession for the purpose of its advancement and progress, would neglect the important points and matters referred to in the resolution. It was impossible for their profession to hold the standing they claimed for it unless the education of the medical men was upon an equality with the other professions (hear, hear). It was the lot of doctors, whether in the army, navy, or in private society, to be introduced to men of the highest station, intellect, and the most refined manners; and to fit him for such society, their education should be equal to that of accomplished gentlemen. The speaker then enlarged upon the subject, and concluded by proposing the resolution amid applause.

Dr. Beamish seconded the resolution, which passed unanimously.

Dr. W. C. Townsend, in proposing the next resolution—"That it appears to this meeting that the several clauses of the Sanitary Act of 1866, applicable to Ireland, are sufficient to enable the local authorities to establish and carry out an effective system of supervision of the public health"—said he regretted very much that his friend Dr. Tanner was unable to be present, as he was to have proposed the resolution, and no doubt was quite prepared to speak on the subject. It must be very gratifying to them to find that Government had taken up this very important branch. The good effects of it were already manifesting themselves in this city, and their worthy Mayor had exerted himself unceasingly in carrying out the provisions of the late act. It was to be hoped that in other parts of the country, where such power was vested in poor-law guardians and other bodies, it would be as stringently and as fully carried out (hear, hear).

Dr. G. Wycherley seconded the resolution, which was adopted.

Dr. O'Flynn, jun., proposed—"That we cannot but express our regret that, in the late enactment which granted a retiring pension to superannuated poor-law functionaries, the medical officers should have been excluded. Inadequately paid as they are, even at the present maximum salary, hard worked, and their labours to the poor not limited to any hour of the day or night, we consider the worn-out medical men eminently entitled to a retiring allowance in their old age, and we trust that justice will be speedily done to them in this respect." He said in considering that resolution, one of the first questions to be asked was, if this superannuation allowance were granted, how was it to be paid. If out of the rates, it would encounter an amount of opposition that might prove fatal to it from parties who, perhaps, otherwise would be in favour of it. But there was no such intention on the part of those who advocated the movement and admitted the justice of the claims of those whom it concerned. It was proposed to assimilate the case in this respect to that of England, where, since 1846, half the poor-law medical responsibilities are paid out of the consolidated fund. It was to be hoped this would be extended to Ireland, and unless Ireland was to be always exceptionally treated in this as in political matters, the arrangement would be extended to this country.

Dr. Goulding seconded the resolution, which was carried.

Dr. Morrogh, after some brief but terse remarks, proposed the fifth resolution—"That, with our present limited knowledge of the army and navy medical warrants of 1867, one of which only has as yet been promulgated, and which falls short in some respects of what was looked for, we still hope that

when fully brought into operation they may be such as to increase the efficiency of both services."

Dr. M. Hobart seconded the resolution, and in doing so delivered a very practical speech, which was loudly applauded.

Dr. S. Hobart proposed—"That the medical profession is the only body whose services Insurance Companies obtain for less than their legitimate remuneration. This anomaly is the more striking, as those companies are mainly dependant on their medical advisers for the realization of their profits, and it only requires unanimity and self-respect on the part of the profession to do it away."

Dr. M'Evers seconded the resolution, which passed.

Dr. Cremen, in the absence of Dr. Shinkwin, proposed—"That the remonstrances so often addressed to the authorities in reference to the skilled medical evidence given in Courts of Justice, being still unattended to, we consider a strong necessity rests on all the Associations for continual agitation on this subject." It certainly, he said, was a monstrous grievance to think that an attorney could *subpœna* a physician to attend a court of justice to give evidence for a client, and was at liberty not to pay him for his attendance. A physician was to neglect his important public duties and his private practice, to attend and give evidence without being recompensed for his loss of time.

The resolution was seconded by Dr. Budd, and passed.

Dr. R. Callaghan proposed and Dr. O'Sullivan seconded—"That we have much pleasure in again recognizing and acknowledging the able advocacy of the press, on all occasions where the interests of the profession have been involved."

A vote of thanks was passed to the chairman, and the meeting adjourned.

## Correspondence.

SIR CHARES COOTE, BART.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the *Northern Whig* of the 4th inst., there is a mistake as to the identity of the Sir Charles Coote who was recently fined in London for assaulting the Station-Master of the Charing-Cross Hotel. The paragraph in the *Whig* runs as follows:—"The frolicsome baronet in question entered as a medical student at the Royal College of Surgeons in Ireland about sixteen months ago, having duly passed the preliminary examination in Arts."

As the above statement, if uncontradicted, might seriously interfere with the professional and other prospects of my young relative and apprentice, I immediately wrote the following letter to the Editor of the *Northern Whig*, which he published in his paper of this morning, and which I shall feel obliged by your inserting in the ensuing number of the MEDICAL PRESS AND CIRCULAR.—Your obedient servant,

B. WILLS RICHARDSON.

March 7th, 1867.

"MISTAKEN IDENTITY.

"TO THE EDITOR OF THE NORTHERN WHIG.

"SIR,—Permit me to correct an error which appears in your impression of the 4th inst., regarding the identity of the Sir Charles Coote who was fined for an assault in London within the last few days.

"The Sir Charles Coote alluded to in your paper happens to be my apprentice—is not twenty years of age—has never been out of Ireland, and, consequently cannot be the 'frolicsome baronet' who committed the assault in question.—I have the honour to remain your very obedient servant,

"B. WILLS RICHARDSON, F.R.C.S.I."

"2, North Frederick-street, Dublin,

March 5th, 1867."

(On referring to Burke's Peerage and Baronetage, it will be seen, that there are two Sir Charles Coote's, both of course baronets, one Sir Charles Algernon Coote, the baronet at present studying medicine, the other Sir Charles Henry Coote of Ballyfin House, Mountrath, Queen's County.—B. W. R.)

## POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

12 Royal Terrace, Weymouth, 5th March, 1867.

SIR,—I shall feel obliged by your inserting the annexed letter addressed to the President of the Poor-Law Board. I congratulate the Metropolitan Poor-Law Medical Officers on the success they are likely to achieve, and I trust the time will come when my provincial brethren will be equally fortunate.—I am, &c.,

RICHARD GRIFFIN.

12 Royal Terrace, Weymouth, 4th March, 1867.

SIR,—Having already furnished you with a large mass of evidence on the medical treatment of the poor of England and Wales will, I trust, plead my apology for troubling you with the remarks I desire to make on your Metropolitan Poor Bill.

By the present law, one half the salaries of the medical officers, and the cost of medicines, when found by the Guardians, are a charge upon the Parliamentary Grant, and the other half on the common fund of the union; but by your Bill, as I understand it, the entire cost for the asylums will be defrayed by contributions from the Unions and Parishes forming the District, and in the case of the Dispensaries, from the common fund of each Union, and thus the consolidated fund will be entirely freed from the charge. Is this your intention?

In Clause 43 of the Bill you state, "the Guardians of each Union shall provide proper medicines, and the same shall be dispensed and furnished to such of the poor in receipt of relief as require the same." Now, it appears to me that, by the wording of the clause, no person will be entitled to medical assistance unless already in receipt of relief, and thus, in future, at least one-third of all the sick poor of the metropolis will be deprived of medical relief at the cost of the rates. Although I grant that many now receive relief both in England and Ireland who ought not to have it, still, the line confining medical assistance to paupers only is far too stringent. See pamphlet entitled "Evidence on Poor-Law Medical Relief," pages 6 to 7.

The question of who shall find the drugs for the poor is one of vital importance. I think they should be furnished by the Poor-Law Board, as the only means of insuring good drugs. This course is followed by the Army and Navy. On reference to pamphlet entitled "Evidence," pages 89 to 97, this subject is fully entered into, and in the remarks at page 92, last paragraph, the objections to the Guardians finding drugs are specially pointed out. The Parliamentary grant would be a convenient source from which the cost of the drugs might be defrayed.

The whole of the medical treatment of the poor, both in asylums and dispensaries, should be placed under the charge of the managers of each asylum district, in fact, the dispensaries might be made appendages to the asylums.—I have the honour to be, &c.,

RICHARD GRIFFIN.

The Right Honourable the President  
of the Poor-Law Board.

## COPY OF MEMORIAL

To the Right Honourable Lord Naas, Secretary of State for Ireland.

BANBRIDGE, FEBRUARY, 22nd, 1867.

MY LORD,—I take the liberty of drawing your attention to a case in which I feel myself done injustice to by Dr. George Tyrrell, Coroner for the Southern Division of County Down; and were I not fully conscious of the justice of my case, I would not now trouble you with it, knowing that you must be greatly engaged with Parliamentary and other duties. I will be brief as possible. During last summer I attended an old man named Andrew Campbell, who had received a wound in

the back of his hand which was inflicted by his brother-in-law Patrick Dimond. After some time the hand and arm were attacked with erysipelas which proved very tedious. As he had only four shillings per week out of the Milltown Relief Fund, to support him and his wife, he was recommended to go into the Infirmary of the Banbridge Union Workhouse, in order that he might get proper nourishment. Of the advantages of the Infirmary he availed himself, and in course of a little time died. He was given out to his friends for interment, when a report got up that the wound was the cause of his death; and previous to his being buried, an inquest was held on him on 6th September, 1866, at which Dr. Malcomson, the surgeon of the Union and I were examined; and I may state to you that I was the leading evidence, for which I would refer you to Mr. Robert Erine, woollen draper, the Foreman of the Jury. When Acting-Corstable James M'Guinness came for me, I was going out to the country, and was therefore obliged to go on behalf of the Crown, wait, and be examined. For my loss of time and evidence, Dr. Tyrrell informs me he cannot give me anything. He says he is only empowered to give £1 1s., and that he has given it to Dr. Malcomson. Now, I think I have, according to act of Parliament, a right to my fee, as a civil practitioner; and I am also of opinion when an officer of a public institution receives a fee, and a civil practitioner is set aside, it savours something of favouritism. Trusting your Lordship will give this case your consideration, I have the honour to remain your obedient servant,

R. P. BROWN M'CLELLAND, M.D.

DUBLIN CASTLE, 1st March, 1867.

SIR,—In reply to your letter of the 22nd ultimo, requesting payment for having attended as a witness at a Coroner's inquest on the body of Andrew Campbell, I am directed by the Lord Lieutenant to inform you that this is not a matter in which his Excellency has any power to interfere.—I am, sir, your obedient servant,

NAAS.

R. B. M'Clelland, Esq., M.D., Banbridge.

## OBITUARY NOTICE.

### THE LATE PROFESSOR GOODSIR.

THIS distinguished anatomist died last Wednesday at Wardie, near Edinburgh. He had, as is generally known, been for some years an invalid, but had only given up his active duties at the University within a very brief period. On Friday evening at the Royal College of Physicians of London, Dr. Andrew Clarke, in his first Croonian Lecture, of which we shall next week give a report, paid a feeling tribute to "his old master, John Taylor Goodsir," and pointed out how completely the just deceased pathologist had forestalled Virchow. He obtained the chair of anatomy in the University of Edinburgh in 1846, succeeding Dr. Monro. He had previously filled the office of Demonstrator in the University, as well as that of Conservator to the Museum of the Edinburgh College of Surgeons. As an original enquirer his reputation has long been European, and as a teacher his memory is enshrined in the hearts of many grateful followers in his footsteps. He died unmarried in his fifty-third year, an early age for one to have passed away from us, whose teachings have moulded the thoughts of many of the first living physicians and surgeons in Europe. It cannot but be a source of regret that his eager pursuit of science and feeble frame did not leave him time to collect his many scattered labours. Enough, however, remains to vindicate his claim to the highest distinction, and to prove that many of the so-called discoveries of Germany are but the reflected rays of his luminous genius.

## Examination Papers.

### KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Quarterly Examination for Licenses in Medicine, February, 1867.  
(Second Day.)

(Continued from page 230).

#### PRACTICE OF MEDICINE.—DR. GORDON.

1. What are the symptoms and physical signs of tuberculization of the bronchial glands?
2. State the causes, symptoms, and principles of treatment of pulmonary apoplexy.
3. What are the symptoms produced by the passage of a gall stone; and how would you treat them?
4. Give the symptoms, effects, and treatment of whooping cough.
5. What is the state of the blood in rheumatic fever?  
The candidates also underwent a *viva voce* examination of five rounds of questions from each examiner.

### QUARTERLY EXAMINATION FOR LICENSES IN MIDWIFERY—FEB., 1867.

#### MIDWIFERY—DR. JOHNSTON.

1. What are the diameters of the brim, cavity, and outlet of the female pelvis?
2. What are the different positions the foetal head presents at the brim?
3. Describe the passage of the foetus through the pelvis, when the head presents in the first position (of Nægelè) at the brim?
4. What are the dangers most commonly to be guarded against during labour?
5. At what period after delivery does the secretion of milk usually take place, and what are the symptoms attendant thereon?

#### MIDWIFERY—DR. RINGLAND.

1. State the ordinary management of a patient in the third stage of labour?
2. Under what circumstances does the spontaneous evolution of the foetus take place, and describe the process?
3. Specify the form of labour most hazardous to the mother alone; that to the child alone; and that to both mother and child?
4. Mention all the varieties of complex labour.
5. State the several stethoscopic symptoms of pregnancy, mentioning the value of each respectively, the earliest period at which each becomes available, and the sources of fallacy connected with each.

### UNIVERSITY OF DUBLIN—TRINITY COLLEGE.

#### EXAMINATION FOR SURGICAL DEGREES.

HILARY, 1867.

Dr. ADAMS.

1. Give the symptoms of caries of the vertebræ, arranged accordingly as the disease exists in the cervical, dorsal, and lumbar vertebræ.
2. Give the symptoms of the disease which proceed from spinal caries, and consequent symptomatic abscess.
3. Give also those produced by irritation extending from the bones to the membranes of the spinal marrow, and to the medulla spinalis itself.
4. Give the prognosis which should be formed as to the probable results to be expected from the disease, as it exists in the cervical, dorsal, and lumbar regions of the spine, respectively.
5. Describe a case of dry gangrene of the foot, called "Pott's gangrene."
6. Give Baron Dupuytren's opinion as to the gangrena senilis of Pott, and its cause.
7. Give the treatment of the disease recommended by Mr. Pott.
8. Give the treatment also recommended by Baron Dupuytren.
9. Describe a case of ranula.
10. The surgical treatment of this disease?

## SURGERY—PROFESSOR R. W. SMITH.

1. Describe a well-marked case of pulsating bronchocele.
2. Mention the local conditions that retard or prevent the union of fractures.
3. What constitutional causes produce the same effect?
4. Enumerate the methods of treating disunited fractures.
5. Causes, symptoms, and treatment of traumatic hernia cerebri?
6. Give the pathology of congenital hernia cerebri; mention the diagnostic characters of the tumour.
7. With what morbid states of the eye is "tremulous iris" connected?
8. Forms of inflammation and abscess that occur in the parotid space?
9. Characters of a benign nasal polypus?
10. Mention the forms of retro-pharyngeal abscesses; what symptoms and dangers attend them?

## DESCRIPTIVE AND SURGICAL ANATOMY.

## Professor M'DOWEL.

1. Contrast the vascular supply of the scalp with that of the integument elsewhere; and mention how this influences reparative action after injury.
2. Enumerate the bony connexions of the superior maxilla.
3. What arteries are necessarily divided, and what are liable to injury, in the operation for the removal of half of the lower jaw?
4. Describe anatomically the several steps of the operation for ablation of the tongue after Symes' method.
5. Mention any cases you are acquainted with of ligature of the internal iliac artery, and describe the operation.
6. Give the attachments, and describe the relations of the anterior annular ligament of the carpus.
7. For what disease has the division of this ligament been recommended, and by what surgeon?
8. What arterial anomalies may give rise to danger in the operation for strangulated femoral hernia?
9. Up to what age is disjunction of the lower epiphysis of the femur possible?

## EXAMINATION FOR MEDICAL DEGREES.

HILARY, 1867.

## PRACTICE OF MEDICINE.—DR. STOKES.

1. Compare the macule in purpura and in typhus fever, as to character, locality, and history.
2. How would your prognosis be influenced in a case of typhus by the period of appearance of the macule?
3. What is meant by Febris Senilis? In what does it resemble the Febris Infantum? Give the prognosis, and the most frequent complication.
4. How far does the history of epidemics of cholera favour the doctrine that it is a contagious disease?
5. At what period do the symptoms of uræmic poisoning appear in cholera? Describe these symptoms.
6. How would you treat suppression of urine in cholera?
7. What is the general result in the treatment of cholera by transfusion of saline solutions?
8. Describe the disease termed Exophthalmic Goitre or Bronchocele; is it capable of cure? State whether it is originally an organic or a functional disease.
9. What are the symptoms of the crowing disease of infants (Laryngismus Stridulus)? Give its pathology, prognosis, and treatment.
10. Explain the occurrence of aphonia, stridor, and sudden amaurosis of a single eye in aneurisms of the thoracic aorta and in disease of the heart.

## PROFESSOR BANKS.

1. Describe the eruption in the regular form of morbilli, and the varieties in the appearance of the rash.
2. What are the most formidable complications of morbilli?
3. Enumerate the most frequent sequelæ.
4. Contrast morbilli and scarlatina in the stage of eruption?
5. What are the parts of the muscular system which may be the seat of paralysis in typhus fever, and their relative importance?
6. Enumerate the diseases which may occur as sequelæ of pertussis.
7. What are the principal points to be taken into considera-

tion in forming an opinion as to the probable termination of pneumonia?

8. How would you treat suffocative catarrh?
9. Describe a case of gangrene of the lung, and state how you would treat it.
10. What is the pulmonary disease most likely to be mistaken for gangrene of the lung?

## DR. AQUILLA SMITH.

1. What is Cusso, its therapeutic use, dose, and mode of administration?
2. Give the botanical name and characteristic distinctions of Common Hemlock, the characteristic test of its active principle, the preparations in the British Pharmacopœia, and the part of the plant from which each is made.
3. Enumerate the reputed antispasmodics in the Animal and Vegetable Kingdoms, which are in the Materia Medica. Give a description of one in each division, stating its dose, and mode of administration.
4. State the quantity of lime in one fluid ounce of "Liquor Calcis Saccharatus," and also the quantity in one fluid ounce of "Liquor Calcis."
5. What are the colour and appearance of the following tinctures when diluted with an equal bulk of distilled water:—"Tinctura Asafetida," "Tinctura Benzoini Composita," "Tinctura Gentianæ Composita," and "Tinctura Cannabis Indicæ?"
6. Name the drugs which cause dilatation of the pupil, and those which cause contraction of the pupil, when applied to the eye, or administered internally.
7. State the composition of "Mistura Creasoti," and of "Pulvis Rhei Compositus."
8. In what respect does "Extractum Ergotæ Liquidum" differ from "Urgota?"
9. Name the preparations of Belladonna in the British Pharmacopœia, the part of the plant from which each preparation is made, and their respective doses and modes of administration.
10. Write a prescription in Latin, without abbreviations, for a tonic-aperient mixture.

## CHEMISTRY.—DR. APJOHN.

1. Write the formula of crystallized phosphoric acid in its tribasic condition; explain also how the acidum phosphoricum dilutum of the Pharmacopœia is made, how its strength is determined, and how it is tested for nitric and for monobasic phosphoric acid.
2. Enumerate the different phosphates of which mention is made in the Pharmacopœia; and explain the process by which the calcis phosphus præcipitata is made; mention also any experiment by which it may be distinguished from alumina.
3. How is bismuthum album made? what is the formula which represents its composition? and how would you show that nitric acid is a constituent of it, and that it does not include either lead or arsenic?
4. What is the formula of potassæ permanganas? how is it made? and what is the reaction exerted by it on green vitriol in the presence of hydrochloric acid?
5. Give in symbols the composition of crystallized borax; and explain how it is made in Tuscany from boracic acid, and how this acid may be separated from it.
6. When calx chlorata is dropped into muriatic acid, chlorine is developed; give the theory of this reaction, and describe the volumetric process by which the exact amount of the chlorine disengaged may be determined volumetrically.
7. What is Schneider's process for separating arsenious acid from organic matter? State also how, when the separation is accomplished, the amount of the arsenic is determined by him.
8. How is the protein of Mulder made? and what evidence is obtained in the course of its preparation that unoxidized sulphur is an element of the proteinic compounds?
9. Mention the colour-tests for morphia, quinia, and cinchonia; and explain how you would ascertain the amount of each of these alkaloids in a mixed solution of their hydrochlorates.
10. Enumerate the various tests for albumen in solution, and state how you would distinguish coagulated albumen from fibrin.

## ANATOMY AND PHYSIOLOGY.—PROFESSOR M'DOWEL.

1. Trace the course and distribution of the cerebral branches of the internal carotid artery.
2. Describe the fornix cerebri, and mention its connexions.

3. What phenomena would follow a section of the trunk of the fifth cerebral nerve?

4. Describe the scaleni muscles; give their attachments, and assign their actions.

5. What opinions are held as to the functions of Peyer's glands?

6. What veins have no valves? Indicate the position of the valves in the principal veins of the lower extremity.

7. What phenomena would you expect to follow a transverse section of one half of the spinal cord?

8. Describe the iris; what nerves are distributed to it?

9. Describe the tricuspid valve, and explain the mechanism of its safety-valve function.

10. Give a brief account of the arrangement of the minute vessels of the liver.

## Medical News.

### LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR FEBRUARY, 1867:—

Sandham, Wm. Sale, Cork, L.R.C.P.Edin., 1866. L.R.C.S.Edin., 1866.  
 Ratton, James Joseph, Louis, Dublin, M.D.Q.U.I., 1865. Mastr. Surg., Q.U.I., 1866.  
 Cooper, Robert Heath, Enniskillen. L. Apoth. Hall, Dub., 1866.  
 Lynam, Terence, Strokestown, Co. Roscommon, L.R.C.P.Edin. 1867; L.R.C.S.Edin. 1867.  
 White, James, Kilkenny, L. Apoth. Hall, Dub. 1866.  
 McCaw, John Dvsart, Portlengone, Co. Antrim, L.R.C.S.Edin. 1866; L.R.C.P.Edin. 1867.  
 Craig, Richard Manifold, Dublin, L.R.C.S.I. 1866; L. 1867, and L. Midwif. 1867, Q.C.P.I.  
 Griffin, George Leake, Dublin, L.R.C.S.I. 1866; L. 1867 and L. in Midwif. 1867, K.Q.C.P.I.  
 Grealy Francis, Galway, M.R.C.E. 1865; L.R.C.P.Edin. 1866.  
 Hudson, Robert, Co. Kerry, L. in Med. Univ. Dub. 1865; L. 1865, and L. Midwif. 1866, R.C.S.I.  
 Conolly, James, Galway, M.D.Q. Univ. Irel. 1866; L.F.P.S.Glas. 1867.  
 McCnaghy, Charles, Convooy, Co. Donegal, L.R.C.S.I. 1866.

**CHOLERA AT PORT GLASGOW.**—It may be remembered that at the beginning of the year a sudden outbreak of cholera, resulting in a good many deaths, took place at Port Glasgow. After the lapse of nearly two months the disease has again appeared within the last few days, and four deaths have occurred, the victims being three young persons and an adult. The medical officers report a considerable prevalence of choleraic diarrhoea. It would seem that in a sanitary point of view certain portions of the town are still in an unsatisfactory state.—*Times*.

**BOARD OF SUPERINTENDANCE OF CITY OF DUBLIN HOSPITALS.**—His Excellency the Lord Lieutenant has appointed Christopher Fleming, Esq., M.D., Member of the Board of Superintendance of the City of Dublin Hospitals, in place of the late Dr. Hutton.

**WOUNDED SOLDIERS IN BATTLE.**—The Prussian papers mention a new plan for the care of the wounded on a field of battle, which was tried during the war, and has now been definitely adopted. Every surgeon is to be provided with a pocket book containing a pencil and a number of labels (like those sold for luggage apparently) with a string at one end. After attending to a wounded man, the surgeon writes on one of these labels the name of the wound and what he has done to it, signs the label, and ties it to the wounded man's button hole. Thus the man can be carried at once by the hospital attendants to the proper place, and the surgeon to whom he is brought can learn in a moment the state of his wound, and proceed to dress it.

**THE ATTEMPTED MURDER OF DR. PRITCHARD AT ABERAVON.**—Captain Jones was brought before the Neath bench of magistrates, charged with having on Monday shot at Dr. Pritchard with intent to murder him. The complainant is a surgeon practising at Aberavon, and whilst returning home on Friday from the Margam Tin Works, of which he is part owner, the prisoner gave him a letter, telling him it was to demand money, and that he would wait till three o'clock for the prosecutor to consider it. The prosecutor told him he owed him no money, but if he appealed to him by way of charity he would give him some. On Saturday the complainant again saw the prisoner, apparently lying in wait, and avoided him. On the day in question the prosecutor was proceeding along a narrow lane when he saw the prisoner approaching him. The prosecutor asked him what he wanted? when he replied "I

want my money or your life," at the same time producing a pistol. The prosecutor tried to avoid him, but soon felt that he was wounded on the right side of the temple, but not dangerously. The prisoner said when taken into custody, that he wanted to see the prosecutor on his way home, and that he fired because Dr. Pritchard tried to ride him down. The magistrates committed the prisoner on the charge of shooting with intent to murder.

**HARVEIAN SOCIETY OF LONDON.**—Committee for the Prevention of Venereal Diseases:—Dr. J. E. Pollock, president; Dr. Broadbent, Dr. Chapman, Dr. Charles Drysdale, Dr. Tilbury Fox, Dr. Maudsley, Dr. Meredyth, Dr. Tyler Smyth, Dr. Menzies, Dr. Semple, Mr. Weeden Cooke, Mr. Curgenvin, Mr. Gascoven, Mr. E. Hart, Mr. J. Lane, Mr. Sedgwick, Mr. Teevan, Mr. H. Thompson, with whom will be associated Mr. Acton, Mr. Holmes Coote, Mr. R. W. Dunn, and Dr. Victor Bazire. Objects—To investigate the extent of the spread of the contagious diseases commonly called Venereal Diseases among the civil population of this country; to discuss the best means for preventing that widely-extended evil, and to report thereupon to the International Congress to be held this year in Paris. "Something more than the Contagious Diseases Act of 1866 is necessary, if the community at large, and not only our troops, are to be benefited."—From Dr. Jenner's address at the Epidemiological Society, as president for the session 1866-7. Communications and suggestions to be sent to Dr. Charles Drysdale, 99, Southampton-row, W.C., London; J. B. Curgenvin, Esq., 11, Craven-hill Gardens, W., honorary secretaries.

**SCURVY IN THE MERCANTILE MARINE SERVICE.**—On Wednesday afternoon an adjourned inquiry was held at the Bee-hive public-house, Greenwich, before Mr. C. J. Carttar, coroner, into the circumstances attending the death of John Ashley, aged 27, a seaman on board the ship "Timour," belonging to Messrs. Ashton (of Manchester) and Rathbone (of Liverpool), who, with eight other seamen belonging to the same vessel, were admitted on board the "Dreadnought" Hospital ship suffering from scurvy contracted while on the homeward voyage from Calcutta to London. At the conclusion of the evidence, which was of considerable length, the coroner said he could not see why the supply of lime-juice should not be made as arbitrary as the requirement of vaccination in relation to small-pox. An Act of Parliament was urgently required on the subject, and ought to be taken up by the Government or some member of the House of Commons. Had it been proved in the present case that deceased's death had arisen from the bad quality of the lime-juice, he should have had no hesitation in ruling that the persons supplying it were legally responsible, but this had not been shown, the captain acting to the best of his judgment, and not giving it for dysentery. The jury returned a verdict of "death from disease of the lungs, accelerated by scurvy," and also expressed an unanimous opinion that the lime-juice tested by Dr. Dickson was of bad quality. Dr. Dickson said he thought it only right to add that by direction of the Board of Trade he had made inquiries, and found the ship to have been well found in other respects with good accommodation, but a supply of good lime-juice was nevertheless requisite.

**DEATH FROM CHLOROFORM.**—An inquest was held on Wednesday week, at the Bank of England Tavern, Paddington, by Dr. Lankester, on the body of Edward Morrell, of 4, Union-street, Berkeley-square, a stableman, who was killed by the application of chloroform in St. Mary's Hospital. The deceased, a well-made, healthy man, was thrown out of a gig he was driving last Monday, and dislocated the thumb of his right hand. He went to the St. Mary's Hospital, where the surgeons endeavoured without success to reduce his thumb. They then suggested that he should take chloroform, whilst they would make a second and more painful attempt, but the wife of the deceased, who was with him, said he repeatedly and emphatically said he could not take chloroform, he could not bear it, and she implied in her statement to the jury that he had been compelled to take it against his will. After her interview with him the surgeons and the chief nurse state, deceased consented to take chloroform. Mr. Moore stated in his evidence that he administered to deceased for about three or four minutes, during which time he did not inhale more than one drachm. Witness noticed the pulse suddenly cease beating, and in a moment the patient was dead. During six months that witness had operated at the hospital he had administered

chloroform in about a hundred cases without any fatal result. Deceased died from the effect of the chloroform. After a lengthened inquiry the jury returned a verdict of "Accidental death."

**OVARIOTOMY.**—At a meeting of the Committee of Queen Adelaide's Dispensary, Bethnal-green, held March 7th, it was resolved that a room in the new building should be devoted to the above operation, under the care of Mr. Maunder, the consulting surgeon.

**PAUPERISM.**—The return issued by the Poor-law Board for the month of December shows that at the close of the year 1866 the number of paupers in receipt of relief in England and Wales exceeded 900,000, showing an increase of 2.5 per cent. as compared with the corresponding period of 1865, but a decrease of 2.6 per cent. as compared with 1864, owing to the improvement since then in the manufacturing districts. The increase of pauperism at the close of 1866 was not very great in any division of the kingdom except the metropolis; but there it exceeded 20,000, and amounted to nearly 20 per cent. The number of persons receiving out-door relief in the metropolis increased from 71,312 at the end of 1865 to 89,727 at the end of 1866.

**REPORTED DEATH OF DR. LIVINGSTONE.**—The following letters appeared in the *Times* of Thursday:—

"To the Editor of the *Times*."

"SIR,—With profound grief, which I am sure will be shared in by the nation at large, I transmit to you the following letter from Dr. Kirk, the former companion of Livingstone, and now Vice-Consul at Zanzibar, addressed to the Assistant-Secretary of the Royal Geographical Society.

"If the detailed accounts which are on the way to myself should arrive before Monday, they will be communicated to the Society on the evening of that day.

"It appears that my lamented friend had crossed the Lake Nyassa to its western side, and was there attacked by the same treacherous people, the Mazite, a branch of the Caffre race, described by him in his last book of travels. It may be as well to state that the nine Johanna men who escaped, and on whose evidence alone we at present have to rely, are natives of the Comoro Islands.

"If this cruel intelligence should be substantiated, the civilised world will mourn the loss of as noble and lion-hearted an explorer as ever lived.—I am, sir, your obedient servant,

"RODERICK I. MURCHISON.

"Royal Geographical Society, 15, Whitehall-place.

"Zanzibar, Dec. 26, 1866.

"MY DEAR BATES,—I have written fully to Sir Roderick three weeks ago, via the Cape of Good Hope and St. Helena, again via Mauritius and Suez, with all information we yet have got regarding poor Livingstone.

"As I am going to Kilwa and Mikindany for a few days to see if anything is there known of the sad story, and to seek for any letters which may have been sent by Dr. Livingstone before crossing Lake Nyassa, I write a note to you that may go by any ship passing here while I am absent. On December 5, nine Johanna men of the party which accompanied Dr. Livingstone came to Zanzibar, reporting that on the west of Nyassa, sometime between the end of July and September, they were suddenly attacked by a band of Mazite, and that Dr. Livingstone, with half his party, were murdered. Those who returned escaped, as they say, through being behind and unseen, and they all depose to having helped to bury the dead body of their leader the same evening. Although in the details and in other things the accounts of the various men differ, they all agree that they saw the body, and that it had one wound, that of an axe, on the back of the neck. One man saw the fatal blow given.

"The attack was sudden, and Dr. Livingstone had time to overpower those who faced him, and was struggling to reload when cut down from behind. I fear the story is true, and that we shall never know more of its details. Full statements have gone home, but this may reach Aden by an American vessel during my absence.

"You will see, if this arrives first, that we have sad news for the Society on the way.

"I remain, yours,

"J. KIRK."

## Notices to Correspondents.

Communications to the London Editor should be addressed to 20 King William-street, Strand; to the Edinburgh Editor, at MacLachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

All Contributions are attentively considered, and unaccepted MSS.

are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be legibly written, and only on one side of the paper.

When proofs are forwarded it is of the utmost importance that they should be corrected and returned without delay.

Owing to great pressure on our space, we are compelled to defer the publication of several papers and letters till our next.

### THE HORRORS OF CHIGNONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your contemporary may be quite right in directing attention to the danger of wearing false hair, and warning us of its attendant evils; but it is somewhat remarkable that the results anticipated have not been realised ere this. It is well known that our grandfathers and grandmothers wore false hair more generally than our wives and daughters; that it was usual to shave the head in order to wear a flowing wig. A glance at any portraits of the time of Charles II. will show how general the practise was in those days; even now in the Royal and many noble establishments, the attendants have to wear wigs to ensure cleanliness.

Respectable hair-dressers and wig-makers are supplied by regular hair merchants, of whom there are but three or four in London. By inquiry of one of these manufacturers, as they are called, I learned that they import the raw material chiefly from Germany and Italy. After passing it through a machine to remove gregarian deposit, &c., &c., they wash, card, boil, and bake it before putting it forward for sale. In each operation it passes under the practised eye of experienced workmen, who see that it is thoroughly cleansed from all impurities, and it would be impossible for such parasitical inhabitants to remain even in embryo; such hair is necessarily expensive, the supply is limited, and becomes yearly more so.

That what he calls "church-yard" hair is used for chignons is possible; doubtless, many tresses shorn from heads burning with fever find their way to the shops of the lower class hair-dressers, and by them used without preparation, and decorate the heads of their customers; but such hair would not be purchased by the regular dealers, for the simple reason that it would be destroyed in the course of preparation. Such hair is excessively brittle, vitality being destroyed at the root. Healthy hair, on the contrary, is elastic, and may be worn and brushed regularly for years.

Now, as a medical man, let me offer one word of advice for the fair wearers: buy of respectable dealers; brush and comb as regularly and thoroughly your artificial as you do your natural curls; use the same means to keep them clean and glossy; do not sleep in them, and rest assured there is no more danger from the one than the other.—I am, sir, yours, &c.,

SCALPEL.

### LADIES' SKIRTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Now that dry weather is likely to set in, it may be suggestive of a much-needed reformation to mention that I have met with at least one case of obstinate irritability of the mucous membrane of the trachea, which I can affirm to have arisen from the inhalation of dust tossed up by a lady's skirt. I suspect that many cases of the same complaint, as well as of conjunctivitis and ophthalmia, might be traced to the same cause; for who can say what animal virus, or what vegetable or mineral irritant, may not be contained in the dust tossed up by a long skirt, and then introduced into the nose, eyes, and throat of the by-passer.—Yours respectfully,

E. CULLEN.

### ON THE CURABILITY OF THE DEAF AND DUMB.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following question has been forwarded for examination at the ensuing Medical Congress in Paris, will you therefore oblige me by presenting it to your readers, especially as a correspondent in a Bristol paper of this week appears much interested in their welfare by only caring for the present half measures:

"On the curability of the Deaf and Dumb: their present care being entirely under Ladies and Gentlemen, the Medical Profession having no charge of them towards their cure, attention being paid to their state since 1837, a lecture thereon being delivered in the Bath Guildhall in 1856, when a Petition to the House of Commons was numerously signed, and duly presented and registered. That the cause of should be ascertained by the aid of registration of every infant at a month old, whether deaf or not."—I am, sir, faithfully yours,

WILLIAM PARKER, M.R.C.S.L.A.C.

### CHLOROFORM ACCIDENTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As bearing on the progress of anesthetics and the caution necessary still in the administration of these agents, it would be well to note that the last fatal accident in London was while using an apparatus, hitherto deemed infallible in warding off accidents—the balloon appa-

ratus—and this is the second accident of this kind that shows us the inutility of trusting to mere mechanical arrangements to keep off danger. Sabarth (the Dr. Snow of Germany) has mentioned thirty-six deaths from use of ether, so that even here we have not much to depend on; while of "mixed vapours," also believed to be so safe, I have met recently in journals not less than four deaths. Everything thus far, indeed, points rather to a wider and better study of chloroform itself.—I am, &c.,

CHARLES KIDD, M.D.

P.S.—The chief number of deaths from anesthetics still continue to be in trivial operations, showing the value of anesthesia by ice or ether spray. Several very troublesome sloughing wounds, and possibly pyæmia, have, however, followed the too deep congelation by ether.

## LATEST INTELLIGENCE.

### THE PRINCESS OF WALES.

Just as we are going to press, news has reached us from a reliable source that the symptoms have taken a rather alarming turn, and that Her Royal Highness is in a most critical state. In chronicling this sad intelligence, we have only to express a hope that the natural affection everywhere entertained for Her Royal Highness may have given rise to an exaggeration of the danger.

## Appointments.

ANDERSON, D., L.K.Q.C.P.I., has been appointed Medical Officer and Public Vaccinator for the Cloghan Dispensary District of the Stranorlar Union, County Donegal, vice R. H. Pope, L.R.C.P.Ed., resigned, and appointed Medical Officer and Public Vaccinator to the Donegal Dispensary District and the Workhouse of the Donegal Union.

ARDEN, S., M.R.C.S.E., has been appointed Medical Officer for District No. of the Eccleshall Bierlow Union, Yorkshire, vice J. Gregory, M.R.C.S.E., deceased.

BURKE, T., M.D., has been elected Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Feakle Dispensary District of the Scariff Union, County Clare, vice P. V. M'Donough, L.F.P. & S. Glas., resigned.

CALDWELL, J. T., M.R.C.S.E., has been appointed House-Surgeon to the Dispensary, Chorlton-upon-Medlock, Manchester, vice John Rayner, L.R.C.S.Ed., resigned.

CRANE, C. A., M.D., has been appointed Medical Officer for the Hallaton District of the Uppingham Union, Rutlandshire, vice J. H. Spencer, M.R.C.S.E., resigned.

DWYER, H., L.K.Q.C.P.I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Newport Dispensary District of the Nenagh Union, Co. Tipperary, and Medical Officer to the Constabulary of Newport, vice J. B. Kittson, L.R.C.P. Ed., deceased.

GODRICH, T., L.R.C.P.L., has been appointed Medical Officer for No. 2 or Walham-green District of the Fulham Union, vice N. Avent, M.R.C.S.E., resigned.

LEE, R. J., M.B., has been appointed Physician in Ordinary to the Western General Dispensary, Marylebone-road, vice F. Bagshawe, M.D., resigned.

M'CARTHY, J., L.R.C.P.Ed., has been appointed one of the Resident Medical Officers to St. Mary's Hospital, Manchester.

MZADE W., L.K.Q.C.P.I., has been appointed Medical Officer to the Cloyne Dispensary District of the Midleton Union, Co. Cork.

MURRAY, Mr. W. B., has been appointed Medical Officer for the Bockleton District of the Tenbury Union, Worcestershire, vice J. L. Sweet, M.R.C.S.E.

NEALE, J., M.D., has been appointed Honorary Surgeon to the Birmingham and Midland Counties Lying-in Hospital and Dispensary for Diseases of Women and Children, vice J. Archer, F.R.C.S.E., resigned.

PERKINS, J. B., L.R.C.P.Ed., F.S.A.L., has been appointed Resident Physician to the Royal Hospital for Sick Children, Edinburgh, vice W. T. P. Wolston, M.B., resigned.

ROWE, Mr. T. H., has been appointed Medical Officer for the Haverfordwest District and the Workhouse of the Haverfordwest Union, Pembrokeshire, vice J. D. Phillips, L.F.P., & S. Glas., resigned.

SMITH, C., M.R.C.S.E., has been elected Surgeon to the Halifax Infirmary.

SUTTON, F., M.R.C.S.E., L.S.A.L., Assistant Medical Officer of the Norfolk County Asylum, Thourpe, near Norwich, has been appointed Medical Superintendent of the Norwich Borough Asylum.

SWEET, J. L., M.R.C.S.E., has been appointed Medical Officer for the Tenbury District and the Workhouse of the Tenbury Union, Worcestershire, vice F. F. Thompson, M.R.C.S.E., deceased.

SWELLMAN, Dr. R., has been appointed Assistant Medical Officer to the Durham County Lunatic Asylum at Sedgfield, vice J. A. Campbell, M.D., appointed Assistant Medical Officer to the Cumberland and Westmoreland Asylum at Carlisle.

VALLANCE, T. J., M.D., has been appointed Medical Officer to the Whitechapel Union Industrial Schools at Forest-gate, vice James T. Vallance, M.D., resigned.

## Medical Diary of the Week.

WEDNESDAY, March 13.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Huxley, "On the Osteology and Dentition of the Sauropsida, or Reptiles and Birds."

ROYAL COLLEGE OF PHYSICIANS.—5 P.M. Croonian Lectures: Dr. Andrew Clark, "On the States of Lung commonly comprehended by the term Pulmonary Phthisis."

HUNTERIAN SOCIETY.—7½ P.M. Council.—8 P.M. Mr. Maunder, "On Abscess of the Prostate, and Cases of Circumcision in the Adult."

MICROSCOPICAL SOCIETY OF LONDON.—8 P.M. Mr. W. Whitney, "On the Changes which accompany the Metamorphosis of the Tadpole, in reference especially to the Respiratory and Sanguiferous Systems."—Dr. Mackintosh, "On a Gregariniform Parasite."—Mr. Lobb, "On a New Form of Paraffin Lamp."

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.—8 P.M.

THURSDAY, MARCH 14.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M.

ROYAL INSTITUTION.—3 P.M. Prof. Frankland, "On Coal Gas."

FRIDAY, MARCH 15.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Huxley, "On the Osteology and Dentition of the Sauropsida, or Reptiles and Birds."

ROYAL COLLEGE OF PHYSICIANS.—5 P.M. Croonian Lectures: Dr. Andrew Clark, "On the States of Lung commonly comprehended by the term Pulmonary Phthisis."

ROYAL INSTITUTION.—8 P.M. Mr. E. B. Tylor, "On the Early Mental Condition of Man."—Dr. J. B. Pettigrew, "On Modes of Flight and Aeronautics."

SATURDAY, MARCH 16.

ROYAL INSTITUTION.—3 P.M. Prof. Frankland, "On Coal Gas."

METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—7½ P.M.

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

WILKINSON.—On the 23rd ult., at Aston-road, Birmingham, the wife of A. G. Wilkinson, M.R.C.S.E., of a son.

LANSDOWN.—On the 26th ult., at Bristol, the wife of F. Poole Lansdown, M.R.C.S., of a daughter.

GIMLETTE.—On the 28th ult., at Merton-road, Southsea, the wife of Dr. Gimlette, H.M.'s ship "Lord Clyde," of a son.

FYFFE.—On the 1st inst., at Rodney-place, Clifton, the wife of Dr. Fyffe, Staff Surgeon Army, of a daughter.

BOYD.—On the 3rd inst., at Blenheim-street, Newcastle-on-Tyne, the wife of Dr. Jas. Boyd, L.R.C.S.E., of a daughter.

BRAID.—On the 4th inst., at Burgess-hill, Sussex, the wife of J. Braid M.D., of a son.

### MARRIAGES.

MURRAY—STEWART.—On the 12th ult., at Paisley, William Murray, M.D., of Burley in Wharfedale, Leeds, to Sarah Anne, eldest daughter of James Stewart, Esq., of Paisley.

WOTHERSPOON—PRIMROSE.—On the 27th ult., at Royal-crescent, Glasgow, William Wotherspoon, L.F.P. & S. Glas. to Jessie M'Farlane, only daughter of Peter Primrose, Esq.

### DEATHS.

HITCHMAN.—On the 3rd [ult., at the Arboretum, Leamington, John Hitchman, M.R.C.S.E., for many years Surgeon to the Leamington Hospital, and the Warneford General Bathing Institution.

MORRIS.—On the 21st ult., Wm. Morris, M.R.C.S., of Tudor-road, Upper Norwood, formerly of Camberwell, New-road, aged 66.

SANDWITH.—On the 4th inst., T. Sandwith, M.D., of Park-terrace, Beverley, J.P., and late Surgeon to the County Prison for thirty years.

BURN.—On the 4th inst., at Cheltenham, R. D. Burn, M.D., Assistant-Surgeon Royal Artillery, on half-pay, aged 82.

FFOLIOTT.—On the 1st inst., at Clonskilly, of malignant typhus fever, Saunders Ffolliott, Esq., M.D., third surviving son of the late Wm. Ffolliott, Esq., M.D., F.R.C.S.I.

## Lectures.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

## THE GULSTONIAN LECTURES.

By Dr. REGINALD SOUTHEY.

## ABSTRACT OF LECTURE III.

DELIVERED MARCH 8, 1867.

## THE NATURE AND AFFINITIES OF TUBERCLE.

*The three gland tracts of scrofula: the cervical, the thoracic, and the mesenteric. The course of scrofulous disease: its characteristic features. Why scrofulous pneumonia commits greater ravage at the apex of the lung than at its base. The distinction between scrofulous and tuberculous disease: in diathesis, in cachexia, and in pathology. Although thus specifically distinct, these two diseases exercise no excluding influence on each other. Acute and chronic tuberculosis. Inherited proclivity to tubercular disease. Acquisition of the disease. Inducing causes. The exciting cause. What period of life most prone to tuberculous disease. The first symptom of the established disease—a special form of irritation. The "Reiz" of Virchow. The development of the new growth out of connective tissue: its affinity for certain primary sites, and secondary dissemination by infection from these places. The parts most prone to be the seat of secondary distribution or metastasis. Therapeutic indications. Summary. Conclusion.*

IN scrofula, said the lecturer, there is a build of body which distinguishes its diathesis from that of tubercle. Scrofulous persons are large-framed and leanly built; their complexions are muddy, and they are generally torpid in mind and body. Those, however, who possess a tuberculous diathesis are tall and thin, light-weighted and slimly built, with fine silky hair, transparent skins, and often ruddy-complexioned cheeks. They are premature in everything, nervous, quick, and irritable. The scrofulous diathesis marks a preternatural vulnerability, to unhealthy, chronic inflammations; the tuberculous, a particular proclivity to one special form of disease; the first evidence of established tubercle is the presence of this new growth, the first proof of established scrofula, a glandular enlargement, the scrofulous tumour, which has succeeded some slight irritation or local ulceration. The lymphatic system appears the vulnerable part in scrofula; we may suppose the lymph glands and their vascular prolongations to be so far feeble in construction, that they are thrown out of gear with abnormal facility. The disease appears limited to certain tracks, of which the three principal are the cervical, the thoracic, and the mesenteric.

This circumscription of the affection within certain districts, is due to the primary irritation being confined in particular tissues, and extending only through particular channels; these tissues are the intercellular or submucous, and the channels are the lymph vessels. Dr. Southey next described the scrofulous tumour, its course and progress, and showed why scrofulous pneumonia committed greater ravage at the apex of the lung than at its base, arguing strongly that "vomice" were evidence of abscess, but not of the cause of that abscess, and therefore not necessarily of tubercle. Amongst other reasons for this proclivity to infarction of the apices of the lungs, he noticed the larger relative size, and more embryonal state of the alveoli in the upper parts of the lungs. Scrofulous affections of the lung tend also to the formation of scar tissue, and to produce increased thickness of the walls of the bronchi, a condition of things especially favourable for the subsequent development of tubercle; finally, he said that the two diseases no way excluded each other, although in diathesis,

cachexia, and in pathology, they were specifically distinct. Scrofula is pre-eminently a chronic complaint; its duration is the life-time of the individual thus afflicted, it is attended by only slight sympathetic fever, and this succeeds local lesions, whereas tuberculosis is an acute disease, febrile from the first, the acuteness of whose course is accurately measured by the amount of fever manifested. The effects of remedies also mark a striking difference in the two diseases, the one being amenable to good influences, and sound principles of treatment, whereas in the other we have as yet found out no febrifuge for the fever, and no specific medicine that operates against the development of the new growth that induces it. The strongest predisposing course of tuberculosis is the inheritance of a tuberculous taint, and statistics incline us to believe that sons inherit this proclivity more from their fathers, and daughters from their mothers. The susceptibility of individuals to become tuberculous is, speaking generally, greatest at the earliest periods of infancy, and diminishes with advancing years. Youth and childhood are more vulnerable because the tissues are then softer, and the habits of right in their development have been inculcated for only a short period of time. The disease, however, cannot always be derived from an hereditary cause, since, as it shortens life and exerts its greatest destructive influence upon the human race anterior to puberty, it limits the multiplication of the human species and should tend to die out itself by natural extinction; since, however, tubercular affections increase rather than diminish with the advance of civilization, we are compelled to accept its renewal or acquisition afresh from time to time. Sudden changes in the habits of life, sedentary employments, the crowding of people together in ill-ventilated rooms, exhausting over-work of mind and body; mal-hygiene, in a word, are the most frequent inducing causes of tuberculosis.

The exciting cause the lecturer attributed to some special form of irritation which forced the connective tissue elements to develop in a wrong direction. There ensues a local congestion round the new growth which should appear to develop itself with extreme rapidity. In the acute form of the disease in various parts of the body at the same time, and in the chronic in successive crops, tubercle possesses favourite primary sites; such are the serous membranes, the testicle, the kidney, the fat tissue of the omentum, the medullary tissue of bone; it is rare in the muscles, mammary gland, the ovaries, thyroid gland, the tonsils, the salivary glands, the skin; very rare in the stomach, and scarcely ever found in the œsophagus. The primary nodules are nests of infection, as Laennec formerly taught, the disease being disseminated first in the immediate neighbourhoods of the primary tubercle growths, and then by metastasis from these, probably in the course of the lymphatics from the parts they first attacked. Thus the prostate affects the vas deferens and epididymis, the intestines, the lacteals, and mesenteric glands, and the solitary conglomerate of the brain, the cerebral meninges. The principle of treatment is to allay irritation, and to limit, so far as possible, the first infecting source. Any sudden change of climate, or of their habits of life, must be strictly avoided by those who inherit a proclivity to tuberculosis. The most beneficial climate for such individuals is that in which the barometer and thermometer experience smallest variation throughout the year; finally, cold and moderately moist mountainous districts often benefit those who are afflicted with scrofulous lung abscess; but cold and variable temperatures do not suit tuberculous subjects.

The principal aim of the lecturer was to establish the difference that subsists between tuberculous and scrofulous affections, that they were allied to each other only in so far as they both could be said to belong to one large family of diseases—those, namely, which may be called lymphomatous formations—all such affections presenting certain affinities to tubercle, and when grouped round about it affording us a keener insight into its nature.

## THE CROONIAN LECTURES

DELIVERED AT THE

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

By Dr. ANDREW CLARK.

## ABSTRACT OF LECTURE I.

DELIVERED FRIDAY, 8TH MARCH.

THE lecturer began by saying that though the scientific sin chiefly prevalent among us in these days was the reproduction of old ideas under the guise of a new and often specious terminology, we were not free from the opposite sin, which, though more honest in character, was not less injurious in its results. This was the repression and concealment of new ideas under the cloak of an antiquated and sometimes absurd phraseology. Neuralgia, rheumatism, gout, epilepsy, apoplexy, and Bright's disease were adduced as examples of terms involving the most diverse dynamic disturbances or organic states. So it was with the term chronic pulmonary phthisis, which, though comprehending various pathological states of lung, was commonly referred to one, or at most two, anatomical elements. The results of this mode of viewing the subject were shown to be disastrous alike to the science and art of medicine. The lecturer then enumerated and illustrated the following causes of this confusion:—First. Symptoms of damage to an organ are often more allied to disturbance of function than to the nature of the disturbing cause. Second. Our still imperfect pathological knowledge. Third. The fact that like pathological products are often brought about by unlike causes, and that changes apparently similar to the naked eye are found quite dissimilar when examined by the microscope; and Fourth. The effect of prevailing theories influencing our perceptions to see and our judgment to require only what was in unison with them. More accurate views of the pathological anatomy of phthisis were now dawning upon us, and the way to these had been opened by the labours of Addison, Williams, Peacock, Bennett, Wilks, Cotton, Stone, Sutton, and Greenhow. The light which Germany boasted to have thrown upon the changes undergone by the lung in phthisis, Dr. Clark declared to be light borrowed from England and transmitted back to us through a different and less transparent medium. He referred at length to the part which inflammation plays in the destruction of the phthisical lung, and gave the honour of this discovery to Addison of Guy's. Dr. Clark next alluded to the famous "Cellular Pathology" of Virchow, and endeavoured to prove that what was new, true, and valuable in it had long been anticipated by the genius and foresight of John Goodsir, whom death, with untimely hand, had just taken from amongst us. Admitting Virchow to be endowed with a splendid and variously gifted mind, the lecturer averred that his faculties were not, as in a great physician, so adjusted as to enable him to keep the exercise of imagination within the domain of objective reality to see truth from every side, and to force it into fruitful application to the necessities of men.

The lecturer then proceeded to show, that in persons dying of chronic phthisis, different states of lung were found, each of which was characterised during life by a more or less distinctly marked group of symptoms. What, then, were these different states of lung found after death? What the groups of symptoms by which, during life, these states were to be recognised? These questions were not yet wholly answered; and it was only by the careful collation and comparison of the results of clinical and pathological enquiry, that such problems could be finally solved. Dr. Clark proposed, on the present occasion, to confine himself to such a description of the pathological states of lung commonly comprehended by the term phthisis, as would serve for their distinction, and to avoid not only a very minute account of these states, but also historical and critical examination of the opinions of others, except in so far as might be necessary to attack a flagrant error or defend a cardinal truth. He proposed to speak chiefly from his personal experience, as in part expressed by his collection

of specimens shortly to be placed in the College Museum. He then proceeded to map out the distinctive states of lung occurring in phthisis, and explained his reasons for declining at present to introduce a new nomenclature. After a few clinical sketches of the leading types of phthisis, the lecture concluded with a description and explanation of the table subjoined:—

NAME.	CHIEF ANATOMICAL CHARACTERS.
1. Tubercular granular or specific phthisis.	The true grey granulation; pigmented tubercle; fibrous tubercle; cellular tubercle?
2. Scrofulous or epithelial phthisis.	Primitive yellow tubercle; accumulation, cheesy degeneration and disintegration of epithelium-like cells.
3. Catarrhal or bronchial phthisis.	Ulceration of bronchi, with adjacent fibroid and cellular deposits and cheesy degeneration of the same.
4. Pneumonic phthisis.	Disintegrations of recent or old deposits occurring in vesicular, lobular, or lobar pneumonia—primary or secondary, ordinary or scrofulous.
5. Fibrous phthisis (cirrhosis: chronic or interstitial pneumonia).	Fibroid or fibrous deposits, with cheesy degeneration of included portions of lung, due to— a. Mechanical irritation (as in masons, grinders, miners, &c). b. Chronic pleurisy. c. Rheumatic inflammation of interlobular tissue. d. Constitutional states, as in granular kidney and liver.
6. Amyloid phthisis.	Circumscribed or diffuse cellular formations, infiltrated with the amyloid material.
7. Syphilitic phthisis.	Cheesy disintegration of nodules of nucleo-fibrous tissue, and diffuse infiltrations of the same.
8. Hæmorrhagic phthisis.	Cheesy degeneration and disintegration of nodules of extravasated blood.
9. Embolic phthisis (including pyæmic deposits and suppurations).	Cheesy degeneration and disintegration of grey or yellow deposits, arising directly or indirectly from pulmonary emboli, coming from the liver, lymphatics, or veins.

## CLINICAL LECTURES

DELIVERED IN

STEEVENS' HOSPITAL,

TOGETHER WITH

OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,

PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,

PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

## OBSERVATIONS ON THE HEMORRHAGES.

INTRODUCTORY to the consideration of the more important of the hemorrhages, I shall make some remarks upon *Epistaxis*.

In the works of systematic writers this variety of blood-flow is, with few exceptions, deemed so trivial, so unimportant, that scarcely a short chapter is devoted to its distinct consideration. Yet, if closely looked into in all its bearings, relations, and varieties, it will be found, by both the speculative and the practical pathologist replete with interest. One form, which I shall term the spontaneous or

idiopathic variety, furnishes us with the surest index of that state of the system termed the hemorrhagic.

Of the hemorrhages this is generally (there are, however, exceptions) the least formidable variety; it is, nevertheless, the most frequently valuable as a constitutional index.

Furthermore, there have been cases of epistaxis (and of these not a few) in which the torrent of extravasated blood has been so copious and so prolonged, as seriously to peril life; and in the treatment of which sound judgment and promptitude in action have been imperatively demanded. Judgment, to determine the moment when, without injury to the patient (for it is often a salutary effort of nature), the hemorrhage may be checked. Promptitude, in effecting, speedily and thoroughly, the object of arresting the destructive overflow of the vital fluid.

Close observation of the natural process by which this exudation is effected, affords much useful instruction, and teaches us what the true nature is, of many of those internal and unseen hemorrhages, which were formerly, and still are popularly, referred to the rupture of the trunk of a blood-vessel. This, doubtless, is the occasional, but comparatively rare cause of a fatal hemorrhage. The most frequent cause of hemorrhages, often fatally profuse, is,—as may be observed in epistaxis, capillary exudation,—blood extravasated, not from an arterial or venous trunk, but from myriads of turgid capillary and exhaling vessels.

A remarkable case, elucidating this truth, occurred at Stevens' hospital. A young man labouring under hemoptysis was admitted a few hours before my morning visit. Having spoken to, examined, and prescribed for him, I passed on. Whilst talking to the patient who lay in the next bed, I heard a gurgling sound and turned round: the man to whom I had but a moment before been speaking was dead,—was suffocated. A minute and careful examination disclosed neither tubercle, nor cavity, nor consolidation, nor lobular nor diffuse apoplexy, nor ruptured trunk, in any part of the parenchyma of the lungs; all the larger bronchi were nearly filled with blood, which was coagulated in them, particularly at and about the bifurcation, so as to obstruct the ingress of air. It was a case of bronchial hemorrhage,—of copious sweating of blood from innumerable capillary tubes distended with blood. I say sweating, because I doubt there being any rupture or breach of surface.

In some forms of fever, sweating so profuse has occurred as to soak through the bed, and to accumulate in large quantities in a vessel placed underneath.

A capillary extravasation of red blood may be as profuse as a capillary exudation of white blood. A mucous membrane may copiously sweat blood; I have seen the same thing happen from the pores of the external skin of the face. One case, a very remarkable one, I shall briefly refer to. The patient was a young woman four or five and twenty years of age; herself intensely strumous, as were also her parents and brothers; she was subject early in life, both before and after puberty, to spontaneous epistaxis. She was attacked with fever. The symptoms presented the usual aspect of scarlatina; a dusky red rash was universally diffused, with sore and swollen throat, but no ulceration. There was a well-marked febrile movement in the system. On the third day the whole characters of the case were altered: fever subsided, the throat was no longer complained of. Quite suddenly, petechiæ, some very small, some as large as a split pea, appeared under the cuticle, and were rapidly scattered over the whole surface; their colour was livid, and they soon became black as ink. After the lapse of a few days dark grumous blood began to ooze from the gums, from all the points of junction of the internal and external skins, and from the nares, and appeared mixed with the urine and feces; patches of ecchymosis stained the skin over large spaces. The debility, vascular and muscular, was extreme, and the fetor emanating from the breath and whole person in the highest degree offensive. All signs of scarlatina vanished.

In this miserable state, with a gradual augmentation of

every worst symptom of purpura hemorrhagica in its most malignant form, she lingered on for nearly three weeks.

For many days before death the following remarkable phenomenon manifested itself. Blood oozed and descended in streams from the pores of the skin of the face, and, of all the external skin from those of the face only. With intense interest I watched the process. The surface having been wiped clean, minute globules of dark blood were seen to exude from every pore; these rapidly increased in size, coalesced, and formed streams which flowed on every side; a profusion of blood was thus extravasated, in like manner as drops of rain increase in size in descending, unite, and form tortuous little rivers, on the glass of the window of a carriage.

Whether attributable to the great tenuity of the Schneiderian membrane, connected with the delicacy of the sense of smell, or to the highly vascular net-work of this membrane, or to the copiousness of the supply of blood to the brain, or to all unitedly, certain it is, that of all the hemorrhages, that most frequent of occurrence is epistaxis.

To this variety of hemorrhage some are much more prone than others, and this may depend not only on constitutional causes, such, for example, as mal-organized blood, but also upon superior delicacy of the mucous membrane and its vessels; a condition of mucous membrane, as well as of external skin, frequently characteristic of struma. Whatever be the cause, the fact is certain, that blood streams from the nares with more facility than from other mucous surfaces.

This is the case, in varied degrees, at every period of life, but much more remarkably so at the extremes of life; the most frequent time of occurrence of epistaxis is, however, during the period of growth. I have many interesting cases recorded which prove that this hemorrhage, having appeared in early youth, disappears during mediæval life, and returns as years accumulate and old age approaches. The period of senility varies much in differently constituted individuals, and is hastened or retarded by the events and habits of the past life.

It is a curious fact that the epistaxis of the growing period of life should, in so many instances, resume its sway toward its close. It may be termed the *Epistaxis redux* of advanced age. Within the last few days I attended a lady, now in her seventy-fourth year, affected with severe hemoptysis. Thrice before, several weeks having intervened, she was similarly affected, and twice previously to the attacks of hemoptysis, she bled profusely from the nose. Inquiry elicited the following facts: In early life, antecedent to the full establishment of the catamenia, she had been a martyr to idiopathic epistaxis; at the menstruating periods she suffered habitually much pain, and the discharges were very profuse, and at the period of the cessation of the menses, when they recurred at long and irregular intervals, the hemorrhage was excessive, and the blood came down in large clots. She had been married at a young age, but had never been pregnant. This old lady does not appear to labour under any organic disease; the heart's action and the breath sounds are perfectly normal. I have on record several equivalent cases.

Considering, then, the facility with which blood is exuded from the nares, it is not contrary to anticipation that mental emotions should so affect the vessels of the brain, as frequently to give rise to epistaxis. Congestions, inflammations, and diseases of the brain, are frequently preceded and accompanied by epistaxis; this I shall have occasion hereafter more particularly to notice. Those mental emotions which produce cerebral congestion (for some, not all, produce this effect), are often signalized, and relieved too, by a flow of blood from the nares. Epistaxis is thus often a naturally provided safety-valve. The following event, of which I happened to be an eye-witness, illustrates this principle. A child of some two and a half or three years of age, in attempting to descend a flight of stairs, fell, and rolled down to the first landing-place. He was much hurt, and cried bitterly. The nurse, a strong plethoric woman, greatly attached to the child, ran

to take him in her arms; the child's father, at the head of the stairs, sternly forbade her to touch him; she was compelled (standing at the foot of the stairs) to look on. Another attempt (after many efforts and touching appeals for help) was made by the child to descend. Again, he fell. The nurse could endure it no longer; her feelings overpowered her. She rushed upstairs and took him in her arms, and exclaimed, in a highly excited tone, "If it cost her her life she would save the child." She became deeply flushed, and a copious stream of blood rushed from both nostrils. This woman, whom I had frequent opportunities of afterwards seeing, had never been subject, previously or since, to any form or variety of abnormal hemorrhage. This was a well-marked instance of a strong mental emotion causing epistaxis of temporary origin, and altogether exempted from any pre-existing or hereditary hemorrhagic diathesis. I shall, on a future occasion, notice how frequently this diathesis, connected with struma, is hereditary.

A lady, in her fortieth year, of florid complexion, and uncontrolled temper, in a fit of furious and unrestrained anger, was seized with epistaxis. Blood from both nostrils flowed in profusion, and persisted so long that her family became seriously alarmed. When I saw her, she was nearly pulseless; there was a death-like pallor present, and a cold, clammy, perspiration; her voice was feeble, and she could articulate only in a whisper, yet she did not appear to be alarmed. There was no time to be lost; much blood still flowed; much descended from the posterior nares, and was swallowed; some hours previously she had vomited blood. Antecedent to my visit, all the usual means to check the blood-flow had been in vain employed. Upon close examination it was ascertained that the flow of blood was much more profuse from the left than from the right nostril; by means of a flexible catheter passed along the floor of the nose, a plug, with a strong silk thread firmly attached, was through the mouth introduced into the left posterior nostril. This completely controlled the blood-flow at that side; as it was not desirable too suddenly wholly to arrest the bleeding, the other nostril was not plugged. The loss on the right side became now comparatively small.

So much distress, so many unpleasant consequences have occasionally arisen from the plugging of both nostrils, that, whenever practicable, one of the air passages should be left free. The double plug is often needlessly applied. Sometimes, however, it is unavoidable. It may be well to remark, that if sponge be used for a plug, it is better to enclose it in lint, otherwise, when distended by moisture, it may so insinuate itself into the narrow spaces between the delicate bones of the nose, as to cause difficulty and even injury in its removal.

Months elapsed ere this lady recovered in health, strength, and complexion, from this profuse and prolonged nasal hemorrhage. In early life she had been subject to idiopathic epistaxis; her menses were always superabundant, sometimes extremely profuse. At each of her confinements her losses of blood were enormous. About a week before the attack of epistaxis she had menstruated copiously. Her habits of life had always been temperate. Thus, in this case, a fit of anger, or rather of fury, was the exciting cause of the epistaxis. But its dangerous profusion is to be attributed to the pre-existence of a well-marked hemorrhagic diathesis.

The leading facts of another somewhat similar case shall be briefly detailed.

Mrs. S., aged 49, has ceased for a year and a half to menstruate. She is now labouring under organic disease of the heart. The symptoms indicate the existence of contracted orifice of the mitral valve. She has had two severe attacks of rheumatic fever, one before puberty, one at the age of 26. Eight years have elapsed since she first complained of dyspnoea and palpitation. Thirteen years ago she sustained a severe mental shock, by the sudden and unexpected death of her mother, to whom she was fondly and devotedly attached; the more, perhaps, because, though long married, she was childless. The mental emotion produced by the suddenly imparted news of her mother's

death was very great, she was seized with violent headach, which was followed by most profuse epistaxis; for three days the hemorrhage never ceased. She lived in a remote part of the West of Ireland, and it was not until the fourth morning after the commencement of the attack, that the physician reached her house; he found her pulseless, and apparently dying. He plugged both nostrils; she was unable to articulate, and with difficulty could swallow; she lay for upwards of three weeks in a state of insensibility; this period of time was a blank in her existence. She slowly recovered, but her natural complexion, vigour, and strength, she has never since then repossessed. In her case it is especially remarkable that, from the earliest age up to the full period of puberty, she had been subject to idiopathic epistaxis, so much so as to interfere with all her girlish amusements and occupations. The flow of blood was never during her early life profuse, but occurred so frequently, sometimes spontaneously, sometimes from the slightest causes, that she lived in a state of perpetual apprehension. When the menses were fully established the epistaxis ceased, and did not again recur till, as related, a powerful mental emotion recalled the latent predisposition, and accounted for its all but fatal persistence and profusion.

In the pages of history we meet with several instances of hemorrhage produced by the most overwhelming of mental influences, wounded pride, thwarted and disappointed ambition. A Doge of Venice burst, as is narrated, a blood-vessel, and died suddenly, when he heard the bell of St. Mark's announce by its toll the appointment of his successor. At Salisbury, the perverse, mentally blind, and unfortunate monarch of England, James II., was, on the eve of an expected battle, which he never fought, seized with epistaxis. It continued, and confined him to bed for three days.

The influence of augmented heat or caloric upon the cerebral circulation, becomes a frequent cause of temporarily excited epistaxis. Hence it is that, at the hottest seasons of the year, hemorrhages in our climate are most frequent. Hence also it is that an overheated bath, heated rooms, indulgence in ardent spirits, the sun-stroke, violent exercises, so affect the circulation that hemorrhages oftentimes immediately ensue. Intense thought, long persisted in, renders the vessels of the brain turgid, and gives rise to a blood-flow.

Hence, too, the great imprudence and injury of ordering those patients threatened with phthisis, who evince the hemorrhagic diathesis, to overheated and dry climates; those who labour under what I have elsewhere termed hemorrhagic phthisis should never be sent to a climate which tends directly to augment the existing and often fatal evil.

Those causes which suddenly excite and stimulate the heart's action, so as to propel blood more rapidly to the brain, do, in many persons, give rise to epistaxis. In fevers, at the commencement of the stage of reaction, this is especially and strongly exemplified. A flow of blood from the nares is the starting-point of many fevers, of none more frequently than the Rubeolous.

Some months since I happened to attend two boys, each about ten years old, in the same room. They were playfellows and companions, but not relatives. I was much struck by the contrast between these two cases. One possessed a sound constitution, free from any hereditary taint, and had never been affected with idiopathic epistaxis. The other had not long recovered from a tedious and prolonged succession of strumous abscesses of the cervical glands, which left characteristic and deforming scars and cicatrices. From infancy he had been prone to distressing and perpetually recurring attacks of epistaxis. Twice the blood-flow was seriously profuse. Both these boys were attacked, within a few days of each other, with measles. At the time when the rash was beginning to appear they both complained of headach, and they both bled from the nose; the boy with untainted constitution had no recurrence of the bleeding, was greatly relieved by it, and passed through the disease without one untoward symptom; the boy who was marked with the signs of struma (both his parents were in-

tensely strumous) during three days bled so frequently, so copiously, that his life was endangered. The former was in a few days perfectly restored; but months elapsed ere he who was marked with struma resumed his former ruddy and deceptive appearance of health.

Thus were evinced, in strongly contrasted relief, the temporary and salutary epistaxis of a perfect constitution, and the protracted and exhausting epistaxis of the distinctly impressed strumo-hemorrhagic diathesis.

Here it may be noticed how very distinct the hemorrhage of incoming fever is from that which takes place towards its close. Epistaxis is the most frequent variety of bleeding during the hot stage; intestinal, sometimes uterine, when the fever is advanced; and when, at this stage, it, or any other variety of hemorrhage, sets in profusely, it is a most formidable symptom, and indicates the great change which has been wrought by continued febrile action in the component ingredients and constituency of the blood. At the ingress of the reaction of fever no material change has as yet been produced; towards the close the blood has been thinned and altered.

Of all the signs of the febrile movement the most invariable is wasting. No matter what the type, this is the most uniform result. Scanty are the supplies; the primary assimilative function is, in a great measure, suspended; so must be that of sanguification. The body feeds upon itself: as fever progresses, the blood becomes more and more attenuated; and in those fevers which are caused by malaria and by animal and other poisons, the blood becomes so deteriorated, so reduced in tenacity and density, that it oozes and is exhaled from mucous surfaces. Thus a passive hemorrhage is produced, altogether distinct from the active hemorrhage which so frequently, at the incoming of fever, relieves the tension and increased action of the vessels of the brain.

(To be continued.)

## Original Communications.

### REMARKS

ON

### AFRICAN, WEST INDIAN, AND OTHER FEVERS AND DISEASES.

By ALEXANDER LANE, M.D., Surgeon Royal Navy.

(Continued from page 212.)

FEVERS are treated symptomatically, as certain symptoms require certain medicines, thus ignoring the cause; you cannot allay the symptoms without diminishing or decreasing the strength of the poison, and if these medicines cannot do that, of what use are they? If you cannot prevent the blood running into a state of putrefaction, how can you cure the disease? Looking at it as a disease, can a locality be assigned to it? We have all the symptoms, but is it in the brain, or any of the organs, as the liver, spleen, kidneys, or is it in the skin, bones, muscles, arteries, veins, nerves? the whole system is affected, and therefore we can only refer it to a poisoned circulation, with a determination to the finer vessels of the alimentary tube, and its adhesions. When post-mortem examinations prove this in the more active and violent, the same will be the result though not so discernible, in all the milder cases; then to get rid of this stranger in the blood would seem to be the first duty we have to perform, as, so long as it is there, the heart will continue to drive the blood into and destroy the finer tissues.

Evacuants may lessen the violence of the symptoms, but they will not destroy the poison, nor prevent the blood from running to putrefaction; it will require a specific to do this, and mercury or preparations of potash will do it. I do not now refer to simple irritative fevers or febrile affections produced by some local irritative action, but to that produced by some peculiar poison—as soon as the system is

placed under their influence, the symptoms will soon disappear; mild tonics will restore the tone of the stomach, and convalescence will follow. Enemas composed of castor oil well beaten up with eggs and gruel will relieve the lower bowels, and a sleep and rest are absolutely requisite. I have found morphine to answer those purposes most admirably. When vomiting of blood supervenes, and indeed, when it becomes unusually violent, I have found a valuable remedy in the acetate of lead in doses of ten grains every two hours, or if the case is urgent every hour. I discovered about twenty-five years ago that this medicine was not poisonous when administered by itself, and published my cases in THE DUBLIN MEDICAL PRESS of that period; combined with opium its medicinal virtues are destroyed by chemical affinity; notwithstanding this and a similar discovery (?) made by a Dr. O'Grady of the Kilmainham Cholera Hospital seven years after, who had ventured upon seven grains twice or thrice a day. I believe, on perusing the columns of THE DUBLIN MEDICAL PRESS AND CIRCULAR of the present day, I find the old form still adhered to.

As soon as the rigors had ceased I gave immediately croton oil, and usually had the intestinal tube thoroughly cleaned and within an hour; I generally applied on the tongue, half a dozen drops at a time until the medicine produced the desired effect. I then placed the system, as soon as possible, under the influence of either of the former medicines; I gave large doses at short intervals until the desired effect was produced, and as soon as this had been obtained, I felt no further anxiety about my patient, that is as far as the poison was concerned. I had now to contend with debility, and endeavour to restore health as soon as possible, which is a task not so very easily accomplished in a tropical climate. I found plain cold water the best drink, and patients usually preferred it to any other, at least until the restoration of taste.

I never lost a patient from any kind of "fever" whose system I could place under the influence of either of the above medicines.

In this disease when medicines, in the iphigenia, were prescribed for symptoms, I observed that they did not produce the desired effect, no matter how frequently administered or how large the dose; this at the time occasioned much reflection and consideration, and was one of the causes of enquiry into the real nature of the disease, as I thought it strange at that time that they produced no alleviation whatsoever. The cause was in the system upon which they appeared to have no effect, there was a sort of "vis a tergo" behind, which had not been overcome, and as they seemed to have had no power over it, their administration was waste and loss of time.

A few words now regarding cholera. I am of opinion that whether it is called pure Asiatic, English, Irish, or French, the producing poison is essentially the same, differing only in degree of violence; for that poison which produces cholera will produce no other disease whatever, therefore the cholera poison is, like all other poisons, *sui generis*, and acts almost specifically upon the organs of nutrition, and is also very peculiar in its action. I do not know a disease which is not produced by some specific poison. Where the circulation is impeded there will be disease, but in general cases you expect a general issue; yet in this case, though general, it appears that it will attack the stomach and rectum and a portion, or perhaps the whole, of the colon, and leave the intermediate portion alone. The modes of treatment are so various, as a specific has not yet been found out, that it is really difficult to make a selection. The cases which came under my observation in India were about the usual type; however, they yielded to opium and brandy, with external stimulants and rubefaciants. The physicians I met with in India were certainly loud in their praises of opium, but, as they said—and I perfectly coincided with them—that opium, to be useful, must be given in large and powerful doses, and also in a liquid form, in consequence of its immediate action upon the coats of the stomach; and should a dose be rejected, there should be no hesitation about the second or third repetition, in fact repeated as often as necessary.

One afternoon at Jamaica, in 1827, I was sitting chatting with a brother officer in a verandah. We were helping to pass the time with cigars, having got tired of billiards. The verandah faced the sea, and a delightful sea breeze was blowing at the time, so that it was really quite cool and comfortable for such a climate. He got up suddenly and said he felt sick. "You are going to have an attack of 'fever,'" I said. "Nonsense," he replied; "why, a moment ago I never was better in all my life; it is that nasty cigar," he added, throwing the remains of it over the verandah. "Perhaps you will find it no nonsense," I said; "it is no joke, I can tell you, to be taken sick here; you may find it turn out a very serious affair." This I said by way of railery, not suspecting for a moment that he was going to have an attack of "fever," as the island was healthy at the time, and no suspicion had ever been entertained that such an event was likely to happen, more particularly as there was no apparent cause for it, and he was very abstemious. He walked to the end of the verandah and back to where I was seated, and was instantly seized with rigors. Within six-and-thirty hours he was buried. The question has often occurred to me—how long will the poison remain in the system until it makes its attack?

On questioning patients—and latterly I made these questions very pointedly—I never could elicit from them anything like a predisposition or symptom foreshadowing such an event.

The island is seldom free from sporadic cases, and the above was one of them. It produced the usual feeling of dread at the time, but as none others occurred in the space of a week, it was soon forgotten.

## HISTORY OF VACCINATION.

By W. H. SANDHAM, M.R.C.S., Cork.

THE brief history of vaccination published by me in THE MEDICAL PRESS AND CIRCULAR of the 9th January, 1867, will be rendered more complete and correct by the addition of the following information, which, as a Corkonian, interested in upholding the character and fame of my native city, I take great pleasure in publishing.

Dr. John Milner Barry, of Tunbridge Wells, having discovered that I was not in possession of the history of the early introduction of vaccination into Cork, in a letter dated 22nd January, 1867, kindly writes as follows:—"In your instructive paper on the 'History of Vaccination,' in THE MEDICAL PRESS AND CIRCULAR of January 9th, 1867, you have not referred to the early history and to the introduction of vaccination into the City of Cork, which is the more remarkable, as the 'Beautiful City' received this boon at an earlier date than any other city or town in Ireland. 'Vaccine inoculation' was introduced into Cork in June, 1800, by the late Dr. Milner Barry, and between that date and November 20th, 1800, upwards of two hundred persons had been successfully vaccinated. For proof I refer you to a pamphlet published by him, a copy of which you will find in the Royal Cork Institution. There is a copy also in the Library of the Royal Medico-Chirurgical Society of London. As a native of Cork, and the son of the author of this pamphlet, I take much interest in everything relating to the introduction and spread of vaccination in Cork." This pamphlet, Dr. Caulfield, Librarian to the Royal Cork Institution, kindly hunted out for me a few days ago—here is a copy of the title-page—"An Account of the Nature and Effects of the Cow-Pock, illustrated with cases and communications on the subject; addressed principally to parents with a view to promote the extirpation of the small-pox. By John Milner Barry, M.D. Cork: Printed by M. Harris, Castle-street, 1800."

It is dedicated as follows:—

"To Dr. Longfield.

"DEAR SIR,—If the inoculation of the cow-pock has already made some progress in this City, it is principally due to the early proof you gave of your belief in its efficacy, by the inocu-

lation of your grandson. This is sufficient reason for dedicating the following pages to you; permit me, at the same time, to express publicly the deep sense I entertain of your personal kindness, and my admiration of the extent and variety of your philosophical and professional knowledge.—I have the honour to be, dear sir, your sincere, humble servant, J. M. BARRY.

"Tuckey-street, Nov. 20, 1800."

The author concludes a paragraph, page 3, thus:—"If by the following account, in which the reports of the best writers have been confirmed by my own observations, I contribute to extend a medical practice which must, ultimately, banish from the earth a disease highly destructive to human happiness, I shall think myself sufficiently recompensed." Again, at page 15, he writes:—"The vaccine matter which I first used was sent me on a silk thread by Dr. Bradley, of London. On the 6th June, eight days after the infection had been taken in London, I inoculated six children by raising the skin with a lancet, and inserting a bit of the silk, which I then secured with a little sticking-plaster. In three the inoculation succeeded, from whence I procured an abundance of the infection, with which I inoculated a number of children in the city and its neighbourhood. Not long after I received a second thread from Dr. Pearson, physician to the Cow-Pock Institution in London; with this thread Dr. Sugrue inoculated several children at the north end of the town."

The following being of local interest, I am induced to copy in detail from the pamphlet, as when seen it cannot but interest some of the living relatives, and put them in possession of facts with relation to their ancestors, probably hitherto unknown to them:—

### CASES OF PERSONS INOCULATED WITH VARIOLOUS MATTER, WITHOUT EFFECT, AFTER HAVING HAD THE COW-POCK.

1. R. Radcliffe, aged two years, } sons of Mr. Radcliffe,
2. J. Radcliffe, aged two months, } Henry-street.
3. — Supple, aged two years, daughter of Mr. Supple, Fishamble-lane.
4. Ann Notter, aged five months, daughter of Mr. Notter, St. Patrick's-street.
5. Peter Rearden, aged one and a-half years, son of Mr. Rearden, St. Patrick's-street.
6. William Kennedy, aged nineteen years, servant to the Rev. Giles Lee.
7. A Negro Girl, aged eighteen years, servant to Mr. Smith, Nile-street.
8. — Cowen, aged four months, daughter of Mr. Cowen, Attorney.
9. — Broughton, aged two years, son to Mr. Broughton, Nile-street.
10. Ellen Barry, aged two years, son to Mr. Barry, Mallow-lane.
11. Judith Herrick, aged six months, daughter to Mr. Herrick, Currahaly.
12. William Gregg, aged two years, son to Mr. Gregg, Attorney.
13. M. Campion, aged six months, daughter to Mr. Campion, Dromore.

Dr. Sugrue inoculated two children of Mr. Montjoy's, Kyrils-quay, and two of Mr. Hayes', North Main-street.

A paragraph, page 27, says:—"In pregnancy, the almost absolute certainty with which abortion follows the small-pox, and the consequent danger to life, have deterred practitioners from inoculating pregnant women; but even in the advanced stage of pregnancy women have been inoculated for the cow-pock with perfect safety to themselves and their offspring. Of this, I had myself one example. A woman six months gone with child, having the small-pox raging in the neighbourhood, as she had recent instances of its mortality in her own family, applied to me to be inoculated with the cow-pock; she took the infection, and passed through the disease without any accident—the symptoms proving as mild as possible.

On page 42 you may read—"The natural cow-pock was universally known among our farmers by the name of *shinach*."

The pamphlet is a very interesting one, and now, after

seventy years' experience, proves the soundness of the author's views. I feel personally indebted to Dr. Barry for calling my attention to this pamphlet, a production of which, as a native of Cork, and the son of the author, he must feel naturally proud, and I don't wonder at his wish to guard it with jealous care. It may be found in a book of pamphlets printed by Edwards and Savage, Cork, 1821, and in the possession of the Royal Cork Institution. When now turning over its leaves, I find an article headed "Cow-pock," on page 20—no author's name—at foot of which I read the following paragraph:—"If there are any medical gentlemen in this town who continue still to entertain serious doubts on this subject [there are none in 1867], I verily believe they must arise from want of sufficient experience. To such gentlemen my friend Dr. Bullen, whose affection for his children is unquestionable, makes the following offer—Two of his children passed through the cow-pock some months since, whom he is prepared to submit to any ordeal these gentlemen may devise for communicating the small-pox to them." There is no date to this article. The offer was a bold one. The author must be Dr Barry.

## Hospital Reports.

### RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

#### Dr. LYONS'S CLINIQUE.

(Reported by Dr. BELCHER.)

#### RHEUMATIC ARTHRITIS.

C. D., an unmarried female domestic servant, aged 28, was eight days an intern patient at the Whitworth Hospital at the date of this report (March 6th), and had been four days ill previously to her admission. Dr. Lyons considered her case to be one of rheumatic arthritis. At the date of this report her pulse was quiet; and the disease, which had been found to affect the wrists, knees, ankles, shoulders, and hips, had entirely subsided. The mode of treatment adopted by Dr. Lyons in this case is worthy of note; not because of any originality in the means employed, which are mostly well-known and popular remedies, but in their combination, and as illustrating the rationale of a plan at once useful and easy of application.

In the first instance the patient was encased in a flannel jacket with the view of keeping up an uniform temperature in the body, and with the same object the sheets were removed from the bed, and the patient was made to lie literally "between the blankets."

In the next place the affected joints were poulticed with a mash of chamomile flowers and poppy heads.

In the third place she took a quarter of a grain of opium every four hours; and, at the same time, she was ordered a combination of three salts of potass, half an ounce of the bicarbonate, and two drachms each of the nitrate and acetate, in seven ounces of infusion of calumba, and an ounce of tincture of gentian; half an ounce of this mixture every three hours.

The rationale of this treatment may be shortly explained thus: the bicarbonate saturates the uric acid, and makes a soluble salt, which is washed out of the system through the kidneys under the stimulus of the acetate and nitrate. The warm poultices give immediate and permanent ease, and retain the deposit in the joints until it is taken up in the soluble form, thus preventing any repellent action which, by metastasis, would tend to drive the inflammation to the heart. The opium procures sleep, and gives great relief from pain, the patients passing through the disease with little or no suffering.

This plan has been extensively used by Dr. Lyons, and with, as he conceives, the effect of speedy relief to the sufferings of the patients so treated; and also with the important effect of a very large proportionate immunity

as regards the principal organ, the heart, less than one in twenty of such cases having presented cardiac complications. During the last twelve months Dr. Lyons has treated on this plan about twenty-five such cases in this hospital.

As regards the subject of the present report, it may further be stated that she got complete and permanent relief in six days after admission; and it may also be noted that at the time of her admission to hospital she had slight cardiac irritability, on account of which the method of treatment by anticipation was adopted, and two leeches were applied over the region of the heart, followed by poultices. This method had the desired result, and no trace of cardiac murmur is now audible.

#### STRUMOUS OPHTHALMIA, AND ENLARGED SPLEEN, SPLENIC MURMUR.

R. T., a boy aged 15, was admitted under the care of Dr. Lyons on the 30th January, 1867. He had then double strumous ophthalmia, but the principal feature in his case was an enormous enlargement of the spleen, which was readily perceptible on palpation, forward as far as the linea alba, and downwards as far as the crest of the ilium. In the course of a careful clinical examination, it was observed by Mr. G. Martyn, a pupil of Dr. Lyons, that there was a well marked *soft souffle*, audible over the splenic tumour, the cardiac sounds being at the same time perfectly normal, and devoid of all character of murmur. The murmur continues at the date of this report, (6th March), and has been recognised by many visitors to these wards. In Dr. Lyons's view, this case is interesting as affording a rare stethoscopic phenomenon, and, as he suggests, it may prove useful in establishing a diagnosis between enlarged spleen, and a tumour of any other kind occupying the situation of that organ.

As regards treatment, the patient has been taking cod liver oil, and also the syrup of the three phosphates which we brought before the profession last year in these reports, as recommended and used by Dr. Lyons, and which we are glad to find has been frequently noticed in favourable terms in various home, colonial, and foreign medical journals, since we had the pleasure to introduce it, and other remedies recommended, and in point of fact invented by this gentleman, to the notice of the profession. The chlorate of quina is another instance in point.

#### INCIPIENT PARALYSIS, AND SLOW SPEECH.

P. C., aged 33, a tavern waiter, of very intemperate habits, and who was more than once under treatment for delirium tremens, was under the care of Dr. Lyons at the Whitworth Hospital at the date of this report, (6th March). The patient stated that six months ago he fell in the street, and was carried home insensible, since that time he exhibited symptoms of a very slight amount of advancing cross paralysis. There was very slight traction of the right cheek to the left side, and perceptible, but very slight loss of muscular power in the left upper extremity, and left leg, which, as he says, "has a slight kick in it."

Dr. Lyons is of opinion that the lesion in this case is probably in the right hemisphere, and most probably in the corpus striatum. It will be interesting to follow the clinical history of a case presenting in its incipient condition the phenomena of ordinary paralysis.

The treatment was tonic, with half grain doses of nuxvomica, thrice daily.

### ST. GEORGE'S HOSPITAL.

#### EXTRACTS FROM A LECTURE BY DR. OGLE.

AFTER dwelling upon the phenomena of "collapse," and alluding to the various affections in which it was wont to occur, Dr. Ogle instanced the two following cases as examples of extreme collapse accompanied by symptoms leading to the belief that the patients were suffering from cholera; of these two cases the first was particularly inter-

esting, in as much as it occurred at a period when cholera was beginning to increase in London, that is in the middle of last year, a circumstance which of course at the time lent great force to the suspicion that the patient was the subject of this malady.

DIARRHŒA AND VOMITING; ARREST OF THE FUNCTIONS OF THE KIDNEYS; SYMPTOMS OF COLLAPSE; ABSCESS IN THE PERINEUM; EVACUATION OF PUS INTO THE BLADDER; STRICTURE OF THE URETHRA (DOUBLE); CONGESTION OF THE LUNGS AND KIDNEYS.

*Case 1.* The patient, a coachman aged 47, was admitted in June 5th last, under Mr. Tatum's care, with difficulty in passing the urine, and with a fluctuating swelling in the perineum. For ten years he had suffered from stricture. The abscess was opened; ordinary diet and porter were given, and morphia at bed time. Ten days after admission the wound was quite healed, and a No. 5 gum catheter passed. Three days later a catheter could not be got into the bladder, and on the same day he had three or four rigors, followed by burning heat, and by a sleepless night. On the next day the tongue was dry and furred, the bowels relaxed, the respiration hurried, and the pulse hardly to be felt at the wrist. Hot brandy and water and strong beef-tea were given, and ten drops of the liquor opii sedative every four hours. In the afternoon of this day (the 20th) Dr. Ogle saw the patient with Mr. Tatum. No urine had been passed all day. There was hiccough, and the skin was covered by cold perspiration, the pulse was almost imperceptible, the breath diminished in temperature. Everything taken was vomited, and, in the evening, still no urine had been passed. The stools were yellow, slimy, and rather offensive. No pain was felt, but the patients general condition very much resembled that of a cholera patient. Hot bottles and mustard poultices were applied to the body, and ammonia, opium, and hydrocyanic acid given. On the 21st the face and extremities had become quite blue. The tongue was pale, coated with a yellowish brown fur, the pulse quite gone, and the heart's sounds inaudible. The mind occasionally wandered. The temperature of the body was very low. A gum catheter was passed, and about one oz. of purulent urine was drawn off. No urine had been passed voluntarily. In spite of brandy and æther, &c., he died in the afternoon of the same day.

On *post-mortem examination* the brain was found much congested with black blood, but otherwise it was healthy. The left lung was congested. The heart was uncontracted, containing black, fluid blood; the valves being blood-stained. The kidneys were congested, but otherwise healthy; as were the spleen and liver. The urinary bladder was much thickened, and the surrounding structure hypertrophied. In front of the prostate gland, and opening into the urethra, just at the neck of the bladder, was a large abscess; and the pus from this abscess had evidently run backwards into the bladder, which contained about two ounces of thick, laudable pus. In front of the membranous portion of the urethra was a tight stricture, admitting only a small director, and in front of this a false passage. Near the urethra was also another stricture. Excepting a small fibroplastic tumour in the walls of the stomach, this organ and the intestines were healthy. (See P.-M. B., 1854. No. 214.)

VOMITING AND DIARRHŒA: SYMPTOMS OF EXTREME COLLAPSE: PERFORATION OF THE STOMACH, &c.

*Case 2.*—Anne C., aged 21, was admitted July 26, 1854, in a very emaciated state, with constant vomiting, she had not menstruated for six months, and had had pleurisy nine weeks before admission. After her admission the sickness did not appear for some days, and then only occasionally, and about a quarter of an hour after food. On the 19th she had diarrhœa, and in the evening, when returning from the water-closet, she fell down in what was called a "fainting fit." Soon afterwards her face became dusky, and the features were pinched and sunken. She was quite pulseless. By the aid of stimulants she rallied at eight p.m., and took a scruple of calomel and had a mustard emetic,

afterwards two grains of calomel were given every two hours, with a draught containing sulph. magn. and carb. soda. She was shortly afterwards taken with cramps, continued purging of rice water stools, and her face appeared of a livid hue. She sunk and died soon after mid-day on the 20th.

On *post-mortem examination* by Dr. Ogle, the nails of the hands were very livid; the lungs contained much frothy fluid, but were otherwise natural; the texture of the heart was very weak, and its right cavities and left auricle contained weak clotted blood; the left ventricle being empty and slightly contracted. The peritoneal surface of the bowels was pale; the inner surface of part of the ilium and duodenum was very vascular, and some of the intestinal glands, ilium, and colon were enlarged. The mesenteric glands were enlarged. The pyloric end of the stomach was congested, and its walls much thickened and hardened, and at one part presented a rounded ulcer, perforating its walls and only blocked up by an adherent fold of peritoneum (part of the omentum). On examining the thickened submucous tissue of the pylorus it was found *microscopically* to contain large quantities of coarse fibrous tissue mixed with fusiform elongated cells.

Dr. Ogle then referred to the following case which occurred in his out-patient practice, and is interesting, as presenting a phenomenon (hiccough) not often met with in cases of phthisis pulmonalis. Dr. Ogle suggested that the symptom might have been the result of adhesion of the lung to the diaphragm, by which in some way or other this muscle or some branches of the phrenic nerve were irritated:

PERSISTENT AND PAINFUL HICCOUGHING; PHTHISIS PULMONALIS; VOMICA; PNEUMOTHORAX; ADHESION OF LUNG TO THE DIAPHRAGM.

*Case 3.*—The patient, a horse-breaker, Walter M., aged 24, came under Dr. Ogle's care as an out-patient, April 13th, 1866, suffering from distressing hiccough, which he had had for thirteen days, as he said, night and day; this had come on quite suddenly after drinking ale and porter, which he vomited. He stated that he had an attack of a like kind for one day and a night four or six years previously when at Abergavenny, and he was attended by Dr. Smythe for bronchitis. In the present attack he had managed to stay the hiccough for a period varying from a quarter of an hour to an hour at a time by taking a cup of hot tea, and on the day before admission for seven hours by some medicine which had been given to him. He was evidently very distressed from want of rest and sleep, and, moreover, was in an advanced stage of pulmonary consumption. He observed that the hiccough was "just wearing him out." His tongue was very furred, and he was feverish; an opium linctus was prescribed, and a powder containing bismuth and magnesia. It appeared that the hiccough went on for four days and then ceased. On the 20th Dr. Ogle made him an in-patient, and he was admitted under Dr. Fuller's care. He died May 2nd.

On *post-mortem examination* much tubercular matter was found in the lungs, and a vomica at the apex of the right one. Bands of recent lymph connected the lower part of the right lung to the diaphragm, as well as the thoracic parietes, and about from two to three pints of fluid existed at the bottom of the right pleural cavity, in which the lung lay quite collapsed; and above this the pleural cavity formed a sac in which air was contained which had escaped apparently from the vomica above-noted. (See P.-M. B., 1866. No. 134.)

### PHYMOSIS.

Under the care of Mr. LEE.

[Reported by Mr. E. C. RING, Surgical Registrar.]

Thos. E., æt. 8, was admitted on June 26th, under the care of Mr. H. Lee, with phymosis, the prepuce being greatly distended, swollen, and lengthened; there was a good deal of pain. On July 3rd the swelling had greatly diminished, and there was an ulcerated crack on the under

surface of the penis, just in front of the scrotum. This soon became a fistulous opening, and the urine passed both through it and the meatus urinarius. On the 28th he was discharged for a time. He was re-admitted on August 16th, and on the 23rd the edges of the orifice were pared, and brought together from before backwards with silver sutures, the prepuce at the same time being slit up on the dorsal surface. A catheter was passed and tied in; the urine escaped entirely through the instrument, which was withdrawn on the 9th of September, the wound having entirely healed, a perfect cure being thus effected.

## Parliamentary Intelligence.

### HOUSE OF COMMONS.

MARCH 6TH.

#### SANITARY STATE OF HOLYHEAD.

MR. WALPOLE, in reply to Mr. O. Stanley, said that Dr. Buchanan's report of the sanitary state of Holyhead would be published in the Report of the Medical Department of the Privy Council, and need not, therefore, be printed separately.

#### CHOLERA.

In reply to Sir J. C. Jervoise, Mr. WALPOLE said he could not undertake to say whether Dr. Frankland's report on cholera-stuff (choline) was scientifically true. The Registrar-General had published it in his appendix to his Weekly Return, believing it to be a valuable document, emanating as it did from so high an authority as Dr. Frankland, and as tending to put the public on their guard in dealing with what were supposed to be cholera cases. He was not aware that the Government intended to introduce any Bill on the subject.

Sir J. C. JERVOISE asked the Vice-President of the Committee of Council on Education whether his attention had been called to the report of the medical officer of the Privy Council, (1866), in which he states, pp. 39-40, the mode in which cholera-contagium is generated; whether the discoverer has divulged his method of obtaining this deadly agent; and, if not, why not; and whether the annual report of the medical officer, which was not accessible to members till towards the end of July in the last, will be so at an early period of this session.

MR. CORRY said the statement referred to was not due to any single discoverer, but was the result of scientific investigation by many competent authorities. With regard to the annual report, a great deal of extra labour had been cast upon the medical officer by the cholera outbreak of last summer, and he could not, therefore, hold out the expectation that it would be presented much earlier than it was last year.

MARCH 8TH.

#### METROPOLITAN POOR BILL.

The House went into Committee on this Bill.

Clauses 1 to 4 were agreed to.

On Clause 5, relating to the provision of district asylums,

MR. MILL objected that the management of every separate asylum should be under a separate body, and that every dispensary should be under a different management. He was in favour of the administration of the same kind of things, as far as possible, on a large scale. A central board would be more under the eyes of the public. With a central board in existence the duties of the vestries would be those of superintendence rather than of execution. Administrative duties were best developed by a single hand, which should be responsible, and, if possible, paid; and the executive administration of the Poor-law Board should devolve on paid officers, who would be watched in the districts by the vestries, which would consist of ready-made critics superintending others with a vigilance with which they did not like others to superintend them. In this way an addition might be made to the provisions of

this Bill for securing appropriate superintendents. The proposal to make the asylums medical schools, and thus to secure them the constant supervision of skilled persons, did the greatest credit to its author, and was a proof of high legislative capacity.

MR. HARDY said that great difficulties existed in making an entire change in the present system. It was very different from organising an entirely new system. He had kept in view progress in those matters, but he thought it wise to proceed step by step. Dispensaries would remain in the hands of Boards of Guardians, who had not been objected to as administrators of out-door relief. The dispensaries would differ from the hospitals in being restricted to the relief of out-door poor, and for that reason he thought it prudent to leave them, as they were in Ireland, under the care of dispensary committees of the Board of Guardians. He was glad Mr. Mill approved making asylums medical schools, a plan which had been formerly adopted at Marylebone Workhouse, and had acted most beneficially in Ireland.

MR. VILLIERS could not see any provision in the Bill for making a single board control all those asylums for the sick poor. He objected to the word "asylum," and suggested the substitution of "hospital," or the words, "places where the sick poor shall be relieved."

Sir H. VERNEY also objected to the term asylums.

MR. AYRTON and Sir W. RIDLEY thought the word "asylum" as good as any other, and Mr. Alderman LAWRENCE thought it "a most unfortunate word."

MR. HARDY would not say anything about the word "asylum." The object of the clause was to give the Poor-law Board the necessary powers to classify the whole order of paupers, and to that end it was essential that the words proposed to be omitted should be retained in the clause.

After a lengthened discussion on an amendment of Mr. CHAMBERS, that all the managers should be elected, and which was negatived by a large majority,

DR. VANDERBYL moved an amendment to the effect that the medical officers should be members of the Board, without power of voting.

EARL GROSVENOR approved the amendment, which would do away with the necessity of medical officers, who were educated men, being compelled to knock their heels outside the Board-room while questions of interest to them, and in the discussion of which they were well qualified to take a part, were being considered within.

Colonel HOGG said the ratepayers could now, if they thought it desirable, elect medical men as guardians, and often did so; and it would be adopting a new principle, and one which in his opinion would not work at all well, if the Committee agreed to the amendment. When questions were discussed in which the advice of the medical officer was advantageous, that officer was generally requested to appear before the Board and give his opinion, and if that course were not adopted on such occasions the guardians would fail to perform their duty.

MR. AYRTON said it was often desirable to have the medical officer's opinion in writing for the guidance of the Board; but if that officer became a member, even without the power of voting, he would not only be oftentimes placed in a false position, but his efficiency would frequently be destroyed.

MR. VILLIERS thought that the presence of the medical officers on the Board would be of great advantage.

DR. BRADY approved the amendment.

MR. HANKEY thought that the attendance of medical officers at the Board would only be a waste of their time.

MR. HARDY objected to the amendment, on the ground that it would place the medical men in a false position.

The amendment was then negatived without a division, and the clause was agreed to, and added to the Bill.

MARCH 11TH.

The debate on the Metropolitan Poor-law Bill was resumed.

MR. VANDERBYL proposed in Clause 42, instead of the words "proper persons" for the dispensers of medicine, the

following: "Persons on the Medical Register or duly certified as competent under the provisions of the Pharmacy Act of 1852, or the Apothecaries' Act of 1815."

After some discussion, in which Dr. Brady, Mr. Gilpin, and others took part, the amendment, on the suggestion of Mr. HARDY, was withdrawn, the word "qualifications" being put a little lower down in the clause, the effect of which would be to bring the matter under the supervision of the Poor-law Board.

After a short conversation respecting Clause 43, the words "entitled to," instead of "in receipt of," were substituted.

On Clause 45, Mr. MILL suggested that Poor-law medical officers should not be in private practice, but devote their services entirely to the poor; and further suggested that the Colleges of Physicians and Surgeons, in conjunction with the Civil Service Commissioners, should frame a system of competitive examinations for the purpose of testing the fitness of Poor-law medical officers. Mr. Mill did not move an amendment.

Mr. HARDY did not think medical men could be got to undertake the duties of Poor-law officers without the option of private practice as well. In London, in some instances, practitioners had found private practice incompatible with their public duties, and have given it up. But, speaking generally, the salaries were so small that it would not be possible to obtain properly qualified men without private practice. He was not prepared to give his adhesion, at the present moment, to the system of competitive examinations.

Dr. BRADY opposed the competitive examinations, and eulogised the profession for their gratuitous services to the poor on all occasions.

On Clause 59, Mr. NEATE inquired what was the basis of compensation, if, for instance, the Board might appoint an indoor for an outdoor medical attendant.

Mr. MILL said the clause as it stood gave such power to the Board as left the present medical officer at the mercy or discretion of a single officer.

Mr. HARDY would retain the clause, which had been long before the house and no objection made to it. Compensation would be made in accordance with, and calculated upon, the terms of the contracts. There would be no difficulty at arriving at a right decision in any case.

On Clause 67, Earl GROSVENOR moved an amendment which would have had the effect of transferring to the common fund all expenses connected with providing the necessary asylums for the working of the Act.

Some discussion took place on the amendment, in which Mr. Ayrton, Mr. Hardy, Mr. Goschen, Mr. Locke, and Sir H. Verney took part. The amendment was lost on division by 35 to 97.

Sir H. VERNEY rose to move the addition to the clause, at page 14, after line 31, of the following words:—"For the maintenance in a sufficient number of duly regulated hospitals, and under the care of trained nurses, of the sick poor, together with the cost of training nurses."

After some discussion this amendment was negatived, as was one by Earl Grosvenor in section 2 to insert after "small-pox" "cancer and syphilis."

Mr. P. WYNDHAM moved the insertion after Clause 28 that "asylums be provided with hospital carriages of such a pattern as the Poor-law Board shall approve of for the conveyance of persons suffering from small-pox, fever, or other infectious disease."

Mr. G. HARDY said this was already provided for by the clause under the words "other conveniences."

The preamble of the Bill having been agreed to, it was ordered to be reported.

**LONDON HOSPITAL.**—On Wednesday evening, March 13th, a dinner was given at the London Tavern by the members of the Medical and Surgical Staff and the Resident Officers to Dr. James Jackson, the late Resident Medical Officer, who is about to leave for Australia. The chair was occupied by Mr. Little, and amongst those present we may mention—Drs. Hughlings Jackson, Morell Mackenzie, Sutton; Messrs. Couper, Rivington, James Adams, &c.

## Reviews.

**ST. GEORGE'S HOSPITAL REPORTS.** Edited by JOHN W. OGLE, M.D., F.R.C.P., and TIMOTHY HOLMES, F.R.C.S. Vol. I. 1866. Pp. 444. London: Churchill and Sons.

In imitation of the example set by Guy's Hospital, the medical staff of St. George's have issued the first volume of a series of reports which, it is contemplated, will be annually continued. The present volume promises well, and forms a handsome book, and that the arrangement and selection of the contents will be efficiently carried out is amply guaranteed by the names of the editors, Dr. Ogle and Mr. T. Holmes. The papers are twenty-two in number, and are almost entirely written by the medical staff of the hospital and the lecturers in the medical school. The work, we are told in the preface, was originally designed mainly as a means of registering the experience gained in the hospital, and independently of the papers, which, with one exception, are on practical medicine and surgery, there are complete reports by the medical and surgical registrars, relating the results of all the cases which have received treatment in the wards of the hospital during the course of the year 1865.

The first paper, which we have alluded to as offering an exception to the practical character exhibited by the rest, is, nevertheless, a very interesting one, being devoted to a compendious history of the St. George's Hospital and School, and not only the past and present pupils of the hospital will read the account with interest, but the whole profession will be gratified by tracing the gradual progress of the institution from its suburban and comparatively insignificant position a hundred years ago to its present permanent, spacious, and pretentious dimensions, which are, we understand, to be further extended in connexion with other improvements in the vicinity. The history of the school also, springing as it did from the indignant remonstrances of John Hunter against the neglect of some of his colleagues in not giving clinical instruction to the pupils, is a curious episode in the advancement of medicine and surgery; the struggles of a few of the medical staff, John Hunter among the first, having gradually overcome the opposition of their colleagues and the apathy of the governors, until the utility of medical teaching was, as it is now, fully recognized, and the means for its practical development were adequately but not yet liberally supplied.

The other papers, as we have before observed, are all of a practical character, and comprise contributions to the Surgery of the Head, by Mr. Prescott Hewett; a case of Meningocele in the Occipital Region, injected with Iodine, without ill consequences, by Mr. T. Holmes; Remarks on the Typhus Epidemic of 1864-5, as observed in St. George's Hospital, by Dr. R. E. Thompson; Remarks on Progressive Locomotor Ataxy, by Mr. J. Lockhart Clarke; some Observations on Cerebral Symptoms occurring in certain Affections of the Ear, by the late Mr. Toynbee; some Practical Details on Amputation at the Hip-joint, and on the Applicability of this Operation to some of the worst cases of Morbus Coxarius, by Mr. T. Holmes; a case of Disease of the Brain, illustrating the Cerebral Lesions resulting from Diabetes Mellitus, by Dr. J. W. Ogle; and others by Dr. Bence Jones, Mr. Brodhurst, Dr. Dickinson, Dr. W. Ogle, Mr. George Pollock, and Mr. E. Naylor.

### THE ACTION OF MEDICINES IN THE SYSTEM.

By FREDERICK WILLIAM HEADLAND, M.D., B.A., F.L.S. Fourth edition, revised and enlarged. Pp. 449. London: Churchill and Sons. 1867.

THIS work of Dr. Headland has gradually expanded from the dimensions of an essay, in which form it first appeared when it received the Fothergillian Medal of the Medical Society of London, into the goodly volume now before us; but the present edition, while it has been improved and amplified, has not been inconveniently enlarged, as compared with the last edition. Since the period of the publication of the original essay, what a multitude of observation has been made upon the action of medicines in general and in particular, is well known to those who are conversant with medical literature, and while, on the one hand, innumerable additions have been made to the catalogue of existing remedies, or supposed remedies, on the other hand the efficacy of most medicines has been in more than one influential quarter strenuously denied. As to these drugs again, the activity of which is undoubted, the most conflicting views have been advocated with regard to their *modus operandi*, and their efficacy in particular diseases. Amidst

such a diversity of opinion, and in the face of so much scepticism and of so much credulity, it is consolatory to turn to the pages of such books as that of Dr. Headland, where the real position of medicines is fairly stated, and their operation, either individually or in groups, is carefully defined. We can perhaps give no higher praise to Dr. Headland's volume than to state that it is a learned and thoughtful summary of the present state of therapeutics, and that it may be consulted with safety and advantage by all who would wish to make themselves acquainted with the present received views of the action of medicines on the human system.

**ST. BARTHOLOMEW'S HOSPITAL REPORTS.** Edited by Dr. EDWARDS and Mr. CALLENDER. Vol. II. Pp. 264. London: Longmans. 1866.

THE excellent plan of making the experience of our great hospitals available for the general information of the profession cannot be too highly commended or too liberally encouraged, and we are glad to perceive by the published lists of subscribers appended to each of the volumes of Hospital Reports hitherto presented, that the objects held in view by the promoters are liberally seconded by the former students of the respective institutions. The present volume of St. Bartholomew's Hospital Reports, although not so bulky as some of its rivals, contains a great variety of valuable materials, most of which, as is usual in such reports, are of a practical character, and are derived from the personal experience of the writers of the respective papers. The last article in the number consists of extracts from the Statistical Report of the Hospital for the year 1865, and contains a series of tables selected for republication from the Annual Report of the Registrars of the Hospital, Dr. Edwards and Mr. Willett. These tables show the whole number of medical and surgical cases received into the hospital during the year, the names of the diseases, the results, the mean duration in hospital, and other particulars; but the editors point particularly to some of the tables which show the number of cases of disease bred within the walls of the institution, thus adding unduly to the mortality. It should be mentioned, however, that all the cases of erysipelas, or fever, or pyæmia, returned as supervening upon other diseases, are not generated within the hospital, but many of the patients are charged with the disease on their admission, and it develops itself when they are recovering from the accident or injury for which they have been treated. Among the contributors of papers are to be found the names of most of the staff of the hospital, including Mr. Savory, Mr. Paget, Mr. Callender, Mr. Holmes Coote, Mr. Luther Holden, Dr. Edwards, Dr. Duckworth, and Dr. Farre.

**PROPOSITION FOR A NEW REFORM BILL, TO FAIRLY REPRESENT THE INTERESTS OF THE PEOPLE.** By W. F. STANLEY. London. 1867.

REFORM Bills do not lie much in our way, though we should gladly hail a bill which would admit of our profession being represented in Parliament. Mr. Stanley would not allow any one class to legislate for us all; and, moreover, he would have fifty members representing "learned societies," our profession included. We do not think it at all likely that Mr. Stanley's proposition will become law, this session at least.

**PRACTICAL OBSERVATIONS ON THE INTELLECTUAL, SANITARY, AND MEDICAL TREATMENT OF THE DEAF AND DUMB.** By HENRY SAMUEL PURDON, M.D., &c. Belfast. Pp. 95. 8vo.

THERE is not any date prefixed to the publication of this tractate, which, judging from internal evidence, we should say was printed in 1866. It comprises an introduction, seven chapters, and a conclusion; and contains very much that is interesting, besides a large amount of statistical information of considerable value to our profession.

**THE MODERN TREATMENT OF PNEUMONIA IN YOUNG CHILDREN, WITH SOME OBSERVATIONS ON THE INITIAL AUSCULTATORY SIGN OF THE DISEASE.** By G. STEVENSON SMITH, L.R.C.S.E., &c. Pamphlet. Edinburgh: 1866.

THIS pamphlet is a reprint from the *Edinburgh Medical Journal* for November, 1866, in a notice of which periodical we duly mentioned the paper now before us.

Mr. Stevenson Smith treats simple uncomplicated pneumo-

nia in the young child on much the same plan as that known in connexion with the name of Dr. Hughes Bennett; and, according to the statistics here furnished, with the same successful result. "Dr. Bennett," remarks the author, "has shown by statistics, the accuracy of which no amount of quibbling can affect, that in the adult, uncomplicated pneumonia, when treated according to what he calls the restorative plan, almost always ends in recovery."

**CASES OF POSTURAL TREATMENT IN PROLAPSE OF THE FUNIS.** By ROBERT DYCE, M.D., F.R.S., Edinburgh. Professor of Midwifery, Aberdeen. Pamphlet.

THIS pamphlet is a reprint from the *Medical Times and Gazette* of November, 1866, and is well worth the reading of obstetricians. The well-known name and position of Dr. Dyce is sufficient guarantee for the value of any paper bearing his name on its title-page.

**LECTURES ON PUBLIC HEALTH.** By E. D. MAPOTHER, M.D. Dublin: Fannin and Co. London: Longman and Co. 1867.

THESE lectures seem considerably enlarged in their re-issue, and we may say are almost entirely re-written. The author says in his preface that the first lecture is scarcely altered, but that the others which were included in the first edition, have been enlarged, and twelve new ones have been added. Dr. Mapother's views in bringing out a new edition of this really useful book, is to bring before the public his experience gained from the late visitation of cholera. Under these circumstances the book will be read with considerable interest.

The author commences with a review of the sanitary state of Dublin in 1864, the date when this book first appeared. He then proceeds to the consideration of air, including its impurities, and the principles of proper ventilation. From this subject we are led to consider food in its various phases, and then baths and clothing. Two chapters are devoted to sanitary architecture, viz.:—Hospitals, dwellings of the labouring classes, &c. Dr. Mapother is decidedly a well-read man upon the subject upon which he is writing; this fact is particularly evinced in this part of his own work, as few authorities or writers on his subject escape his notice.

The prevention of zymotic and constitutional diseases; the cholera in 1866; the cattle plague; disinfection, &c., are the subjects of additional lectures.

It is probably to lecture xviii. (one of some length) that the reader will look with much interest, as it is chiefly taken up with the consideration of the outbreak of 1866. There is no one more authorized to write upon this outbreak, as it occurred in the City of Dublin, and few who, with the most unremitting attention during its prevalence, would be able to gain such an insight into this mysterious disease as Dr. Mapother. That gentleman is a contagionist, he says:—"I will use the words 'contagious' and 'infectious,' in no limited sense relating to touch or air alone, but as synonymous with 'communicable,' or the familiar word catching."

"The Contagiousness or non-contagiousness of cholera has been warmly debated since that disease left 'its home' in 1817. The ablest men in our profession have been ranged on one side or the other, and victory seems to have vibrated between the disputants.

"In 1832 all were contagionists; in 1849 nearly all held the contrary opinion, and after 1866 a medium view will be established."

No one who reads Dr. Mapother's graphic account, or has had any practical experience himself, can hold very opposite views from those expressed in this chapter. Each unfortunate return of the epidemic makes us better acquainted with its modes of extension, even if no better knowledge is gained.

The latter part of the work is taken up with legislature enactments bearing upon hygiene, and contains some useful suggestions.

Although these lectures are addressed to a medical body (i.e., they were delivered at the Royal College of Surgeons), they are written in a popular form, Dr. Mapother having adopted the style so freely made use of by Dr. Lankaster, Professor Johnston, and a few others. By such means the author constructs a book which, although ostensibly written for the scientific man, will, no doubt, be largely bought by the ordinary reading public. Some of the illustrations might be better; indeed, we think, that in any future edition this book is too good not to appear in a better dress.

### NEW POOR-LAW BILL FOR LONDON.

MR. GATHORNE HARDY'S first appearance as a Poor-law Reformer has been eminently successful, for his Metropolitan Poor Bill has passed through all its stages in the House of Commons, and by the time that our journal is published, it may possibly have become the law of the land. But whether this be so or not, it is evident that the measure has been received with general satisfaction, and its ultimate adoption may be looked for with certainty.

It is satisfactory to find that the public and the House of Commons have not been alarmed by the bugbear of centralization, and thereby induced to obstruct the Bill in consequence of the power which it is proposed to transfer from the local guardians to the Poor-law Board. It has been shown repeatedly that the local guardians, however respectable they may be in a private capacity, are totally unable to regulate the management of the sick poor nominally intrusted to their charge; and that harshness to the unhappy patients and ill-treatment of the Medical Officers are the rule rather than the exception in Parish and Union government. The whole energy of the guardians and trustees has been expended upon the labour of reducing the rates, and the cruel plan has been consistently pursued of jumbling together under one roof, and often in the same wards, the sick and the healthy, the dirty and the clean, the sane and the lunatic; and all the efforts of the Medical Officers to improve the condition of the sick and infirm have been met with apathy, obstruction, opposition, insult, or dismissal. The Poor-law Board itself has a heavy incrimination of its own negligence to answer at the bar of public opinion; it has to explain why its well-paid inspectors have flagrantly neglected their duty, and (*lucus a non lucendo*) have thought that they are best discharging their functions by shutting their eyes to the abuses which they witnessed. We have asserted, and we re-assert, that the Board knew perfectly well of many of the atrocities, in the way of mismanage-

ment of the sick poor, which were committed by the local guardians; but on the principle of *quieta non movere*, and because the Medical Profession and the helpless patients had no representatives in the House of Commons, the records of cruelty, negligence, and wrong were allowed to slumber in the desks of Gwydyr Houses, where they now remain, unless they have been destroyed by the officials.

We may here observe that in the progress of the present measure through the House of Commons, no secret has been made of the intention of the Government to increase enormously the power and influence and patronage of the Poor-law Board, but such is the horror entertained and expressed by all classes of the community at the recent revelations of Poor-law mismanagement, that like the story of the frogs in the fable demanding a king, the tyranny of the Central Board is welcomed with acclamation as a relief from the King Logs and the Bumbles who have hitherto governed the friendless sick paupers. The scheme of erecting the new asylums for lunatics, small-pox cases, and fever cases, will throw great patronage and influence into the hands of the Board, which will have the power to declare the metropolis to be a single district, and will, without doubt, exercise that power, and thereby take upon itself the whole management of the new buildings. An amendment proposed by Mr. Mill (who, by the way, notwithstanding the ventilation of some crotchety notions, has shown himself well versed in Poor-law matters and favourably disposed towards the Poor-law Medical Officers) was to the effect that these Asylums should be administered by a Central Board under the local supervision of the Vestries, but it was very properly rejected, as in the event of its passing, all the old abuses would to a certainty have recurred. As it has been very truly said, the Poor-law Board, objectionable as its proceedings are in many respects, is at any rate responsible to the public and to Parliament, while the local Boards are practically responsible only to the petty shop-keeping and public-house cliques by whom they are elected, and the same system of jobbery which has lately excited so much indignation, would be perpetuated instead of being repressed, if these small coteries were allowed to control the central power.

With regard to the expenses of maintaining the lunatics, the small-pox patients, and the fever patients, who, it will be remembered are all to be collected into the contemplated new asylums, the charges will be defrayed by the whole metropolis, and not as heretofore, by the respective parishes or Unions. This is an instance of getting in, not the thin edge of the wedge, but a considerably larger portion of the instrument into the prospective machinery, for it is an important stride towards the complete classification of all the sick, disabled, and infirm poor throughout the metropolis, and the

terior intentions are not by any means concealed, but openly announced on the part of the Poor-law Board. Although for the present, it is not contemplated to erect buildings for the reception of cancerous and syphilitic cases, and a proposition to that effect, made by Lord GROSVENOR, was rejected, yet it is intimated that eventually further subdivisions and arrangements will be carried out, until probably at last the sick will be entirely separated from the able-bodied, and thus a wide scheme of classification of all sick paupers will be carried into execution, and a series of Hospitals, each containing their respective groups of patients, will be instituted. It is almost needless to remark that such a design is a most praiseworthy one, and its accomplishment would tend not only to our improvement in the condition of the sick poor, but to the advancement of medical science.

#### THE OBSTETRICAL SOCIETY OF LONDON.

THE Fellows of this Society have received a circular in reference to the determination of the Council anent their attempt to expel Mr. BROWN, which promises that the "published matters" referred to in the resolution we printed last week, will be forwarded "with the utmost possible despatch." As the matter is of the very utmost importance, not only to Fellows of the Society, but to the profession generally, we here reprint the notice:—

"53, Berners-street, March 11th, 1867.

"DEAR SIR,—We are directed by the President and Council to inform you that, in accordance with Law iv., section 2, the next meeting of the Obstetrical Society, on April 3rd, will be made special, for the purpose of considering and voting by ballot upon the following resolution of the Council, as notified to the Society at its ordinary meeting, held on the 6th inst. :—

"That, in the opinion of the Council, the published matters in relation to the performance of clitoridectomy by Mr. I. Baker Brown, justify the Council in recommending the Society to put in force against him Law iv., section 2, which provides for the expulsion of a Fellow."

"We are directed to inform you that the published matters referred to in the above resolution will be forwarded to you with the utmost possible despatch.

"The next meeting being special for the consideration of particular business, no other business will be transacted, and visitors cannot be admitted.

"We are, dear sir, yours obediently,

"G. C. P. MURRAY, M.D. } Hon. Secs."  
"HENRY GERVIS, M.D. }

We have to ask particular attention to the intimation that no visitors will be admitted. Now, although to some extent it may be argued that this matter is private, and concerns first of all the Society, we must observe that the honour and reputation of every individual member of our profession is at stake. The Council has taken the gravest proceeding against an individual, and although visitors could not expect to vote on such an occasion, their exclusion looks as if there were something to be gained by secrecy. Mr. BROWN has been publicly accused, and he should be permitted as publicly to defend himself. The whole profession has been informed of one part of the proceedings—Why not of the whole? What confidence can be expected to be placed in a ballot conducted thus secretly? What respect can be claimed for a trial thus enshrouded in mystery? What is required is an impartial investigation into the charges

which the Council of the Society lays against Mr. BROWN. This can never be effected in secret. Rather than exclude visitors altogether, we should recommend the Council, for the sake of its own reputation, to throw open the doors to all, and to engage first-class shorthand writers to take a verbatim report of the proceedings, which report should be published in their transactions in full.

We commented last week on the impropriety of the journalist expressing an opinion on a case *sub judice*. We repeat our protest. In a question of this kind all other matters ought to be eliminated from the discussion, and any attempt to bias the Fellows by public comments is to be condemned as unjust, uncalled for, and utterly at variance with the understood practice of journalism.

One other point requires notice. At the last meeting a full debate was prevented by announcing that every opportunity would be given at the forthcoming meeting for free discussion. We are, consequently, not a little astonished to hear in various directions the opinion expressed that every Fellow ought to go to the meeting prepared to vote one way or the other on the strength of his opinion about the "published matters," which, we suppose, may be in his hand to-day or to-morrow. This is to argue that the jury ought to be called upon for a verdict after the case for the prosecution is completed. Englishmen have long been accustomed to hear the defence before pronouncing, and we trust this most necessary practice will not be departed from. The Council of the London Obstetrical Society has no right to pillory an individual and assign reasons afterwards; still less has the Society at large any right to pretend to the exercise of judicial functions, and having arraigned one of their number, leave him to the tender mercies of his accusers.

#### Notes on Current Topics.

THE NEW PHARMACOPŒIA.—It is reported, with every appearance of authority, that the British Pharmacopœia, to which we have already directed attention, will not be finally published until after the meeting of the Medical Council. We sincerely trust that no unnecessary delay will take place. If the Members of the Council propose to revise the work of their Committee throughout, another summer will have passed away before the book can be in the hands of the profession. After all the delay and annoyance that has been experienced, let us have no more useless procrastination. Any two or three gentlemen would have revised the last edition in a few weeks. Here we have been in a state of uncertainty all this time, and now seem as far from the goal as ever.

METROPOLITAN POOR BILL.—Mr. Hardy's excellent measure, to which we recently drew attention, has passed the House of Commons. Its provisions have given almost universal satisfaction, so that it is not unlikely it may escape the many dangers which threaten the Government, and in due course become law. We must, however, protest against the idea that this Bill is so complete as some of our contemporaries would represent. Inasmuch as it will discriminate between the sick and the healthy pauper, and will provide for the separation of lunatics and cases of contagious diseases from other inmates, it will be a boon to the community. The establishment of dispensaries is

**THE HEALTH OF THE PRINCESS OF WALES.**—It is not at all surprising that the condition of Her Royal Highness the Princess of Wales should have given rise, especially in non-medical quarters, to a great amount of anxiety, and that the causes and nature of her prolonged indisposition should have been misapprehended, and its consequences regarded in a more unfavourable light than the circumstances strictly justify. Without pretending to possess more information on this very interesting subject than our medical contemporaries, we believe that we possess quite as much; and we believe the facts are, that about a week since very great anxiety did prevail as to the state of Her Royal Highness, although this anxiety was not shared by her medical attendants. The medical consultations were held three times a-day. Dr. Arthur Farre slept at Marlborough House every night, and we believe that the subcutaneous injection of morphia was had recourse to in order to allay the severe pain experienced by the Royal sufferer. All these circumstances, although quite consistent with the fact that no danger to life ever existed, were quite sufficient to excite the attention of the non-medical attendants of Her Royal Highness, and from some of them, no doubt, the statements which appeared in some of the daily journals were derived. We have no reason to doubt what we have all along believed—namely, that the attack has been one of acute rheumatism, a disease which, under the most favourable circumstances, requires a considerable period of time to run its course; but, on the other hand, allowance must be made for the fears and apprehensions of those who perhaps witness the sufferings which they deplore, and who, being probably unacquainted with the natural history of disease, attach more importance to the existence of pain and the continuance of sleeplessness than those symptoms deserve in a pathological sense. There is no disease, as medical men well know, so painful as acute rheumatism, whatever joint it may attack, but there are also few serious diseases in which the prognosis is so hopeful.

**METROPOLITAN TRAFFIC.**—Hardly a day passes in which there is not some serious annoyance, or some danger threatening life or limb occasioned by the overcrowded state of the main thoroughfares of London. No one familiar with the city can have failed to remark this, if he has not himself been variously endangered. The daily papers are constantly reporting accidents, as well as interruptions in the despatch of business arising solely from this cause; and, it might justly be surmised, that unless something were done the evil would necessarily go on augmenting year by year with the increase of the population. The Bill, therefore, for the regulation of metropolitan traffic, which has just passed through a select committee of the Lords, has not been introduced a moment too soon. Some striking statistics of the accidents occasioned by the present condition of locomotion in London were presented to the House by Lord Belmore in moving the second reading of that bill: "In the space of fourteen months, between January, 1865, and March, 1866, no fewer than 180 persons were killed outright, and 2175 more or less injured by carriage accidents in the streets of the capital." It is to be hoped that the bill, if it cannot entirely prevent casualties of this kind, may at all events lessen the evil, and prove a remedy to a great extent for the nuisances arising from the indiscriminate overcrowding of our public thoroughfares.

**PROVINCIAL HOSPITALS.**—The course of enquiries forced upon us by the investigations at Southampton, on which we have already commented, make it evident that many of our provincial infirmaries are in a most unsatisfactory condition. The position and privileges of the staff at such an institution are frequently ill-defined, uncertain, and likely to originate jealousies with other medical men. Our profession is sometimes called quarrelsome, but it redounds to the credit of not a few of our provincial brethren that they have been able to live in harmony with all around them under a system likely to produce such bickerings as have occurred in other places under similar circumstances.

**CHOLERA STUFF.**—The questions asked in parliament by Sir James Jervoise in reference to the weekly reports of the registrar general, seemed to imply that the honourable member must have misunderstood these reports. We gave so much consideration to the subject at the time, that it is not necessary to recur to it. In reference to the enquiry as to the intention to introduce a measure tending to obviate the loss consequent on any theory of infection, which was answered by Mr. Walpole in the negative, the registrar general in his last report remarks, "should any measure ever be introduced, it must be so extended as to obviate such losses, both of life and property as have been sustained by the people of East London. The principle of compensation applied to the accidents of railway companies may probably admit of useful extension to fatal accidents of another kind."

**THE MARYLEBONE WORKHOUSE.**—Some short time since the borough members, and some of the principal inhabitants, assembled in the Board-room for the purpose of presenting testimonials to Dr. Randal, the Medical Officer of the Workhouse, and to Mr. Fuller, the Assistant Medical Officer, in recognition of their services at the late ice accident in Regent's Park. A silver candelabrum and two silver salvers, with suitable inscriptions, were presented to the former gentleman, and a handsome gold watch to the latter. The master of the workhouse, Mr. Douglas, was also presented with a purse containing £120, and a testimonial on vellum, as a public acknowledgment of his own and his wife's carefulness, kindness, and promptitude, at the time of that lamentable occurrence. The guardians have also made an addition of £50 per annum, to the joint salaries of Mr. and Mrs. Douglas, in consequence of these services, as well as of their generally intelligent and humane treatment of all classes of poor in this district.

**THE SANITARY CONDITION OF THE EAST OF LONDON.**—The Medical Officer of Health for the District of Whitechapel, Mr. John Liddle, has just presented his annual report on the sanitary condition of that district for the year 1866, and from the circumstance that the visitation of cholera was more severely felt in this portion of the metropolis last year than in any other locality, the brief document will command a great amount of public attention. It tells us that the deaths for the year are greatly in excess of any year since 1848; that in 1849, when a severe epidemic of cholera prevailed in London, the total deaths in the Whitechapel district were 2778 in a population of 71,879, and that in 1866, in an estimated population of about 78,000, the number of deaths was 3492. In 1866 the death-rate of the district was 4.45 per cent., while in 1849 it was only 3.86 per cent. In both of these years the deaths

undoubtedly a step in the right direction, since nothing can be more improper than for the medical adviser to supply the drugs he may consider appropriate at his own expense. Giving the Poor-law Board "extra eyes" on the doings of the local authorities is the natural result of the recent revelations, so that the public have eagerly caught at the proposal to place nominees of the Poor-law Board upon the local Boards. Again, the transfer of certain charges to the common fund could not but be supported by those who have been agitating for an equalisation of the poor-rates. The measure is, therefore, possessed, amongst other excellencies, with the very important one of being so skillfully contrived as to be likely to win to itself a large number of supporters from various sections of the community. This is of considerable importance as to its probability of passing. In many points it is but the insertion of the thin end of the wedge, and should it become law we shall soon see its expansive nature. We sincerely hope that it may be indeed the commencement of a better era. It is because a larger measure might have failed that we welcome this. Founded, as it essentially is, on the system that has worked tolerably well in Ireland, we look forward to the time when the Poor-law of the whole United Kingdom shall be placed on a satisfactory basis. Nevertheless, we cannot conceal from ourselves that the medical element, neither in Ireland nor in the proposed metropolitan system, has assigned to it the preponderance to which it may justly lay claim. Dr. Vanderbyl, Member for Bridgewater, made some useful suggestions in his place in Parliament. Were doctors only as numerous as lawyers are in the House, we should not in this 1867 be dealing with the question. To the profession is to be attributed the fact that the public is determined to deal with the subject at all. Let us be as true to ourselves as we have been to the poor, and we shall force the Government to deal differently with us. It is not the wish of the public to treat the profession badly, and unless justice be done we must no longer plead our cause before legislators, but carry it, as we have done that of the suffering poor, to the supreme tribunal of public opinion.

**AMENDMENT OF THE MEDICAL ACT.**—It is stated that the present Home Secretary is disposed to assist the Medical Council in passing an amendment to their "Act." We doubt, however, whether that body is likely to propose anything that will give general satisfaction to the profession. Strangely enough we adopt a system of protection, but refuse to appoint efficient instruments to carry out that policy. Either the public want protection or they do not; but under the "Act," which was proclaimed in 1858 to be thoroughly efficient, quackery is as rampant as ever. The cumbersome machinery carried out by the nominees of the "vested interests" has given us a "Register" and a Pharmacopœia, the necessary revision of which is not yet complete. The mountain still labours. We await the result.

**THE DIRECTOR-GENERAL OF THE MEDICAL DEPARTMENT.**—Dr. Logan is to succeed to this important office. We have refrained from entering into any discussion respecting his merits compared with those of the eminent gentleman whose name has been put forward by some as a sort of competitor. It was not denied by any one that either would make an efficient public servant, and we can scarcely consider it the province of the medical journalist to attempt in such a case to sway the opinion of those who

have the appointment, by raising a prejudice against an individual worthy of all honour, or by seeking to promote the interests of a personal friend. Where some principle dear to the profession is at stake, we shall never hesitate to enforce our views by all the arguments at our command, but we feel convinced that perpetual meddling in matters of little moment, and in which we have virtually no control, is not calculated to increase our influence with those whose support is most worth having. Dr. Logan brings to his office large experience and great popularity. The position to which he succeeds is one of great responsibility. It will be a proud boast for him should he be able to wrench from reluctant authorities that justice for his subordinates which is due to the medical profession. We trust he will remember what will be expected of him, and achieve for the medical department those concessions which it has so long demanded. Here is an opportunity for distinction that more highly-placed officials might envy.

**LOCAL ANÆSTHESIA IN VETERINARY PRACTICE.**—On Tuesday the 12th inst., Dr. Richardson demonstrated his method of producing local anæsthesia before the Royal Society, for the prevention of cruelty to animals, and very ably pointed out the practicability of his process in veterinary surgery. There were present at the meeting—the Earl of Harrowby, in the chair; Mr. John J. Briscoe, M.P., Mr. W. Mackinnon, M.P., Mr. S. Gurney, M.P., General Sir John Scott Lillie, Dr. Fraser, Dr. Sedgwick, Professor Tuson, and a large attendance of members. It was stated a single pound of ether worth 4s. 6d. would suffice for twenty operations. Clearly, therefore, expense is not likely to prove an obstacle to its general employment, and there is no difficulty whatever in producing the insensibility. By Dr. Richardson's simple method an uneducated person affords the assistance the operator needs. The society will print Dr. Richardson's paper for general circulation, and they can scarcely expend their funds in a more practical way.

**SPECIAL WARDS OR SPECIAL HOSPITALS.**—In the campaign that has been carried on so energetically against special hospitals little has been said of their origin except in the most offensive manner. We have been making an investigation into some of these institutions, and shall recur to the subject shortly. We must, however, notice that it has recently transpired that St. Bartholomew's is about to create special departments. More than this, the gentlemen appointed to them are not to be members of the present staff. This liberal step we hope to see universally imitated. It is undeniable that not a few special hospitals owe their existence to the absence of efficient departments. Where these have been organized, in some instances they have been confided to the care of men already having a place at the institution. Much discontent is thus naturally produced. Able and conscientious men are excluded from appointments in the general hospitals, and are driven to the smaller institutions which they would gladly relinquish, did not they feel that the illiberal system frequently pursued prevents them from becoming attached to the hospitals they most desire. This monopoly produces incalculable evils wherever it exists, while, where the liberal system has been tried and the staff enlarged, the greatest benefit has accrued. We commend this fact to the hospital authorities where changes are contemplated, and urge upon them the liberal course as the most beneficial to the charities over which they preside.

in the London Hospital are included. These very striking statistics are well calculated to attract the notice not only of the local authorities, but of the conservators of the public health throughout the metropolitan districts, and it is to be regretted that the force of the cholera epidemic should have fallen with such deadly severity upon a district so densely peopled, but at the same time so poor (owing to the great preponderance of the indigent classes), and therefore so little able to meet any extraordinary expenditure in the way of sanitary supervision and medical attendance. The facts thus disclosed almost seem to warrant a general instead of a local taxation, when wealthy and salubrious districts escape the visitation which falls almost exclusively on the poor ones. The London Hospital, as being situated in the Whitechapel district, is noticed in the report as returning a large number of deaths from pyæmia, and the Medical Officer of Health considers the frequency of this disease in the hospital to be a matter calling for the serious attention, not only of the medical staff, but also of the governing body of the institution. He thinks that in order to improve the sanitary condition of the hospital, and to obviate, if possible, the recurrence of endemic disease, a report should be prepared by the whole of the medical staff, pointing out any sanitary defects, if they can be found to exist, and the means of providing for their removal. We should state, however, that the London Hospital is by no means singular in presenting a number of cases of pyæmia, erysipelas, diffuse cellulitis, and other diseases bred within the walls, or at least propagated from patient to patient, and probably most, if not all, the great hospitals in London are liable to the same observation. The last volume of St. Bartholomew's Hospital Reports distinctly announces that such a state of things exists in that establishment, and the circumstance is specially referred to by the editors of the volume.

**THE LATE OUTBREAK OF CHOLERA AT NEEMUCH.**—The literature of cholera treatment is enriched by an admirable report on the epidemic as it affected the 45th Foot, from the pen of Assistant-Surgeon T. W. Martin. This report will be found in the last volume of the Statistical, Sanitary, and Medical Report of the Army Medical Department. Dr. Martin's report is succinct and complete in every particular, giving in a lucid form every information on the point bearing either on the causes, progress, or result of the epidemic. This report is worthy of the very high terms in which it has been spoken of by Professor Maclean of Netley, and may serve as a model for similar valuable contributions. The details of the report are such as to be unsuited for transference to our columns, but are well worthy of noting by cholera students.

## Legal Intelligence.

### WESTERN CIRCUIT.

EXETER, MARCH 12.

CROWN COURT.—(Before Mr. Justice BYLES.)

George Lee was indicted, for that he, being an attendant in the Devon Lunatic Asylum, did assault and ill-treat Frederick Lockyer, being a patient in the asylum, on the 9th of January. There were other counts varying the charge.

Mr. Lopes conducted the case for the prosecution; and Mr. Collins defended the prisoner.

In this case, from its peculiarity and importance, we detail the evidence.

We may state that before the lunatics were sworn the Judge asked them if they were aware of the nature of an oath, and

they fully answered the question, and then gave their evidence much better than most sane witnesses.

G. J. Saunders—I am the medical superintendent of the county asylum. Frederick Lockyer came there in March, 1861; he has been there four times for mania. On the 9th of January I went to No. 3 ward and found Lockyer in bed. I gave orders for him to be stripped. I examined his breast and found a bruise six inches in circumference and three ribs broken; there was a severe injury to the left eye, caused by some weapon entering the eye; there was great pain, and he could not bear the light. It might have been inflicted by the shutter pole. The prisoner was on duty that morning in that ward.

Cross-examined—A shutter pole or the brush might have caused the injury. I have charge of the lunatics. Lockyer was a noisy, troublesome patient, not violent. He had been for twelve months in the refractory ward. Stoneman was assistant-attendant under the prisoner. About fifty patients slept in that ward. Lockyer's delusion was that he was workman to the devil; he lost it within a few days; he had periods of excitement without delusions. He was capable of giving an account of what took place before his eyes. He has given rational accounts of things.

Frederick Lockyer, by the JUDGE—I am 54. I know the nature of an oath.

By Mr. Lopes.—I am in the lunatic asylum. Early in January I was in my bedroom. The prisoner was head keeper. Stoneman came in. After that the prisoner came. I told my pitiful tale to him, thinking he would lean on my side. He said, "You have wetted your bed, have you?" He said he should take none of my abuse, and he took the brush and he pushed it in my eye, and he then struck me right and left on the head with his fist. I stood up to him and said, "Come on my son;" and I gave him a couple. Stoneman came up with a pole, and I thought I had better drop this game, seeing two of them. The prisoner struck me several blows. I called "Murder," and some people came, and then the game was stopped. My ribs were broken, and I am blind in one eye from the usage.

Cross-examined—I have kept account of the day, being the 9th of January. I told the magistrates so. Stoneman came in first that morning. I said, "Tom, you are in a bad temper." "Yes, I am," he said, "and that you'll soon find;" and I thought it was time to be off, and I ran out. He struck me about a dozen times with a pole; he rammed it into me and broke my ribs. I did not strike him. He drove me into the day-room. I was not a bit excited. I was mild as milk. I can let my temper rise and fall. I went for my clothes, and after that it was I gave Lee two blows. The blood flowed about a bit. I think I gave him two good ones. I did not tell Stoneman I would not get out of bed.

Re-examined—I did not strike Lee till he struck me. Stoneman had tanned me well before.

George Chaplin—I know the nature of an oath. I am in the lunatic asylum, speaking conventionally, when I am not here or elsewhere. I was in my bedroom at six that morning. My room adjoins Lockyer's. Stoneman came up and entered Lockyer's room with the pole in his hand. I heard Lee say to Stoneman, "What! has he wetted the bed again?" and Lockyer spoke in an insulting manner, and he gave him a gentle push with the brush. Lockyer caught hold of the foot of the brush and there was a violent struggle; in pulling it the stubble came into the eye of Lockyer. Lee regained possession of the brush, which he threw down, when Lockyer attempted to strike him. Lee then struck several blows on Lockyer's abdomen, who then cried, "Oh, my Saviour, save me!" I have a great abhorrence of anything filthy, and said, "That serves you right, Lockyer."

Cross-examined—If being jovial and full of mirth and has his whim, he is well enough, but when he is wrathed he is a devil untied. He became violent. I did not observe any blood on Lee's face at the time. It appeared to me in an hour after that Lee sympathized with Lockyer and was sorry for what he had done.

John Bowden—I am head attendant at the asylum. I was there at six that morning. I saw the blood on Lockyer's face and eye. I went to Lee, who told me that Lockyer had fallen foul of him and struck him three times. I made a report to Mr. Richardson.

Cross-examined—Lockyer was much excited at times; he had been placed in the refractory ward. He was troublesome, but not dangerous.

J. P. Richards—I am assistant medical officer. I examined his eye, which was much swollen from a recent blow.

Mr Collins addressed the jury for the prisoner. He had borne an excellent character. Did the prisoner or Stoneman commit these injuries? The witnesses to-day were sane, to-morrow they might be raving lunatics. What might they not have been on the 9th of January? All said that Lockyer was a quarrelsome, troublesome patient. These unfortunate men could assume almost anything. If he had touched upon Lockyer's delusion what a scene there might have been in court. If they were so completely sane, would they be kept in the asylum? Could they doubt that these unhappy men had talked over this matter? Could they doubt that it was Stoneman, and not the prisoner, who had caused the injury? Could they place dependence upon what these men said, when to-morrow they might give a totally different version of the affair? In a lunatic asylum the keepers were bound to keep the patients under proper restraint, and Lee was only doing his duty.

The learned Judge summed up. The prosecution was a most proper one. They would take care and protect these unfortunate persons from violence by their keepers, but they would not convict those having charge of them unless the evidence justified it.

The jury returned a verdict of not guilty.

John Stoneman was indicted for that he, being an attendant in the Devon Lunatic Asylum, did beat and ill-treat Frederick Lockyer on the 9th of January. Other counts varied the charge.

The prisoner said he had retained Mr. Carter to defend him immediately after the occurrence, and he hoped his lordship would postpone the trial until Mr. Carter came into court.

The Judge said he was sorry for it, but he could not help it, as he had no other case to go on with. (Mr. Carter was engaged at the Guildhall before Mr. Pridcaux, Q.C., who was trying city prisoners there, and had sent up his brief to Mr. Folkard.)

Mr. Lopes appeared for the prosecution, and Mr. Folkard defended the prisoner.

The evidence was the same as was given in the last case.

Frederick Lockyer swore that the prisoner had rammed the pole into his ribs.

In his cross-examination he said he thought that the prisoner was not quite right; he thought it would be a good thing for them to change places. He thought the patients had more sense than the keepers. He had been a coachman, and had a very good character, and hoped to get another situation. He was in the refectory ward by choice, because he liked the people there. He was a good tempered fellow, unless he was put upon.

Mr. Folkard addressed the jury for the prisoner. The only evidence against the prisoner was an admitted confirmed lunatic, without the slightest corroboration. The story altogether was a most improbable one.

The jury acquitted the prisoner.

The Judge told the prisoner to be careful for the future.

## Correspondence.

### ON NATURAL AND ARTIFICIAL ELECTRICITIES AS THERAPEUTIC AGENTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—In my first letter of February 22, I premised that there are two kinds of electricity—the natural and artificial. I will proceed, with your permission, to consider the first of these two, and to show how that electricity is generated in the human body by fixed and immutable laws.

It is now a fact, recognized upon scientific data, that no decomposition takes place in the physical world (whatsoever may be the element) without the action of that species of electricity which exists, first, in the bowels of the earth, and therein decomposes the various elements which are destined to the formation and nutrition of every kind of plant. Without this we should have no vegetable kingdom, and, consequently, no animal life. This first and indispensable principle is the very starting point of all that exists.

That electricity is produced by chemical decomposition, and this decomposition is the great universal phenomenon, without which the world would remain uninhabitable, an inert and unchangeable chaos.

To this form of electricity I have given the name of "chemic," as being the result of chemical decomposition, as perpetually acting upon all chemical compounds and vivifying all that is animate on our globe. The above incontrovertible fact is the key which unlocks the door of all the physical arcanæ of nature. Starting, then, from this fact, I make the following deduction:—

If fermentation or decomposition evolve electricity, is it not philosophically correct to ask, whether the living body is not itself a decomposing machine?

If so, as a matter of course, that kind of electricity is generated in the body for a wise and useful purpose, as all and everything else is which emanates from the hands of God. This electricity possesses a double character and action of cause and effect, and effect and cause. That is to say, decomposition produces electricity, sometimes, indeed, in so small a quantity as to require a delicate electro-meter to ascertain its presence; but when in sufficiently large quantities, then the electricity, thus generated, in turn becomes itself a decomposing agent. As I insist upon this fact, perhaps a simple illustration will suffice to explain more clearly my meaning. What are the articles of food destined for the nutrition of our organism? Nothing but inert substances, which, in course of time, are converted into blood, but by what process? By fermentation and decomposition. Accordingly, when the food is transformed into chyme in the stomach, there is a production of electricity in proportion to the quantity and quality of the substance received in that organ. This is the first step. Next, when the chyme is transformed into chyle in the duodenum, there is another production of electricity. Electricity is produced, according to the same law, all along the small intestines, and the larger one, the colon. Then, when the blood is formed and perfected, it is decomposed into all the various organs, into all the secretions, either mucous or serous, and so forth, until ultimately the body itself is decomposed for the expulsion of the refuse of its wear and tear, and its old materials, in order to admit new ones, to be subjected in their turn to the same processes again. So it is that electricity is being constantly generated in the body by a law which involves its very permanence and duration.

We are justified, then, in coming to another consideration of paramount importance, which is that, if in the state of health we generate the precise quantity of electricity duly required for the performance of all the vital functions, what must happen when that electricity falls short? Well, electricity is to the body like steam to the engine. If there is not sufficient for the full working of the machinery it slackens, and if new steam is not reproduced the machinery ceases working altogether. This is an illustration of the action of electricity on the living machine. If there is not an adequate supply of electricity the living engine loses power—the circulation becomes languid, nutrition is deficient, and the secretions imperfect. If this deficiency is not supplied in time, the want of it becomes the fruitful cause of various indispositions and diseases, more or less grave and fatal. Then it is that we require electricity to re-establish the order and functions of the debilitated organism; but shall we obtain it if the stomach, which we may compare to the boiler of the engine, is itself out of repair—if it can no longer receive the quantity of fuel requisite for the generation of electricity? and if all the organs depending on, or subservient to, its healthy action do not receive from it the impulse necessary for that portion of electricity essential to the due discharge of their functions! What is to be done in this case? We must have recourse to artificial electricity; we must continue to saturate the whole body with ready-made electricity, which is produced by the same method as that generated within the body itself. This electricity I denominate *chemic*, and it possesses the same virtues, properties, and qualifications as the natural. I immerse the patient, then, in a bath so contrived as to introduce the electric fluid at once into the whole organism, and to make it permeate every atom of which the body is composed. I call this an electro-chemical bath, because the electricity which it supplies promotes these chemical functions, upon the right discharge of which health depends, and the restoration of it where it has been impaired.

Various other names may be given to this species of electricity. I have adopted the generic one, but it might be termed with equal propriety "The Electricity of Decomposition." Facts will bear me out in this appellation. When I was a student I was taught that there were but thirty-two simple bodies, which, as they could not be decomposed by any chemical process, were considered as primordial elements. Since that period, however, they have been decomposed, and

we have now double the number. By what means has this been effected? By electricity.

Thus it is that this kind of electricity is the greatest decomposing power in nature. As such it has also another therapeutic virtue. When the body is impregnated with it, it decomposes all the extraneous substances which are retained either in the bloods or in the tissues, and these, when reduced to their atomic condition, are carried out by the electricity through the pores of the skin. The organism is thus relieved of every kind of substance or matter which is heterogeneous to the constitution.

With equal propriety we might term it physiological electricity, as promoting all the physiological functions; or, again, "medical electricity," as that employed for the cure of diseases.

I propose, in my next paper, to treat of that other natural electricity called "static," but which I prefer to denominate "atmospheric." It is that electricity which we breathe, which floats in the atmosphere, and is found upon the surface in opposition to that which exists below and within the earth.—I remain, dear sir, yours truly,

J. CAPLIN, M.D., F.A.S.L.

### THE ROYAL SOUTH HANTS INFIRMARY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—This question has been so thoroughly discussed in your paper, and treated with so much impartiality, that I am unwilling to throw into the balance the feelings of the partisan.

The controversy commenced in your columns in 1854, and has been maintained principally by your aid to the present time. I am therefore desirous that the review should emanate from some disinterested member of your staff.

The interest of the question is not confined to Southampton. Its results seriously concern every medical man who practises within a given distance of a borough or county hospital. The thanks I have received from practitioners—north, south, east, and west—demonstrate that my past efforts have been appreciated, and is at least an encouragement to persist in the same course until my object shall have been attained.

The personalities which have been introduced into the discussion are abominable and greatly to be deprecated. An impartial investigator will discover that during the whole of the controversy, from 1854 to the present time, my opponents have unceasingly made them the substitute for argument. Take as a specimen the calumnious charges, and their complete refutation, in the printed letter enclosed, dated Feb. 6th, 1867, which, independently of what had previously occurred, at once roused me to do all in my power to support the efforts of Mr. Scrase, who is a retired member of our profession, therefore personally disinterested, and whose object in taking up the question was, I believe, purely philanthropic. I had never exchanged a word with Mr. Scrase on the subject until he was in the heat of the contest.

The spirit of your article of 6th March will, I feel convinced, meet with general approval; but unfortunately mistakes as to facts have crept in, which I am sure you will be only too anxious to correct, since other journals have seized on the same points and magnified them to the utmost. The journals referred to having written very diversely and strongly within a comparatively short time will be called upon to explain. We take it for granted that, like the rest of their recent writings, the explanation will neither amuse nor interest, but simply endorse the opinion generally entertained of sudden changelings.

The mistakes referred to are, that none of the cases brought forward by Mr. Scrase in support of his allegation of bad surgery are recent.

The assertions of the inquirers, as reported in the papers, and it must have been most difficult to report correctly, for the sound which emanated from the room in which the inquiry was conducted resembled more the ravings of maniacs than the converse of calm dispassionate inquirers, would lead most people to the same conclusion.

Now one of the cases extended so far back as eight years, all the others were as recent as they could have been to have given the infirmary surgeons the full advantage of their treatment. If too recent, their reply would have been that the tumour would return again, as it had done thrice before—that the fractured thigh had not recovered its full powers, &c., which the poor fellow had been told only a few months ago—that the eye might yet improve, &c., &c., &c.

Another mistake, and one of considerable importance is, that several years ago an inquiry was made into some alleged

mismanagement of that institution, and that the very cases recently brought up were then alluded to. This statement did not appear in the newspaper reports, and is quite a mistake; consequently the source of such a mis-statement should be sifted. The former inquiry, conducted in even a worse spirit, if possible, than the recent one, took place in 1854. The date of all the cases investigated, or rather of all submitted for investigation, on Monday, February 18th, 1867, preclude the possibility of the previous inquiry including them; whilst the names of a large number of complainants can be given as having since appeared from time to time in the medical papers—Gregory, Slade, Jockyeau, Channell, Hadden, Thorne, &c. The right management of the institution would at once alleviate personalities. Let merit in the appointments be in any way recognized, the three years' breathing of the Southampton atmosphere rendered unnecessary, the plurality of votes abolished, &c., &c., then will the now so-called charity be made a really useful institution, and prove what it ought to be, a blessing to the poor, a medium of uniting the medical men of the town and neighbourhood in good-fellowship, besides being of real service to the general community, instead of continuing to prove, as it has done for a quarter of a century, an apple of discord and everything else than what it was designed to be by its benevolent founders. The misunderstanding consequent on the violence and confusion at the recent inquiry is fairly rectified in the comments thereon which appeared in the *Southampton Advocate*, and which I herewith enclose.—I am, &c.

EDWIN HEARNE.

### DISPENSARY ABUSE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—If it be true that "to every thing there is an allotted use," I conceive the converse is equally correct—viz., to every thing there may be an abuse, and of the many abuses to which the profession of medicine is subjected, it may be conceded the abuse of the *red ticket system* is one of the most reprehensible. Why it is that Dispensary Guardians in general are different from other men in their appreciation of the wants and services of others, is a question on the discussion of which it is not my intention now to enter, but the fact remains uncontroverted that so they are, and use their power to an extent quite beyond the scope and intention of the poor-law authorities, for I venture to assert it never was the desire of the Board that the medical officer of a dispensary should attend gratuitously, either by day or night, patients in much better circumstances than himself, although they might have the privilege of being a relative or friend of an all-powerful guardian, and therefore able at any time to procure a red ticket.

In illustration of what I have above asserted, I would desire to record the following instances which came under my observation a few days since, and form the ground-work of the subject, which, with your permission, I wish to bring before the notice of the profession through the instrumentality of your pages:—

A few days since, happening to call on a brother medical man in charge of a dispensary in my neighbourhood, casually looking over the "Relief Register," I observed the following entries of that morning:—1st. "This man occupies a house valued at £8 a-year, is a skilled carpenter, has a good piano-forte, &c., &c., in sitting-room." 2ndly. "This child's father is the owner of four cabs, two cars, and eight horses;" and "a butcher's child, earning £1 6s. a-week." At the same time my friend assured me these were only a few of the very many instances of a similar nature daily occurring, and that this evil was on the increase, he having no power to refuse such calls, the only redress being to bring the matter forward at the monthly meeting of the committee, when the subject being considered, "past and gone," was consigned to oblivion, only to be repeated on a future occasion.

Now, sir, I think you will agree with me that "these things should not so be," and as a remedy I would suggest that every medical officer attached to a dispensary on his induction to the duties thereof, should be supplied with a correct list of the names and places of residence of all persons within his district entitled to gratuitous aid from the dispensary medical officer; such list to be made out by the relieving officer, and approved of by the dispensary committee at its general meeting every year, or oftener if requisite. I am fully aware the above plan would be attended with considerable trouble, and require frequent supervision and correction, yet I think the very same objections hold good with regard to the register of qualified parliamentary voters, and of those liable to poor's rate taxes, &c.,

&c. By this means also the medical officer would be enabled, as most clergymen are, to recognise and personally know "the flock over which he may be placed." If these means were adopted, and the number of those entitled to gratuitous dispensary relief ascertained, should any properly entitled thereto be excluded, it might be provided that such should make application to the committee, and if approved of, then placed on the list supplied to the medical officer, thus preventing any one guardian having the disposal of gratuitous relief to any one he pleased. Should you, sir, consider the above worthy insertion, with a view to ascertain the mind of the profession thereon, and should same appear to them to meet the requirements of the case, I shall on a future occasion, with your permission, have much pleasure in adverting to the subject with regard to the "qualification" necessary to entitle parties to be entered on the dispensary officer's list, &c., being deterred on the present occasion from so doing, until the above subject of dispensary "reform" shall have been brought before the profession at large through your medium.—I remain, faithfully yours,  
JOHN S. A. CUNNINGHAM, M.D.

### THE ACTION OF HENBANE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am in a dilemma, and will feel thankful for a little light. Nearly a quarter of a century since, I held the office of Resident Medical Officer to a great hospital for the space of ten years, where, from repeated observation, the conviction was forced upon me that hyosciamus possessed no narcotic or sedative property whatever. I have ever since expressed and acted, when opportunity offered, on that opinion thus deliberately formed. Other practitioners of high standing have pooch-pooched this opinion, and overruled it by simply throwing the weight of their great experience in my face, this I had to school myself to bear with patience. But a time at last came when I rejoiced to read in the MEDICAL CIRCULAR (some four or five years since) a report by a certain commission appointed in Paris, expressly to test the properties of all varieties of this drug; the roots, the stems, the leaves, the flowers, the capsules, and the seeds were severally and conjointly experimented on in every possible form of tincture, powder, extract, infusion, decoction, &c. The result of all their experiments, so far as I remember, was, that they pronounced hyosciamus to be destitute of all narcotic or sedative properties, that it produced nausea, vomiting, purging, poisoning—anything but quiet and repose.

Sometime after the report of this Commission, I revisited the great hospital where I had lived, after an absence of almost a quarter of a century, and there saw one of its celebrated surgeons pass a catheter, a rigour ensued, and he directed the conventional dram of tincture of hyosciamus to be given at once, just as in the olden time. I requested him to inform me if I had been dreaming all these long years. And now again, in your journal of March 8th instant, I read amongst the questions for examination in the King and Queen's College of Physicians in Ireland the following:—

"Prescribe a draught containing tincture of hyosciamus for want of sleep in a case of typhus occurring in the adult, &c." Now I want to know from you, should not this be instead, "Do not prescribe a draught containing tincture of hyosciamus for want of sleep in a case of typhus fever, &c."

My object is simply to express what I believe to be a well ascertained but much neglected truth, regardless of the store of idols of Bacon, taken from the rusty armory of their experiences, by which I may be assailed by the mass of the profession who stand in the forum or market-place, to any of whom you are at liberty to give my name if required. I enclose my card, and have the honour to remain, sir, your obedient servant,  
J. C.

### QUACK ADVERTISING.

"Household Almanack" Office,  
18, Lower Ormond-quay, Dublin, March 11, 1867.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has just been called to an article in your last issue headed "Quackery Triumphant," in which the writer (Dr. Cunningham) refers to the "Dublin Household Almanack," of which I am the proprietor, in terms so totally devoid of accuracy or truth that I am quite at a loss to know why he has condescended to adopt such a discreditable mode of illustrating his subject.

Dr. Cunningham states that the "Dublin Household Almanack for 1867" contains only 24 pp., and that, of that number, the advertisements occupied 12 pp., six of these being crammed with quack advertisements.

The best answer I can give to this gross mis-statement is to send you a copy of the Almanack in question, which you will perceive contains no less than 72 pp., being three times the number stated by your correspondent; of which the advertisements occupy as much as 23 pp. If Dr. Cunningham's statement be true, his copy must be an imperfect one.

He further states that there are 6 pp. of quack advertisements, amongst which he includes "Blair's and Frampton's pills, Hayman's balsam of horehound, Dr. A. Coffin's trichoporous, Norton's pills, Keating's coughlozenges," and many others, which are sold by the most eminent chemists in this city. I have nothing to do with the question of what are "quack medicines" and what are not so, nor do I think it a publisher's business to decide this question. It is one emphatically for the medical profession, assisted by public opinion, to deal with by means of corrective legislation; nor will a remedy ever, in my opinion, be found for the alleged evil by abusing newspaper proprietors and others who insert these advertisements, although I think much could be done meanwhile by the establishment of private hospitals or dispensaries for the respectable classes, somewhat on the principle of the "Maison-de-Sante," to which persons who have the means to pay for regular professional assistance could resort for that purpose. In this way you would soon find that the genuine coin would be preferred to the baser metal, and those who are duped by unprincipled and unskilled pretenders would gladly prefer the legitimate practitioner, and thus be saved from wholesale plunder and the consequences of an imperfect cure. The exhibition of such dispensaries should, however, be made known by judicious advertising, otherwise they cannot have the desired result of spoiling the trade of charlatans; and I may add in conclusion that to insure entire success a degree of privacy (which is the stronghold of quackery) must be guaranteed, or the classes in question will persist in visiting those places where they are sure it will be observed.—Your obedient servant,

THOMAS HACKETT.

[The copy of the Almanack forwarded to us bears out the statement of the proprietor as regards the unimportant question of dimensions. Dr. Cunningham is perfectly justified in stigmatising the advertisements which occupy a large proportion of its space as disgusting and injurious to public health and morals. We differ from Mr. Hackett in the opinion that it is not the business of a publisher to decide what are quack medicines. It is certainly the duty of a respectable publisher to form an opinion, so far as he is able, and if obscenity or dishonesty are patent in the advertisement, to expunge it. The offence is greatly aggravated in this case, because the publisher is also the vendor of these nostrums, and may be reasonably expected to possess information as to the character of their promulgators which newspaper proprietors seldom have.—ED. M. P. & C.]

### OBSCENE QUACK ADVERTISEMENTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the number of your journal for March 6th, a letter appears from Dr. Cunningham which relates to a subject (*viz.*, that of indecent quack advertising), which, it must be admitted, deserves serious consideration from all who feel interested in the welfare and dignity of our profession.

In that communication he implicitly alludes to a part of the subject which in my mind is that of most seriousness amongst the questions involved, and which it is therefore my object in writing this letter more explicitly to call attention to. I refer to the fact of newspapers of respectability giving insertion to the offensive documents under consideration.

That men lost to a sense of the dignity and respectability of our profession should hang about its outshirts, and scandalize it and themselves by the indecent system complained of, is no more than we could expect. These filthy members of society prey upon the interests of every profession alike, and every community must be prepared to compound for a certain proportion of "black sheep" amongst its members, and perhaps the medical profession suffers more in this way than do the others; that, moreover, these individuals should adopt any means, however unworthy, of thrusting themselves into public

notice is not matter of surprize, and is an evil which we can, I think, scarcely expect to check altogether, without interfering too seriously with that boasted "liberty of the subject," which must always leave it in the power of certain persons to make blackguards of themselves without transgressing the letter of the law. But, sir, I do think that our profession has a right to expect better at the hands of the respectable portion of the literary community, than that it should in any respect be found to value itself with these enemies of its best interests. Surely the editors of respectable daily journals like the *Irish Times* do not require to be told that notices such as those quoted in Dr. Cunningham's letter are injurious to our profession, are distasteful to its reputable members, and in their publication are doing a damage to society, and that therefore the paper which publishes them is thus abusing that power which it is the constant boast of "the press" that it wields for the public good; and if they do require to be told so, let them now, sir, learn the lesson from you, and we have every right to expect that it will be attended to.

Nothing tends so to perpetuate imposture as its finding its way into respectable society, and I think it must be pretty evident to any one that the vitality of the medical quackery system is kept up by no single circumstance so much as by the place its advertisements have secured in the columns of respectable journals. So long as its exposition is confined to such means as an obscene placard in a dark corner, or a card thrust furtively and confidentially into your hand by some skulking wretch, it wears on its very surface the stamp of surreptitious and dishonest humbug, which almost every one can easily discriminate, and there is comparatively little danger; but when it takes the form of a prelude to the day's news, and that in a paper which will find its way into all respectable circles of society, the credentials of the system are not so easily detectable, and real and serious danger and damage are liable to result. Besides all this, the appearance, in such a place, of such a document cannot be felt as other than an insult to the respectable portion of our profession. Now surely all this is not intended; and it is to be hoped that the sin is simply one of thoughtlessness. I cannot think that the conductors of the public journals, in which this practice of giving insertion to indecent and quack advertisements maintains, perceive that they are lending themselves to all this in so doing. They do not mean, I am confident, to foster the growth and spread of dishonesty and imposition; they do not mean, I am equally confident, to offer any insult to the respectable members of the Medical profession; and yet that they are daily doing both, is simply a fact. I do not forego the hope that it is only necessary to have this pointed out to them to have the remedy promptly and effectively adopted. I am, sir, your obedient servant, an

M. B.

### NON-STIMULATING TREATMENT OF DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—In your issue of the 6th instant you devote a leading article to consideration of the above subject in its relation to medical practice in our Poor-law Unions, and you express regret that I should have made an "unconsidered proposal to save money by refusing stimulants for the treatment of disease" to the Guardians of the North Dublin Union. That you should have arrived at this conclusion surprises me not a little, for you have yourself done me the favour on several occasions of laying my letters on this subject before your readers, and I have not until now had any reason to believe that my statements to the public on the subject—which not only found an extensive circulation in your journal, but also in the columns of some of our daily papers—were not alone interesting from the facts stated in them, but also likely to be useful in a medical point of view, by drawing the attention of our physicians generally to the mode of treatment adopted by Dr. Nicolls, and which has been practised by him for eighteen years with the most satisfactory results, and which you yourself characterised as "most encouraging" in your issue of 25th October, 1865. Nearly two years' further experience have confirmed the value of Dr. Nicolls' non-stimulating practice.

I wish you could have made room for the entire statement I laid before our North Dublin Union Board on the 10th December, as the extracts you have given from it omit several of the important facts which justified me in again drawing public attention to the subject. You do Dr. Nicolls and me great injustice in supposing that saving money is our chief object, and I do not think either of us have written a line which justifies you in coming to that conclusion.

I have shown, on the testimony, not of Dr. Nicolls alone, but also on that of several other medical men, that the use of alcohol in the treatment of disease, as it is still used by many physicians, and as it was more generally used only a few years ago, is a practice opposed to the latest discoveries of science as to the medicinal value of this poison. It is not proposed by any that its use should be altogether given up, for it is believed there are cases in which no other known medicine can be used with equal chances of success; but if I have shown, on able medical testimony, which I think cannot be disputed, that such cases are few indeed, surely I am fully justified in informing all our Boards of Guardians that sickness is rendered more inveterate, that mortality is increased by the free use of alcohol as a medicine, and that the poor in our workhouses, as well as the ratepayers, are injured by the practice. The comfort and recovery of the sick poor should, no doubt, be the first object of all poor-law guardians, and we have no reason to doubt that it is not; but we have another duty also to perform, which is, not to tax the ratepayers beyond what is necessary for securing those objects; to tax them heavily for the purchase of articles which do mischief instead of good, which destroy life instead of saving it, and which keep alive a sad delusion in the minds of men that alcohol can be used with safety, even by persons in health, is contrary to the dictates of common sense, and the sooner such delusion can be got rid of, the better it will be in every sense for all parties.

Dr. Edmunds, of London (the last authority I have seen on the subject), lately delivered a lecture in Manchester, on "alcohol as a medicine," in which he points out in a most masterly manner, that alcohol is not a stimulant in any true sense of the term, but that it always acts as a narcotic. His address must arrest the attention of medical men, and hasten the time, which I believe is not far distant, when physicians will place alcohol in the same category as they have placed mercury and blood-letting; use it sparingly in practice in future, and teach men that it is indeed the enemy of the human race. If Dr. Edward's published opinions, which he supports by apparently unanswerable anatomical and physiological reasoning, be not proved to be unsound, the present use of alcohol as a medicine cannot be long upheld by intelligent and well-informed physicians, who must discard it from their general practice. I have good reason for believing that our most eminent medical men are now using this dangerous article much more cautiously than they did but a few years ago; so that the thoughtful and educated men in the profession, who condemn its present free use as a medicine except in a few cases, are likely to increase in number and influence.

As you may not have seen Dr. Edmunds' address, I send you a Manchester paper which contains it. I thank you very heartily for the permission you have given me on several occasions of laying my ideas before your readers, and I hope you will add to the favours already conferred on me, by publishing this justification of my conduct, upon which you have animadverted.—Yours, very truly,

JAMES HAUGHTON.

[Mr. Haughton, on re-perusal of our observations, will observe that we accused certain Boards of Guardians of having "jumped at an unconsidered proposal to save money by refusing stimulants for the treatment of disease," and did not at all include him or Dr. Nicolls, whose motives we have every confidence in, in our censure. The value of Dr. Edmunds' opinion as a counterpoise to that of almost the entire scientific world may be estimated by the fact that that gentleman is, if we are not mistaken, a Professor in the *Female Medical College*. Ed. M. P. & C.]

**COD-LIVER OIL.**—The commercial reports sent in from time to time to the Foreign Office by our consuls abroad form a most useful element in that vast accumulation of statistical literature which is yearly printed at the national expense for the supply of members of Parliament with waste paper. A recently issued number contains carefully compiled reports on the fisheries of Norway and Iceland, and in an interesting notice in the *Saturday Review* it is stated that the yield of the oil so largely used in medicine varies a good deal from year to year, sometimes 300 livers being sufficient to make a barrel, while at other times as many as 500 are required for that purpose. In 1866 the Loffoden fishery supplied about 26,000 barrels of oil.

## THE LANCET

AND

## THE OBSTETRICAL SOCIETY OF LONDON.

OUR contemporary, the *Lancet*, has deemed it advisable to give a little wholesome advice to the Fellows of the Obstetrical Society as to the manner in which they should record their vote on a resolution of the Council for the expulsion of one of their members. We fondly hoped that the Medical Press would, at the present time, have stood aloof from offering any suggestions until they were in possession of certain "published matters" on which the proposed expulsion of one of the Fellows of this Society would rest. However, as the *Lancet* has thought proper to deal with the matter, and that in a way which, to our mind, indicates foregone conclusions and biased feelings, we think it is only in the interest of professional justice to express our sentiments on a subject which has such a bearing on the independence and honour of our profession. In the first place, then, we would say, that we are fully satisfied that the Fellows of the Obstetrical Society are quite alive themselves to the difficulties that surround them in coming to a decision, and doubt whether they receive with due gratitude the overweening, officious, mentor-like guardianship of the *Lancet*, and that they will smell when they read, in what is styled the "Medical Annotations" of that journal, "One word of advice to the Fellows." The advice so fragmentally introduced is as follows:—

"Their judgment should be formed ere they enter the room, and should be based upon a careful consideration of the "published matters" with which they will be supplied."

To us, we confess that this advice, so solemnly and judicially proffered, amounts in effect to this—Let the jury make up their minds privately and separately in their own homes, before they enter the jury-box. Let them not trouble themselves to hear what the accused, whose reputation and honour as a Surgeon, a gentleman, and an Englishman are at stake, has, by any possibility, to say in his defence; and further, let them make up their minds, not after hearing the summary of an unbiassed judge, but after reading a quantity of extracts from some published matters made by the accusers themselves, and brought together how, when, and as they please.

In the name of justice, in the name of our general professional honour, let the accusers of Mr. BROWN hesitate before they pursue their head-long career. If this thing is done without it be really in the interest of justice and necessity, it will be an eternal disgrace to the Society, and surely tend to reduce it from its present position to a clique, a monopoly, a coterie, which, like Athenian citizenship, would be dangerous to all men of character and reputation. By all means, then, let the jury who will have to acquit or condemn Mr. BROWN, consider the responsibilities of the situation they occupy. It is, we presume, more than probable that the charges brought against Mr. BROWN will be explained away, at any rate it is, we think, possible that the Fellows of this Society, may not come to the conclusion that Mr. BROWN is such a leper that to approach is to defile, and moreover, that if any doubt on the matter they will give the benefit of it to the accused.

Under any circumstances, the hot haste exhibited by the accusers seem quite unaccountable. To them, as to all other right minded men, the whole affair must be inexpressibly painful, and, however to their minds necessary in the interests of the profession, yet one would suppose a matter worthy of the utmost deliberation, and demanding especially every opportunity for the justification of the accused. However it be settled, whether Mr. BROWN be voted a Fellow or voted a nuisance, the stigma, the brand, the hot iron which is about to set its mark will not so readily cool. Mr. BROWN will be on his trial on the 3rd of April, and every tittle of evidence, *pro* and *con*, must be heard before any just decision can be arrived at.

We must ask leave to put in the pillory one other piece of advice in the same article. It is this. "If they (the fellows) hesitate, waiting for a decision from any discussion which may take place, *the business*, [the italics are ours], which ought without doubt to be definitely concluded at the meeting will stand a chance of being delayed." What!! the literary affairs of the Obstetrical Society to be of such prime importance, that they cannot be delayed for an evening, for an hour, when the character and reputation of one of its most celebrated members is at stake. Heaven save the mark!

Again, we are told that delay "would be unjust, both to the Fellow whose conduct is in question, and to the Council who have undertaken a most unenviable task from a conviction that the interests of the Society and the Profession at large demand vigorous proceedings at their hands."

This last paragraph we know nothing about, as we have not consulted the one or the other, but the "unenviable task" that we have to perform is to reproduce in our own columns these few annotations.

We cannot, however, conclude without expressing our astonishment that the "published matters" involve such considerable care in their arranging and printing.

We trust that when they *do* appear that they will not be so bulky as to prevent our criticisms on them in our next number.

## Medical News.

APOTHECARIES' HALL.—The following are the names of the gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, March 14:—

Charles Arthur Bush (St. Bartholomew's Hospital), Park-street, Bath.  
Alfred John Freeman (St. Thomas's Hospital), Southsea, Hants.  
Alfred Trubshaw (Liverpool), Royal Infirmary, Liverpool.

The following gentleman also on the same day passed his first examination:—

John William Pinder, Middlesex Hospital.

At a Meeting of the Fellows of the Royal College of Surgeons in Ireland, held, pursuant to Charter, on the 15th inst., Archibald Hamilton Jacob, M.D., F.R.C.S., was elected a Member of the Council of the College.

THE BAKER BROWN TESTIMONIAL.—The testimonial to be presented to Mr. Baker Brown, is now on view at Mr. Benson's, 25, Old Bond-street, by whom it was designed and manufactured. It consists of a silver dessert service of six pieces—centrepiece, plateau, and four fruit stands *en suite* of a very chaste classic pattern.

MEDICAL CHARITIES.—The Hon. Lady Caroline Murray, of Richmond, Surrey, has bequeathed £50 each to the Middlesex, London Fever, and Marylebone Hospitals; and £25 to the Royal Eye Infirmary. This lady has also bequeathed liberal sums to other charities not strictly medical.

OVARIOTOMY.—At a meeting of the committee of Queen Adelaide's Dispensary, Bethnal-green, held March 7, it was resolved that a room in the new building should be devoted to the above operation, under the care of Mr. Maunder, the consulting surgeon.

We understand that Dr. Struthers, Professor of Anatomy in the University of Aberdeen, late Lecturer on Anatomy, Edinburgh, is a candidate for the Chair of Anatomy in the University of Edinburgh, vacant by the death of Professor Goodsir.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.—Sixth Meeting, Session, 1866-67.—Wednesday, 20th March, 1867, tea at eight; chair to be taken at half-past eight, P.M. Communications.—1. Dr. Moore Madden—"A remarkable case of Psoas Abscess, with some observations on the treatment of the disease." 2. Dr. Law—"On Cerebro-spinal Arachnitis." 3. Dr. Hughes—"To exhibit, and make some observations on, a case of Pemphigus."

**THE STATISTICAL SOCIETY.**—Council and Officers for 1867-68.—President—\*The Right Honourable W. E. Gladstone, M.P. Council—\*Walter Bagehot, M.A.; Major-General Balfour, C.B.; \*R. Dudley Baxter, M.A.; Lord Belper; Sir John Boileau, Bart., F.R.S.; William John Bovil; Samuel Brown; William Camps, M.D.; David Chadwick; Leonard Henry Courtney; William Farr, M.D., D.C.L., F.R.S.; William Augustus Guy, M.B., F.R.S.; James Thomas Hammick; Frederick Hendriks; James Heywood, M.A., F.R.S.; William Barwick Hodge; Right Hon. Lord Houghton; Charles Jellicoe; Francis Jourdan; \*John Lambert; Leone Levi; William Golden Lumley, LL.M.; Matthew Henry Marsh, M.P.; William Newmarch, F.R.S.; Frederick Purdy; Rev. J. E. T. Rogers, M.A.; \*William Lucas Sargant; Col. W. H. Sykes, M.P., F.R.S.; \*Jacob Waley, M.A.; John Walter. Those marked \* are new members. Treasurer—William Farr, M.D., D.C.L., F.R.S. Honorary Secretaries—Wm. Augustus Guy, M.B., F.R.S.; William Golden Lumley, LL.M.; Frederick Purdy.

We are glad to observe a considerable increase in the amount taken this year in the army estimates for carrying out the Act (27 and 28 Vict., cap. 85) "for the prevention of contagious diseases at certain naval and military stations." Last year only £7000 was voted on this account. This year the vote has swelled to £28,271. The money is distributed between the following stations:—Chatham, London Lock Hospitals, and Woolwich, Aldershot, Windsor, Colchester, Shorncliffe, the Curragh, Cork, and Queenstown; a portion going to defray the expenses of the inspector and executive.

**CALOMBINE IN DYSPEPSIA**—WHITTSTOCK.—Exhaust Colombo-root with rectified alcohol, and evaporate to dryness the alcoholic solution so obtained. Treat this extract with water, and agitate it with an equal volume of ether. Draw off the ether with a syphon, distil off the greater part, and set the remainder aside to crystallize. Wash the crystals with cold ether, and press them in filter paper. The active principle of colombo *columbine* thus obtained is recommended in some forms of dyspepsia in doses of five to fifteen centigrammes daily.—*L'Union Medicale*.

**M. AUZIAS-TURENNE** adheres strongly to his own views, believing in the possibility of inoculating animals with syphilis. He is satisfied of this by his own experiments which, however, have not obtained general confidence. Our 'confrère' yesterday, he read the conclusion of the pathological history of a cat, that he had inoculated with syphilis, and of which he had some time since presented us with a short account. M. Ricord is not satisfied with this very complicated history, and he, with M. M. Bouley and Guérin, have asked for a commission to set at rest, finally, the question of the transmission of syphilis to animals. The Vaccine Commission appears to have determined that the inoculation of cows with syphilis has failed. The commission now asked for has just been nominated.—*L'Union Médicale*.

**OXALIC ACID** has been produced synthetically by M. Berthelot, by means of super-oxygenated acetylene placed in contact with permanganate of potash. This transformation is easy and prompt, and in considerable proportion. It is also certain that by causing permanganate of potash to act upon carburets analogous to acetylene, amylenes, and ethylene, many other equally interesting synthesis may be produced. This important discovery was announced at the meeting of the Academy of Sciences, at Paris, on the 7th inst.—*Comptes Rendus*, 1867, No. 1.

**MISS NIGHTINGALE ON TRAINING OF NURSES.**—

The committee recently appointed by the Poor-Law Board to advise upon the amount of space needed in metropolitan workhouse infirmaries, and upon other allied matters, requested Miss Nightingale to give her opinion and advice in relation to a supply of trained nurses for these infirmaries, and received from her a series of suggestions upon the subject. Miss Nightingale begins with observing that the word "nursing" is improving its meaning every year, and that what she proposes to treat of is "trained nursing"—that is, qualified nursing; "hired nurses, unless they are also trained nurses, are not worth their hire, except by accident." "An uneducated man who practises physic is justly called a quack, perhaps an impostor; why are not uneducated nurses called quacks and impostors? Simply, I suppose, because people have thought that every woman was a nurse by instinct." There is now a great movement over England and indeed the colonies also, the

object of which is to offer inducements to the best instead of the worst women, and to train them in nursing duties under matrons and head nurses (called in hospital language "sisters") as the basis for all nursing appointments whatever. Very few trained nurses are available for workhouse infirmaries; the demand is, and will be for years to come, far greater than the supply. To put one trained nurse, however efficient, in a large town workhouse infirmary is but to waste and throw away a valuable article; she either breaks her heart or becomes slovenly, like the rest, and neglects her duty. In small, well-managed country institutions, where the sick may be nursed by one good trained head nurse, it may do, otherwise no good can be done except in sending in (as at Liverpool Workhouse infirmary) a trained superintendent with a staff of trained head nurses under her. The principle at the training school at St. Thomas's is to train women and to certificate them, and then find employment for them, making the best bargain for them, not only as to wages, but as to arrangements and facilities for success; but at present the difficulty is to supply the demand or a tithe of the demand. Therefore, what Miss Nightingale advises is to complete a staff for one metropolitan workhouse infirmary, and make it a special duty of this staff to train nurses for other infirmaries—to make this one thoroughly complete from the beginning, and set in the right groove from the first, whatever intermediate course may be taken to supply meantime better nursing than at present in the other London workhouse infirmaries. The system adopted at St. Thomas's Hospital under the Nightingale Fund allows the probationers a stipend during their year of training, after which immediate employment is obtained for them, at present as hospital or infirmary nurses, commencing at not less than £20 a-year, with the usual extras; they are required to serve as such hospital nurses for four years, and this is the only recompense exacted for the costs and advantages of training. The principles are substantially the same under the life fund at King's College Hospital, where the training is for midwifery; owing to the great opportunity for this branch of practice in London workhouses the nurses there trained would find a considerable demand from ladies' committees and benevolent institutions, which pay them well. The probationers receive the requisite medical and surgical instruction, at the bedside or otherwise, from the medical professors or resident officers. Miss Nightingale discusses the details of a proper training, suggests two years of it for those who have to train others in their turn, and remarks that in course of time there might be a trained superintendent general for the whole of the metropolitan workhouse infirmaries, responsible directly to the Poor-Law Board. With wages given during training it is thought that fit women (above 25 years of age) will present themselves. They are not likely to be found among the inmates of workhouses, or at all events of London workhouses; but girls leaving the large union schools might be disposed to take hospital nursing, doing what they can in the children's and women's sick wards, and instructed in an industrial department, until the full-blown hospital nurse is developed out of them, when they would earn more than they could ever expect in domestic service. Miss Nightingale is decidedly against placing the nursing establishment under the workhouse master or matron, or the medical officer. In workhouse administration for the able-bodied, there is ever kept in view the necessity of checking the constant tendency of a certain class to fall into pauperism; but with the sick the best policy is to cure as quickly as possible. The two departments are to be conducted on different principles. Vest the general supervision and administration of the infirmary in a governor responsible to the board or committee; vest the whole responsibility for the nursing, the internal management, and the discipline of the nurses in the female head of the nursing staff, responsible to the constituted authorities. The orders of the medical officer are ever to be obeyed, but "in disciplinary matters a woman only can understand a woman." Miss Nightingale goes on to state the results of her experience in reference to the number of beds advisable per ward, the surface area required, and other matters. She notices that the larger the number of sick (up to 800 or 1000) under one hospital government and one matron, the better both for economy and efficiency. Without consolidation of workhouse hospitals a great and quite needless expenditure would have to be incurred in attempting to secure the conditions under which efficient nursing can be carried out. Her object is to include in the proposed arrangements those workhouse sick who are infirm and aged, including "helpless cases," "dirty cases;" "such require more careful nursing than any, and receive it at all good establishments for infirm and invalids both in England and abroad."

## Original Communications.

## THE TREATMENT OF EPILEPSY; PRINCIPLES AND PRACTICE.\*

By JOHN CHAPMAN, M.D., M.R.C.P., &amp;c.

AMONG the first approaches to a true conception of the nature of the proximate cause of epilepsy was that made by Dr. J. C. Pritchard, who, in 1822, published "A Treatise on Diseases of the Nervous System," in which he stated that "the immediate cause of an attack of epilepsy, or that physical change which, in a constitution prepared by natural predisposition, or by the action of morbid circumstances, is the immediate precursor and occasion of the fit, appears to be a preternatural influx of blood into the vessels of the encephalon, or an unusual fullness in some part of the vascular system of that organ." He was evidently led to this conclusion by his sagacious observations of the changes occurring in the diameters of arteries. Concerning their local dilatation and contraction he says:—"A person who doubts the possibility of a change of capacity in the vessels of one part, without any corresponding alteration in the general state of the circulation, may be convinced of it by plunging one arm into a vessel of hot water, and the other into a vessel of cold water at the same time. On again withdrawing his arm, he will find one somewhat larger than the other from the effect of distended vessels, with the external veins dilated and the pulse of the bronchial artery and its branches stronger and of greater volume than in the arm which has been immersed in cold water." Not only in his hypothesis of the nature of epilepsy but also in the reasoning by which he sustained it, Dr. Pritchard foreshadowed, to a wonderful extent, the doctrines of the most eminent pathologists of the present day. But even the most accurate observer, profound thinker or gifted genius, can rarely advance far in the path of discovery beyond the point attained by his scientific contemporaries: he is related to his age, and subject to its conditions. Before Dr. Pritchard's views of the general character and kinship of diseases of the nervous system could become fully developed, and before their fundamental truthfulness could be confirmed, our knowledge of the structure and functions of the nervous system needed to expand far beyond the dimensions it had reached at the time he wrote. Hence his hypothesis that the proximate cause of the majority of diseases of the nervous system consists in excessive local affluxes or effluxes of blood in the nervous centres, independently of any acceleration or retardation of the general circulation, could only take its place as one among the many "guesses at truth,"—a fortunate guess indeed, so far as it went, but incapable, when first expressed, of being proved either right or wrong.

So long as the spinal cord continued to be regarded as a mere bundle of conducting fibres—the inverted trunk of a nervous tree whose roots are in the brain and whose branches spread throughout the body, and so long as the spinal nerves were held to be single homogeneous structures, transmitting impressions from the periphery to the centre, and the mandates of the will from the centre to the periphery, it was impossible to divine, with certainty, the exact nature of a large group of diseases of the nervous system, and notably the nature of epilepsy. Until the individuality of the different columns, and of the several segments of the spinal cord, and the possibility of their independent action were recognized; until the era of positive knowledge of neural-physiology was inaugurated by Sir Charles Bell's great discovery of the two-fold or compound nature of each spinal nerve; until the automatic excitomotor functions of the cerebro-spinal axis, comprehending its afferent and efferent nerves, was demonstrated and immovably established on a scientific basis; and until the

function of the sympathetic, in so far as it presides over the contraction and dilatation of blood-vessels was determined, physicians engaged in the study of epilepsy were groping in the dark, or, at best, pursuing their enquiries in a dim half light, and were unable to frame any hypothesis affording a consistent and adequate explanation of the numerous and wonderful phenomena of that terrible, and for ages inscrutable, disease.

No single discovery in the vast domain of biology has contributed so greatly to demonstrate the exact nature of epilepsy as that made by Bernard when he ascertained the functional relation of the sympathetic nerve to the vascular system; while confirming that discovery experimentally, Brown Séquard at once appreciated its immense importance as a guiding light in the most obscure regions of pathology, and by its aid clearly explained the production of the loss of consciousness constituting the initial stage of a fit of epilepsy, as well as the phenomenon of *le petit mal*. By demonstrating the great rôle played in a fit of epilepsy by what he called "the true spinal cord," Dr. Marshall Hall did much towards building up the correct hypothesis of the disease; but it was impossible that his doctrine concerning the functions of "the true spinal cord" could suggest more than the half of that hypothesis: it could only be completed when at length the nature and extent of the controlling influence exercised by the great nerve of organic life—as Bichat called the sympathetic—over the whole vascular system, and therefore over the nutrition and vitality of the organism, became perfectly understood.

The doctrine concerning the seat and nature of epilepsy now recognised as true by the most eminent neuro-pathologists has been of long and slow growth, and is the product of the observations, experiments, and elaborate reasoning of many distinguished men; but it is, I believe, generally admitted that no one has contributed so largely to develop and illustrate that doctrine as Brown Séquard. I do not purpose at present to give a critical exposition of it, but merely to state it in order to indicate that treatment of epilepsy and epileptoid affections, which is the logical consequence of its acceptance. "Epilepsy," says Dr. Brown Séquard, "seems to consist essentially in an increased reflex excitability of certain parts of the cerebro-spinal axis, and in a loss of the control that in normal conditions the will possesses over the reflex faculty;" and he has shown how this state of "increased reflex excitability" being propagated to those sympathetic nervous centres controlling the arteries of the brain, results in inducing contraction of those arteries, and the consequent loss of consciousness which ushers in an epileptic fit. Dr. Russell Reynolds is an able exponent of this doctrine, and in his comprehensive and elaborate work on epilepsy expresses it as follows:—"Augmented activity in the nutritive process of the medulla oblongata and spinalis is the prime and essential fact in epilepsy; it needs the addition of but an 'exciting cause' to set in motion the whole train of phenomena which constitute the attack" (p. 260). And again he says:—"The immediate cause of epilepsy is over action of the reflective centre, from increased vascular supply, and exaggerated nutrition, change" (p. 264). This doctrine, as is well known, receives confirmation from the experimental investigations of Kussmaul and Tenner, as well as from the microscopical dissections of Schroder van der Kolk, who concludes that "the first course of epilepsy consists in an exalted sensibility and excitability of the medulla oblongata, rendering the latter liable to discharge itself on the application of several irritants, which excite involuntary reflex movements." Although it is not now my intention to adduce any arguments in support of these views, or to submit them to critical examination, I may observe, in passing, that my experience has afforded me good reasons for believing that their advocates locate the primary seat of epilepsy too exclusively in the medulla oblongata. Both Brown Séquard, and Dr. Russell Reynolds, do indeed say that that modification in the nutrition and function of the nervous structure, resulting in epilepsy, may occur in the spinal cord, but their writings imply that as a matter of

\* A Paper read at the Medical Society of London, March 18th, 1867.

fact it does occur much less frequently there than, as I believe, is actually the case. My observations and experiments constrain me to infer that the spinal cord, especially the lower third of it, is very frequently the seat of those morbid changes which induce the disease. Assuming that the pathology of epilepsy here adverted to is in the main correct, it is clear that the only rational and scientific treatment of the disease must consist—(1) in discovering and removing all causes of eccentric irritation, and (2) in exerting a sedative influence on the nervous centres primarily implicated, either by direct action on those parts, or indirectly on the principle of "derivation." Accordingly, Dr. Brown Séquard, when speaking of drugs likely to be most efficacious, recommends "particularly those which determine contractions" of the blood-vessels of the nervous centres, "such as atropia, ergot of rye, &c." In his lecture on epilepsy he said, "Iron should be avoided unless the fits be due to anæmia or chlorosis. Iron causes alterations of the circulation in the brain of a kind not conducive to the cure of epilepsy." He prescribed bromide of potassium largely, but empirically, for he found its influence beneficial, although respecting its exact *modus operandi*, he had, as he stated to me, no distinct knowledge. In his lecture just mentioned he said, that "when it is taken in large doses for a considerable time, it causes congestion of the brain, and loss of feeling in the urethra, and probably in the seminal vessels. That it causes this loss of feeling is, I believe, an established fact; but experiments, which I shall presently mention, prove that instead of causing congestion it causes anæmia of the brain. Thus, it appears, that both in principle and practice the treatment of epilepsy by this distinguished man, aimed to exert a sedative influence on the nervous centres; and Dr. Russell Reynolds in his chapter on treatment, regards as the first requisite, "the reduction of undue excitability in the reflex centre," and passes in review the several medicines believed to be most conducive to this end.

But just as the thick clouds which have hung over this subject for ages seem to be dispersing—just as we appear to be forming correct conceptions of the whole region of neuro-pathology, and under their guidance to be steadily developing the principles and method of a scientific treatment of diseases of the nervous system in general, and of epilepsy in particular—we are told that we are the victims of the most complete delusion; that the pathology of convulsive affections, of paralysis, and even of pain, as well as the therapeutical principles and practices founded upon that pathology, is but an ingenious and elaborate dream, which, according to the laws of dream-interpretation, is exactly the reverse of the truth. Dr. Bland Radcliffe, in his lecture delivered to the Royal College of Physicians, has proved, as he maintains, by an irrefragible chain of arguments, illustrated by a series of complicated electrical experiments, that "there is reason to believe that ordinary muscular contraction is associated with deprivation of nervous influence, and not with a contrary state of things.

The logical inference from this doctrine is, of course, that convulsive and spasmodic affections generally are consequences and symptoms of a deficiency of nervous energy in the nervous centres presiding over the muscular system. At the end of his fifth lecture Dr. Radcliffe says—"All the previous considerations lead to this conclusion, and to this conclusion only." And, accordingly, he is led by his peculiar pathology of these affections to declare that "there is reason to believe" that their most successful treatment consists in strengthening the nervous system by every possible means; that the diet of epileptic persons should contain "somewhat more than an average quantity of oily and fatty matters;" that "cod liver oil is very beneficial;" that "alcoholic stimulants are very trustworthy antispasmodic in the prevention and treatment of convulsions;" that "opium may be a more suitable remedy than belladonna;" and that "phosphorous may be given, not only without harm, but with the unmistakable promise of real and substantial good."

As might be expected, these doctrines find no favour in the eyes of the exponents of the hypothesis previously men-

tioned; indeed, they seem to think it deserving of only so much attention as may be given to it in a momentary glance. Dr. Russell Reynolds says in a note—"This hypothesis is, in my opinion, incorrect; but except so far as bears directly upon the pathology of epilepsy, a discussion of its merits cannot be entered on here;" and this special discussion he confines to fifteen lines. Dr. Brown Séquard expresses himself as follows:—"It is useless to discuss a theory like this, which is in opposition to almost all the known and the most positive facts of physiology and pathology. I will merely say that if the theory were true, we should always see convulsions in paralysed muscles, and also after death, at the time when nerves lose their power upon muscles."

I think, however, that the indefatigable labour, the extensive knowledge, and the ingenuity which Dr. Radcliffe has brought to bear in support of his doctrine, entitle it to somewhat fuller consideration than has been accorded to it. I shall, therefore, even in this brief essay, say a few words concerning it. After examining many of the chief facts on which he relies in corroboration of his theory, I have satisfied myself that they are susceptible of explanation in a manner quite different from that which he has adopted, and that, rightly interpreted, they lead to a conclusion, both theoretical and practical, diametrically opposite to that at which he has arrived. But to follow him throughout his course of labyrinthine reasoning, and to point out what I conceive to be its errors; to advert to all the facts he adduces, and to show, not only how they have been misapplied, but what is their true significance; to disentangle the truth from the error to which he has made it subservient; and to exhibit the grave practical mistakes in the treatment of disease which his, as I believe, false physiological and pathological theories must inevitably lead him, if he faithfully follows them, I should be obliged to fill the pages of a volume as large as his own. But often, as in this instance, it is more expedient to cut a knot than to spend time in untying it, and I hope to do this by merely stating a number of facts which are thoroughly established, and which, in my opinion, prove that Dr. Radcliffe's doctrines are entirely erroneous.

Of course I presume it will be freely admitted that when ice is applied over a nervous centre, if the influence of the cold reaches directly to that centre at all, it causes its blood-vessels to contract, lessens the amount of blood in it, and, to a proportionate degree, lessens its vitality and functional energy; and that, conversely, when heat is applied over a nervous centre, it causes the blood-vessels of that centre to relax, increases the amount of blood in it, and to a proportionate degree its vitality and functional energy. We know cold and heat applied to the head act respectively on the brain in the manner here stated, and we know that, within certain limits, by taking heat from or adding it to organic structures generally, their vital properties and functional activity will be correspondingly depressed or exalted. There is, therefore, I apprehend, no possibility of escape from the conclusion that if cold and heat applied along the spine exert any direct influence on the spinal and sympathetic nervous centres, cold acts upon them as a powerful sedative, and heat as a not less powerful stimulant. Now, I have ascertained that by exerting the sedative influence of cold on nervous centres, the vigour and activity of the muscles they govern are lessened, and that, conversely, by exerting the stimulating influence of heat on nervous centres, the vigour and activity of the muscles they govern are increased. By an extensive experience I have verified the following facts:—

*First*, In cases of cramp or spasms of voluntary muscles, the application of ice over the spinal nervous centres related to the muscles affected will cause the cramp or spasms to subside. The cramps of cholera, diarrhoea, sea-sickness, and the ordinary cramp experienced at night by many persons otherwise fairly healthy, as well as the abnormal contraction of voluntary muscles in many other cases, may be subdued by this method properly applied. Moreover, the convulsive spasms of laryngismus stridulus may be arrested in the same way, and even the tonic convulsions

of a strong epileptic fit may thus be greatly lessened both in force and duration.

*Second,* That at least some epileptic patients are predisposed to have fits by the application of heat along the spine. [The reason, no doubt, why heat along the spine does not induce action of the voluntary muscles is, that the will, which holds them quiescent, is the predominant power. Epileptics, whose tendencies to convulsive movements are increased by heat along the spine, do not show these tendencies, but complain that they have "fit feelings." I apprehend that if heat could be adequately applied along the spine of a sleeping patient without waking him, the will, being then in abeyance, would permit those tendencies to develop themselves: heat along the spine affects the sympathetic ganglia as well as the spinal cord; and if the heat were applied to the upper third of the spine, cerebral anæmia might be induced to such an extent as to result in loss of consciousness, which, if not the indispensable condition precedent, is, at all events, the most favourable condition for the production of convulsions, which, therefore, would most likely supervene.]

*Third,* In cases of spasm of involuntary muscles the application of ice over the nervous centres related to the muscles affected will cause those muscles to relax. Spasms or undue contraction of the cerebral arteries causing fainting fits; excessive contraction of the dilatator muscle of the iris, causing an abnormally large pupil; spasm of the central artery of the retina producing weakness of sight (amblyopia), or blindness (amaurosis); spasm of the arteries of the face, causing partial anæsthesia or impairment of tractile sensibility; simultaneous and undue contraction of the bronchial tubes, and of the pulmonary blood-vessels, constituting a not uncommon form of dyspnoea, and, as I maintain, a distinguishing feature of cholera; undue contraction of the gastric and mesenteric arteries, preventing an adequate supply of blood from reaching the stomach and bowels, and resulting very frequently in indigestion and constipation; spasm of the uterine (and probably of the ovarian arteries) producing deficient menstrual flux, dysmenorrhœa, and amenorrhœa; spasm of the arteries of the lower extremities producing, habitual coldness of the feet even in summer, may all be overcome—the unduly contracted arteries in each case being relaxed, and the disease consequent on their excessive contraction cured—by the application of ice over the appropriate parts of the spine.

*Fourth,* Involuntary muscles unduly relaxed may be made to contract by the application of heat over the nervous centres related to the muscles affected. Excessive relaxation of the muscular coat of the cerebral arteries permitting their abnormal dilatation, and resulting in hyperæmic headache, or cerebral congestion with contracted pupil; excessive relaxation of the central artery of the retina producing congestive amaurosis; excessive relaxation of the pulmonary blood-vessels producing pulmonary congestion (which causes dyspnoea, but of a kind opposite to that previously mentioned), and also pulmonary hemorrhage; excessive relaxation of the mesenteric arteries, resulting in intestinal hæmorrhage; and excessive relaxation of the uterine arteries resulting in menorrhagia, may all be counteracted, the muscular coats of the relaxed arteries being made to contract, and the diseases consequent on their relaxation cured, by the proper application of heat over the nervous centres related to any special group of arteries in question. It is also equally certain that in many cases, at all events, feet habitually warm may be made cold; in other words, that the arteries of the lower extremities may be contracted by the application of heat along each side of the lumbar segments of the spine.

Now, if these statements are true (and I may observe that I can call professional witnesses to confirm nearly every one of them) they prove beyond the possibility of contradiction, as it seems to me, that ordinary muscular contraction is immediately due to the presence and stimulating action of nervous force, that the energy of muscular contraction is directly proportionate to the amount of that force expended on the contracting muscles, and that, there-

fore, Dr. Bland Radcliffe's dictum—viz., that "there is reason to believe that ordinary muscular contraction is associated with the deprivation of nervous influence, and not with a contrary state of things," is completely confuted and proved to be diametrically opposite to the truth by a large number of pathological experiments which each physician can verify for himself.

As already stated, Dr. Radcliffe's pathology of convulsive affections, and the principles which he asserts ought to become our guides in treating them, are the logical consequences of his doctrine of the functional relations of the nervous to the muscular system; it is evident, therefore, that if that doctrine is proved to be untrue, the whole pathological and therapeutical system evolved from it is untrue also. If so, it is obvious that the sooner the practical application of the system is abandoned the better; for methods of treatment diametrically opposite to those dictated by correct physiological and pathological principles while proving unsuccessful may, in some cases, be attended with danger. Indeed, I am glad to be able to say that practically the theory in question has been given up by Dr. Bland Radcliffe himself. While at its bidding he says—"there is reason to believe that the therapeutics of convulsion must be based upon the notion that vital power has to be reinforced," he, in his last published volume, wholly ignores the use of iron for this purpose in the treatment of epilepsy. This is the more remarkable, as in his lectures delivered at the College of Physicians, and which are said to constitute this volume, he (if my memory is not very treacherous) complimented the President, Sir Thomas Watson, on his wisdom in prescribing iron in cases of epilepsy, on the ground that this practice truly foreshadowed "the therapeutics of convulsion," which the lecturer's theory had at length fully revealed. What can be the reason, it will be asked, for this astonishing omission of iron—one of the most powerful agents which can be employed when "vital power has to be reinforced"—from the list of remedies mentioned by Dr. Radcliffe in his revised and published lectures? The answer is simple, the omission is merely one of the many instances in which, in his practice, the philosopher is faithless to his principles. As a matter of fact Dr. Radcliffe found that iron does not prove beneficial to epileptics, and therefore despite his hypothesis he has ceased to prescribe it. But this practical desertion of his therapeutical doctrine is very far from denoting the full measure of his infidelity: it is in the copious administration of bromide of potassium, that he shows implicitly his complete abandonment of his long cherished theory.

The experiments of Dr. Hammond, of New York, prove that this salt exerts an extraordinary power in lessening the circulation of the blood in, and therefore the nutrition and vigour of the brain. A French physician, whose name I cannot now recall, has published evidence that in many cases this same drug lessens the virile power so effectively as in some cases to abolish it; and Dr. Radcliffe, himself, quotes from Dr. Pereira's "Materia Medica" the following remarkable testimony to the powerfully sedative and devitalizing effects on the nervous system of bromide of potassium. M. Huette states, he says, "that this compound possesses narcotic and anæsthetic powers of a very peculiar and energetic kind; if from three to four ounces, in doses gradually increased from ten to twenty scruples, be taken within a period of fifteen days, a dull headache is the first effect; stupor and drowsiness soon follow. This is interrupted by delirium, resembling the incoherence of idioty, mingled with hallucinations. The muscular strength rapidly gives way, and with it the general sensibility. The latter effect, however, is very seldom carried to any considerable degree, and the cases in which the bromide causes sufficient insensibility to admit of surgical operation being performed are very rare. It cannot, therefore, replace ether or chloroform. The symptoms above-described continue as long as the use of the medicine; but the functions of organic life are not changed, and the effects rapidly subside under the use of purgatives. One effect is peculiar: even in small doses it rapidly and completely annihilates the sensibility of the pharynx and

velum palati to such an extent that these parts may be tickled without exciting the least effort at deglutition." Dr. Bland Radcliffe then adds:—"This latter effect is not unfrequently produced by the doses necessary to produce a favourable impression in cases of epilepsy, by doses say of fifteen grains, three times a-day, and therefore it is possible that it may be necessary to assume some specific action upon the medulla oblongata, or upon the nerves belonging to this centre, in order to explain the *modus operandi* of the bromide."

Such is the medicine given by Dr. Radcliffe in cases when, according to his teaching, "vital power has to be reinforced." I need scarcely say, with what peculiar satisfaction I observe, in this instance, how greatly the doctor transcends his doctrine. "Consistency," says Emerson, "is the hobgoblin of little minds;" happily it has not terrified Dr. Radcliffe: when going to battle with convulsive affections, he bravely strips himself of his theory, leaves it behind him, and as his chief weapon, puts his trust in one of the most powerful *sedatives* of the nervous system.

(To be continued.)

## CONTRIBUTIONS TO CLINICAL SURGERY.

By WILLIAM HARGRAVE,

SURGEON TO THE CITY OF DUBLIN HOSPITAL, PROFESSOR OF SURGERY,  
MEMBER OF COUNCIL AND EX-PRESIDENT OF THE ROYAL COLLEGE OF  
SURGEONS.

### TETANUS FOLLOWING AMPUTATION OF THE BREAST IN THE FEMALE.

Reported by the Resident Pupil, Mr. CHARLES G. LYSTER.

Case 1.—Anne B., æt. 48 years; married; had six children, all healthy; occupation, washerwoman; residence in Great Clarence-place; always had been a healthy woman. Catamenia regular till the time of its ceasing about seven years ago; was always a very temperate person, never knew of cancer to have attacked any one of her relatives. Admitted into the City of Dublin Hospital on the 29th June, 1866. Previous to being admitted she came to the dispensary to get advice for her right arm and side, which, for some time past, had been becoming more and more numb. She then mentioned to Dr. Hargrave about the lump in her breast, when he at once pronounced it as that of cancer, and took her under his care.

The tumour, on examination, presented a very hard appearance, and involved the entire of the left mamma. There were several large veins crossing down the breast, and presenting a very livid appearance, also congested. It first came on by a small kernel about the size of a nut, more than two years ago. Never experienced any pain in the seat of the disease, till within about the last five weeks, when she occasionally had slight lancinating stings now and then through the affected breast. The nipple has a hard indurated appearance, and is on a level with the surrounding parts.

July 6th.—The patient being placed successfully under the influence of chloroform, and not by a large dose, the tumour was removed by Dr. Hargrave by two semilunar incisions which commenced high up in the axilla, and enabled him to remove with rapidity the entire breast; he next extirpated *all* the glands in the axilla, which exposed the axillary surface of the capsule of the shoulder joint. After the operation the wound was freely sponged with a solution of chloride of zinc, scruple ad unciam *aq.*, which caused no distress. An opiate draught of *mur. morphæ* with *sp. am. arom. syrup* and camphor julep was administered; when in bed pulse 72, and quite composed. The patient continued to improve most satisfactorily for *ten days* after the operation; pulse ranging from 96 to 110; natural as to rhythm, beat, and fulness; the wound was daily dressed, with sponge compresses, effectually preventing the lodgment of matter in the axilla; diet six ounces of wine daily, strong beef tea, and occasionally a chop for dinner; egg, tea with bread and butter for breakfast, and tea and bread and butter at night; an anodyne every night *træ opii, spiriti am. arom. træ zingiberis* and camphor julep.

On the 15th of July, nine days after the operation, unfavourable symptoms set in. In the morning they began by the patient complaining of great weakness, accompanied by a stiffness in her neck, which Dr. Hargrave at once pronounced to be the decided symptoms of tetanus. The next morning, the *tenth* from the operation, the case was a well marked one of traumatic tetanus. The sterno cleido mastoid muscles have become very rigid. She was ordered the following pills, one to be taken every third hour:—

℞ Ext. cannabis indicæ, gr. vi.

Pul. camph. redact. gr. ix. M.

Fiat massa in pilulas sex div cap i. tertiis horis.

She was ordered tobacco stupes over the abdomen, and opium ones over the wounded surface.

The patient found it impossible to swallow the pills, so she was ordered the following bolus, to be placed on the root of her tongue:—

℞ Pul. calomelanos, gr. ij.

„ Dover, gr. ij.

„ James, gr. ij. fiat bolus, ss.

She got enemas of strong beef tea, with a tablespoonful of whiskey to three ounces, to be repeated every three hours, also twenty grains of tobacco made into an infusion with eight ounces of water;  $\frac{ʒj.$  of this to be given per rectum every hour.

On the 16th of July almost all the muscles became rigid. The countenance has assumed that haggard and anxious appearance generally accompanying tetanus. Dr. Hargrave seeing that the treatment so far had little or no effect on the progress of the disease, put her under the influence of chloroform, which had a most decided effect over the jerkings of the muscles; he also directed the application of pounded ice and salt by means of the cesophagus of an ox, along the spine, which was maintained for three hours, the ice being renewed according as it melted; pulse now 118; the appearance and character of the risus sardonius, well marked.

17th.—Thirty drops of cannabis ind. were administered in an enema; the disease unchecked terminating fatally at half-past three p.m. of this day.

The extreme rarity of tetanus following a surgical operation, in which no violence or unusual delay occurred, or loss of blood to any amount, fully justifies me in placing it on record. The history of the case was carefully noted by Mr. Lyster, and Mr. Nason, my dresser, the treatment after the operation by the former.

The occurrence of such a fatal complication was not anticipated by me, constituting one of the very rare cases of this affection (as recorded) following a clean cut wound. S. Cooper mentions a case following a similar operation of amputation of the breast; also the case of the Earl of Darnley, who chopped off two of his toes with a clean hatchet; also following a few cases of amputation of a limb, and one case of castration. This patient, who had always led a very temperate life, combined with unceasing industry as a washerwoman till the day of her admission into hospital, and the mother of six children; her *morale* was good; she was perfectly satisfied with the proposed operation. The extent of the incisions were considerable, passing far and high into the axilla, of *necessity* to facilitate the removal of the glands, which were all filled with cancerous deposits, though their external surfaces presented the appearance of healthy lymphatic glands, all of them were extirpated. The wound was well sponged with the solution of chloride of zinc to destroy any cancer cell that might have escaped the knife; no uneasiness was experienced from the application. Everything went on most promisingly till the day specified in the report, the *tenth* from the operation; the wound casting off a very superficial thin slough three days after the operation, which was produced by the chloride of zinc lotion, then presenting a most healthy surface discharging healthy pus. On the *tenth* day symptoms of tetanus began to be evident, gradually extending from the masseters and sterno-mastoid muscles till those of the trunk and extremities were affected. But a remarkable exception and contrast

in the intensity, severity, and duration of the spasms of the superior extremities was observed.

Those on the right side were comparatively feebly affected, while the opposite one was to a much greater degree; of the muscles of the left side the intensity of the spasms were concentrated on the muscles of the scapula, especially the serratus mag. anticus m., which consisted of incessant and rapid jerkings, with very short intermissions. For the twenty-four hours preceding dissolution the spasmodic actions of the serratus mag. anticus and levator anguli scapulae were incessant in elevating the shoulder. Except the temporary check following the administration of chloroform, these spasms were more the character of rapid jerkings than what is expressed by the term spasm.

The treatment proved the effects of cannibis indica, and tobacco enemata with it were nil, but the tobacco stupe applied to the abdomen caused a temporary relaxation in the muscles of the inferior maxilla. For the first time in treating this affection I directed cold by means of pounded ice to be applied to the spine, from the nape of the neck to the sacrum. It was very effectually managed by filling not to distension the oesophagus of an ox. Under its application the muscles of the lower jaw were so relaxed that the patient could open her mouth and take some nourishment and medicine, from which I augured favourably; but I was doomed to be disappointed, as the oesophagus burst during the night. When visited in the morning the cold was discontinued for want of a proper means for its application. From the partial benefit experienced in this case from the application of ice, every hospital can be independent of the tube afforded by the means now mentioned, by directing any of the vulcanised India-rubber houses to make a tube of that material, which can be rendered water-tight, sufficiently strong, and so thin as not to prevent the effects of cold. It is difficult to explain such a fatal termination to a clean incised wound. Could the weather have any influence? it being at the time intensely and most oppressively hot. Still, she was always carefully protected from a chill when the wound was being dressed.

**MOST EXTENSIVE ECCHYMOsis, AND SANGUINEOUS DEPOSIT, CAUSED BY A CRUSHING INJURY.**

*Case 2.* William C., aged 48 years, married, occupation a carpenter, was admitted into City of Dublin Hospital on the 19th of June, 1866, suffering from the effects of a severe crushing he got between the step of a railway carriage and an adjacent wall at Kingstown.

On admission to hospital he complained of very great pain in his right hip, he also lost complete use of both inferior limbs, having no power to move them.

Dr. Hargrave saw him immediately after admission, and ordered the following liniment to be rubbed well into the side:

℞ Linimentum opii ꝑiii.  
Tinct. Canth. ꝑij.  
Chlorof. ꝑi.

Fiat. Linimentum.

He was also ordered a turpentine enema ss.

This treatment offered a perfect cure, as to the affection of the limbs, but then appeared an unusually large ecchymosis extending from the last rib to the thigh. After the discolourization had disappeared, a large fluctuating bag was found, which contained extravasated blood, extending from the last rib to the middle third of the thigh, and across from the coceyx to the groin. Was ordered

℞ Submur Hyd. gr. iii.  
Pul. Antimo. g. ii.  
Jalapae ꝑss. ℥.

Ut fiat pul. capiatur hora meridiana.

Cold applications were, in the first instance, applied to this large sanguineous tumour, which were found after a few days to in no way benefit or reduce the size of it; but produced a degree of chilliness, of which the patient complained, rendering him uncomfortable. This application was changed for the following one—cotton wadding, suffi-

ciently large to cover the entire of the tumour, was well soaked in olive oil, then applied to it, covered with gutta-percha tissue, all well supported by a broad flannel pelvic and femoral bandage; from this dressing the patient experienced much relief, and never after suffered from any chill; it was continued daily for one week, then every second one for another week, finally every seventy-two hours, till he was discharged. This treatment had the desired effect in completely causing the absorption of the entire of the effused blood into this sanguineous sac or bag; after five weeks of the application of the cotton wadding and oil, the patient left the hospital quite recovered.

Sanguineous tumours of the magnitude presented by this patient are of rare occurrence, and that without injury being inflicted on the integuments; the elasticity, strength, and toughness preserving their integrity, but, from the nature of the injury, causing them to glide over the subjacent tissues, as the cellular membrane and fibrous structures; a large detachment of the former is thus separated from the latter, leaving an empty cavity, which is immediately filled with extravasated blood and serum.

This case is valuable, not alone in its pathological characters, but also in enforcing the practical precept—*e.g.*, when cold applications are disagreeable to the patient's feelings, *though no chill* accompanies them, to change to those of the opposite kind, which, as the rule, are attended with satisfactory and successful results.

**COMPOUND FRACTURE OF THE TIBIA AND FIBULA, PRESENTING AN UNUSUAL RESULT.**

*Case 3.* John M., aged 21 years; single; residence 9, Denzille-street, was admitted into City of Dublin Hospital on the 21st June, 1866, suffering from a compound fracture of the tibia and fibula.

*History of Accident.*—He states that in the act of making a jump from off a bridge some sixteen feet high, his right foot was caught in a railing that was attached to the bridge, in so doing he lost his balance, and in trying to recover it he came with all his might on his left leg, not having had sufficient time to get the right foot under him. He received a compound fracture of both bones at the upper part of the lower third; when he was admitted to hospital the tibia was protruding through the skin. The limb was put up in McIntyre's splint. After a few days a large slough came away, and a large piece of the tibia, in size as large as a five-shilling piece became exposed. After some time straw splints were applied to the side of the limb.

The wound was dressed every day with the following ointment:—

℞ Balsami Peruviani, ꝑss.  
Tinct. opii, ꝑss.  
Ungt. Cetacei, ꝑss. ℥.

Fiat Ungt.

On the 22nd July, thirty days after the accident, complete union of both bones had taken place, though the ulcer on the leg is still very large, and the bones appear as if they were going to throw off a sequestrum. The limb is now slung in the cradle. The patient never complained of pain in the limb, and has got up flesh considerably since his admission into hospital.

Aug. 15th.—The ulcer is gradually getting smaller. Complete union has taken place. Not the least deformity.

25th.—There was nitric acid applied to the bone to-day.

26th.—A great improvement by the nitric acid; bones throwing out healthy granulations. No appearance of exfoliation taking place.

Sept. 1.—Wound quite covered now with granulations. Patient getting on most satisfactorily.

This case presents a remarkable exception to the general experience derived from observing the phenomena of union in compound fractures, which necessitates the wound being healed before osseous consolidation takes place. In this instance union was obtained many weeks before the ulcer was healed, resulting from the compound fracture and the bones covered in by granulations, it being completed in thirty-one days from June 21st to July 22nd,

while the ulcer was not healed till the middle of September, when he left the hospital with a sound and strong leg.

In the modern treatment of fractures of the inferior extremities, much advantage and benefit have been obtained by slinging the fractured limb, which enables the patient to sit up with great comfort to himself, and protecting the pulmonary and cranial organs from congestions, sometimes followed by fatal results. This practice is considered by many to have been introduced by Mayor, of Geneva, about thirty years ago, and named by him *hyponarthrasy*; but it is really derived from Hippocrates, who practised and described it, which, after a lapse of more than two thousand years, has been introduced to the Profession by the Swiss Surgeon.—(*Vide Hippocrates' Works*, vol. ii., p. 485).

## Lectures.

### THE CROONIAN LECTURES

DELIVERED AT THE

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

By Dr. ANDREW CLARK.

#### ABSTRACT OF LECTURE II.

DELIVERED FRIDAY, 15TH MARCH.

THE lecturer began by saying that the "grey granulation," plus the secondary local effects induced by it, constituted the complex state of lung characteristic of true tubercular phthisis. These effects were pneumonia, fibrous degeneration, fatty usure, and emphysema. By one or other, or several combined, the destruction of the tubercular lung was effected. There was no such thing as tubercular infiltration. The various forms of what was so designated were nothing more than the products of two different species of pneumonia. By itself, the grey granulation never killed. As we could avert its secondary effects, so could we retard the progress of the local disease, and prolong the patient's life.

In describing the microscopic characters of pulmonary "grey granulation," as seen *in situ*, Dr. Clark dwelt upon its correspondence to a vascular territory, its occasional capsulation by fibrous tissue, the appearance of a matrix suggestive of exudation, the presence of black pigment, the remarkable condition of the neighbouring lymphatics and blood-vessels, and the existence in the adjacent alveoli of proliferating cell-forms different from anything composing the granulation, and averred that no theory of the structural origin of tubercle could be satisfactory which did not account for these things. Dr. Clark next enumerated the elementary structural constituents of tubercle, and laid great stress on the presence of three different sorts of corpuscular or nuclear-like particles resembling the nuclei of epithelium, connective tissue and vessel, and on the comparative absence of fully-formed cells, the number of which held a direct relation to the youth of the patient, and the rapidity of the process of evolution. He then discussed, at length, the various theories by which the origin of the structural forms of the granulation was sought to be accounted for. To the exudation theory he objected that structural forms were found before any appearance of exudation; to Lebert's theory, that similar structural forms (though not in the same combinations or conditions) were found in non-tubercular products; to the epithelial theory, that the granulation arose often in parts where no epithelium was present—that in the young pulmonary granulation cells were absent, and that the epithelium-like cells existing in such numbers in the adjacent alveoli gave birth, not to a grey granulation, but to a cheesy deposit; and to Virchow's theory of the origin of the granulation in the exclusively endogenous proliferation of connective tissue corpuscles, he objected, on the score of error and inadequacy, but held that the theory embodied sufficient truth to form a cardinal element in another hypothesis.

Dr. Clark ascribed the structural origin of the granulation to the multiplication by division of the nuclear elements of all the tissues involved (but mainly of the lymphatics and blood-vessels), followed by exudation and occurring within the limits of an ultimate vascular territory. In the pulmonary alveoli he considered the order of local events to be as follows:—Rapid desquamation of epithelium, assuming its existence with liberation of nuclei; proliferation of *inter-capillary nuclei*, and of nuclei of the lymphatics and blood-vessels; differentiation of vascular wall back to point where terminal artery splits into capillaries; appearance of matrix by exudation, sometimes filling up the parts like wax, which has been poured, when melted, into a mould; occasional extravasation of blood, not unfrequently the development of a rude fibroid tissue around the granulation, which ceases to grow when it has fully occupied a vascular territory.

Dr. Clark considered that this order of events was set agoing by the transference to the part through the medium of the blood of the organic irritant operating under certain collateral conditions, such as certain constitutional states, deficient vascular distension, and imperfect expansion of lung.

Dr. Clark, before discussing the intimate nature of tubercle and its artificial induction by inoculation, venous injections, and the like, proceeded to consider the secondary local effects induced by the grey granulation.

Pneumonia was the chief agent of destruction in the phthisical lung. There were two forms of it: one, the rarer, in which the products of it were composed of particles like the colourless corpuscles of the blood; the other, the commoner, composed chiefly of epithelium-like cells in a state of active endogenous growth. The moleculo-fatty degeneration of these products to their epithelial character and to obliteration of adjacent blood-vessels and lymphatics. There were two forms of fibrous degeneration—one in which the tissue was well developed and abundantly nucleated, the other in which it was imperfectly developed. The particular form was determined by the habits, occupation, or constitution of the patient. Cases in which this degeneration took the lead were very slow in their progress, and extended over years. The fibrous degeneration began around the granulation or in the areolar tissue of neighbouring bronchi or blood-vessels, and from thence stole in upon the lung in various directions, leaving islets of alveoli, which underwent cheesy degeneration, and looked like yellow tubercles. Fatty usure was next described as indicated by the presence of white creamy-like deposits, of the size and form of caraway-seeds. It consisted of the transformation of accumulated epithelium-like cell into various-sized droplets of fluid fat, and usually issued in emphysema. The emphysema around tubercles Dr. Clark declared to be not dynamic or mechanical, but static or pathological. He did not deny the existence of a mere compensatory or mechanical emphysema, but declared his conviction, based upon experiment, that the majority of cases of emphysema were due to local structural changes in the alveoli, which he described.

## LUMLEIAN LECTURES

DELIVERED AT THE

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

By J. RUSSELL REYNOLDS, M.D.,

HOLME PROFESSOR OF CLINICAL MEDICINE IN UNIVERSITY COLLEGE, AND PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

### LECTURE I.

THE object of the lecturer was to show—first, that the medical profession acts in no exceptional manner when it has to deal with law, inasmuch as its whole business is the discovery and application of the laws of Nature. 2nd. That when its medical and legal professions come in contact, it is not because either of them disputes the existence of, or necessity for obedience to, the laws which it is the business

of the other to expound ; but because misapprehension has arisen with regard to the appreciation of the one, or the application of the other, in a particular case. 3rd. That differences of opinion exist in all departments of thought when regard is paid to any complex phenomena; and, that these differences are not greater in scientific than in unscientific matters, and not more pronounced in medico-legal investigation than in any other form of scientific inquiry. 4th. That scientific testimony must consist of both facts and opinions, and that the difference between these two elements of evidence is not so great as is sometimes imagined, inasmuch as the statement of scientific fact involves to some extent the element of opinion. 5th. That the conditions which give value to the statement of facts are threefold; (a) that they be observed, and in order that this may be the case, that they be "looked for;" (b) that they be well observed; and, hence, that the examiner be both informed and skilled; (c) that they be truthfully and exactly represented; and, hence, that the witness be honest. 6th. That "expert" evidence is, by these conditions, rendered necessary in regard of facts; but, that the difficulties thrown in the way of the medical expert are as great as they can be, owing to the nature of the case, the circumstances in which the medical examiner is placed, and the necessary conditions of human thought.

There is no human faculty more difficult to exercise fairly than the judicial, and this is so even when the circumstances which call for its operation are the most conducive to its healthy development. There is no faculty which is, perhaps, more easily abused when the conditions are unfavourable; and the circumstances in which a medical witness is sometimes placed are as unfavourable as can be conceived. He is called in to see a patient, or a party, who, if not treated unfairly at all, believes or represents such to be the case; usually many conferences, and much legal correspondence have already taken place; the individual or individuals supposed to be aggrieved throw what is said on the opposite side, and often carefully conceal much of it; they know their own weak points, and hide them; they are aware of their strong points, and bring them prominently forward, or dexterously and simply take pains that they shall be seen; they are primed to the full with all that tells on their own conclusion, and ignore carefully all that might count against it.

His tale is an *ex parte* one of injury done or about to be inflicted; the objections raised by the other side—viz., those which are communicated, are often tortured and exaggerated; this story is, or may be, consistent with itself, and with the facts that can be observed; and if, in its telling, it is not over-done, and the other doctors appealed to with apparent frankness, and a few complimentary speeches as to his knowledge and candour, and with the utterance of an earnest wish that he would "simply express his opinion, whatever it may be," he may, in rare instances, take the opposite side, in still rarer will he, or can he, hold the balance evenly, while in many—with the most upright of intentions—he takes some bias not necessarily in opinion, but in his observation of the facts. He sees the case, not of choice but of necessity, from a particular point of view, and from that point he may fail to see all that it contains, all that bears upon it. There is no dishonesty in this, although there may be weakness; something might be done to alter the circumstances, as I hope to show hereafter, but under the circumstances, which the physician cannot alter, he is placed at a disadvantage.

Let it be remembered that truth, or at all events all the truth, is not always with either the one or the other side, that indeed it not unfrequently lies somewhere between the two—a little on this side or that of the line which is about to be drawn—and that sometimes the line is one which, on purely scientific grounds, the medical witness would not be disposed to draw; further, it must be remembered that even an *ex parte* statement may be correct, and may be legitimate up to the line that has to be drawn; that with all the apparent strong conviction there may be an equally apparent integrity of purpose, and that this may be entered into and found in accordance with all the facts

then to be observed, and under such circumstances it is still more difficult, nay, it may be impossible, for the physician to act judicially upon the whole case. Some facts, or reputed facts, are beyond his immediate cognizance. The account given of them may tally with what he sees, and thus they influence his observation upon the case. Under circumstances of this kind I have described, and they are by no means rare, the medical examiner has great difficulty to contend with. He must start from some ground, and that ground is given him. Some people are so contradictory in their temperament that they always fly to the opposite extreme of that which is suggested to them, and in doing so usually make more blunders than it would take another life-time to set right again; but the majority, by a law of their nature, start from the point at which they find themselves, and, if honest in their purpose, come to the truth. The physician may be so directed as to omit a search for facts, which, with another direction, he might have looked for; but his conduct may be as honest as his wish, and his omission was simply due to some portion of the case having been kept out of sight.

Honesty of observation is but gained, I think, by placing oneself in opposition to one's own pet theories, and endeavouring to ascertain all the facts which might militate against them. It is hard to do this fairly, but yet it may be done; when done, however, it will not prevent the evil then alluded to, the necessary lies as to facts in a doubtful case. Few men could so play at chess, the right hand against the left, as to ensure a long succession of drawn games; few can hold the balance so fairly as to be influenced only for the right by everything they hear and see, &c., but all can exercise their faculties to the highest point of honour, and this I believe in the vast majority, even of discordant cases, has been done by the members of our noble Profession. The discrepancies that have arisen have not, with infinite rarity, been done to any dishonesty of purpose, but have occurred simply from a want of proper knowledge of scientific facts, and from the absence of knowledge of the actual facts of the case under consideration.

7th. That the introduction of "opinion" into medical evidence is necessary because the questions raised can only be determined by regard to either the past or the future—*i.e.*, to either the *cause* of symptoms, or their probable *result*. 8th. That in the search after cause, and in the attempt to estimate effects, the examiner and the witness pass into a region of thought altogether different from that which they occupy when observing and detailing facts. 9th. That the difficulties in the exercise of such mental processes are, under all circumstances, weighty, and that they are sometimes insurmountable; but that, 10th, in certain cases which form the topics of medico-legal investigation they are as great as it is possible for them to be, and are such as cannot be overcome. This is so, because medical science, in its present state, is not in a position to determine the precise state of relation or right of sundry concurrent causes; it is unable to foretell with certainty the result of many injuries or diseases, the present condition of which it may appreciate; and yet, further, with regard to a considerable number, its power of prediction is reduced to a simple guess. The statement of a statistical result may be true, and of real value for the appreciation of the fraction of a large group of cases, but its most minute expression may be untrue, and worse than valueless to the individual.

---

DR. RICHARDSON announces a course of lectures on Experimental and Practical Medicine, to be delivered on the first Tuesday of every month except July, August, and September. The subjects of the lecture to be given on the 2nd April are, a new Styptic and Adhesive Fluid, "Styptic Colloid," and Healing by the First Intention.

A CORRESPONDENT of the new paper, *The Day*, suggests that Fenianism, with its various "circles" and its "head centre" is a sort of political ringworm, which it may be found very difficult, indeed, to cure. The idea is not a nice one, but it may be true.

CLINICAL LECTURES  
DELIVERED IN  
STEEVENS' HOSPITAL,  
TOGETHER WITH  
OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,  
PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,  
PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

OBSERVATIONS ON THE HEMORRHAGES.

(Continued from page 269.)

THE hemorrhages of incoming and outgoing fever are as distinct, the one from the other, both theoretically and therapeutically, as any two symptoms can well be.

Here, however, we must carefully avoid confusion; we must endeavour (the diagnosis is not always an easy one) to distinguish between the bleeding of exhalation and that of ulceration. In many fevers, intestinal ulceration with hemorrhage marks their advanced period.

In all the hemorrhages this is a most important point of distinction; in none more than in the uterine; in truth, it is the pivot on which the treatment mainly turns. The same remark applies to epistaxis.

A gentleman, aged 56 or 57, who had just returned from the Continent, told me that, for the previous five weeks, he had been harassed with repeated attacks of epistaxis; not a day passed without a frequent dropping of blood from the nose; he was afraid to drive out, to take part in public meetings; all his pleasures and pursuits were interfered with and spoiled; often on awaking he found his pillow stained with blood; he never lost much at a time, and was rather annoyed and distressed than materially debilitated. He had never till then bled from the nose, nor had he ever before been subject to any form or variety of hemorrhage. This fact led to a minute local examination, and then it was that the true source of the bleeding was discovered. A vascular spot of ulceration, difficult at first to see, became apparent. A few applications of the actual cautery completely cured the epistaxis. This gentleman had been, for five weeks previously, subjected to cuppings at the back of the neck, astringents, applications of ice, saline aperients, and all sorts of dietetic restrictions. The cause of the oversight was, that he had never felt nor complained of any local pain or uneasiness.

I have met with several cases, in many points identical with that now detailed. Nay, I have seen cases of nasal polypi and consequent epistaxis treated constitutionally, the local source of the bleeding having been left wholly unexplored. Such an oversight redounds not much to the glory of medical sagacity. In epistaxis, as well as in all other hemorrhages, a most searching analysis, local and constitutional, is required, to prevent the grave diagnostic error of confounding a hemorrhage which results from local disease, ulcer, or injury, with that which springs from a constitutional cause. Obvious as all this is, it is surprising how often such an oversight is committed.

What advantage can possibly arise from treatment exclusively constitutional, in cases of uterine ulcerations or polypi, or retained placenta, or other purely local sources of hemorrhage? When, however, as it often happens, ulcerations are co-existent with the hemorrhagic diathesis, the treatment, both local and constitutional, is imperatively indicated. So it is with epistaxis: if locally caused it will not be constitutionally cured.

One of the most frightful cases of epistaxis I ever witnessed occurred in a case of organic disease of the heart. The gentleman was between thirty and forty years of age, upwards of six feet high, with very expanded chest, and great muscular development. He was born in a tropical clime, and ardent in all his passions as the sun under whose burning rays he was nurtured. Hypertrophy of the heart, with disease of all its valves, to an extent such as I had

never before nor since witnessed, was the fearful disease under which he laboured. In no instance have I heard the cardiac impulse at so great a distance from the chest. In no instance have I seen so extensive an undulation of the parietes of the left thorax and epigastrium, and elevation and sinking of the clothes that lay on the chest. In no instance has the stethoscope been impinged against my ear with so much force. I was urgently requested to go without delay to see this gentleman; I found him bleeding in torrents from both nostrils; he had been thus bleeding for hours before my visit; the quantity of blood extravasated was enormous. Before I left the house the hemorrhage had abated. An intelligent medical pupil, a friend of his own, remained with him. The bleeding returned with so much violence that his friend, apprehensive of fatal consequences, was induced to plug both nostrils, from the posterior nares, with plugs well steeped in oil of turpentine; after some time heat and tingling were produced, soon, burning pain, which increased so much that it became necessary to remove the plugs; even after their removal the pain increased so as to be absolutely maddening. He lived for several weeks, but never afterwards bled from the nose. Probably, as a consequence of the action of the turpentine, the membrane remained permanently thickened, so as to render future bleeding improbable.

Possibly, in some persons of hemorrhagic diathesis, a state of the membrane, analogous to that produced here by the application of turpentine, may naturally exist and impede the flow, which would otherwise take place from the mucous surface of the nares.

I have repeatedly heard some, who were harassed with deep flushings, headaches, facial eruptions, heat of head and face, say, they would give the world to bleed from the nose, and they had all the sensations, such as heat, tingling, turgescence of vessels, throbbing, and redness, which very often precede and forewarn a flow of blood from the nares.

In these cases I have known much mitigation of symptoms to ensue after the repeated application of leeches to the septum. This method of leeching, some are too irritable to endure. In a very few it has produced violent sneezing. As a general rule, it is, in suitable cases, an excellent method of abstracting blood. A useful hint may be derived from the action of the turpentine; although, in this case, it was too violently applied. This gentleman died from the sudden rupture of one of the tendinous chords of the mitral valve. The sound of the rupture was audible to himself. It occurred in a moment of anger and indignation; he had been most unkindly treated by one who should have been the last so to treat him. From the moment of the rupture he was in agonies; they endured for six hours, when he expired. The heart was preserved in the museum of the Park-street School of Medicine, and was one of the most valuable preparations amongst those of that excellent pathological collection. This is one amongst numerous instances of a temporary epistaxis caused by an organic disease.

Disease of the brain is not unfrequently accompanied by this symptom. In the month of December last I was sent for in haste to see a lady in her fifty-eight year, who suddenly, and without any premonition, was, whilst sitting at dinner, seized with severe epistaxis; this was her first, and, up to the present time, her last hemorrhagic seizure. It was preceded by obscure signs of cerebral disease. Since the attack of epistaxis the evidences of gradually increasing organic disease of the brain are unequivocal.

The following case of a single occurrence of epistaxis may (as illustrative of the subject) be worth placing on record: Mr. S., between fifty-five and fifty-eight years of age, of low stature, large head, short neck, very large chest and trunk, with comparatively diminutive extremities, has been for years subject to that chronic form of bronchitis and habitual catarrh, which abates during the summer, but never wholly departs, accompanied by expectoration, and an habitually restricted and wheezing respiration. He retired to rest in the winter season with a more than usual

amount of thoracic oppression. He slept heavily, but unrefreshingly. Early in the morning he awoke, with intense headach and throbbing of the vessels of the head, heat, and flushing. Soon blood began to flow from both nares, and that to a very considerable amount. Finding that from the natural blood-flow no prompt relief was derived, and that the head symptoms were becoming even more urgent, I determined to open a vein in the arm. He was raised in bed: a full stream of blood issued from the orifice. I remained with him, and allowed the blood to flow till the force of the cardiac and arterial impulses was subdued. He became slightly faintish; the epistaxis ceased, and every urgent symptom was speedily relieved.

Before taking a final leave of that part of the subject which relates to the occasional and temporary conditions of the vascular system, which give rise to epistaxis, a few words may be devoted to the consideration of one of its very frequent varieties, which, conjoined with other hemorrhages, holds a prominent position amongst the symptoms indicative of a remarkable change in the texture of the blood, a change of which sea-scurvy and purpura are the clearest types.

Sea-scurvy is primarily the result of a nutriment either deficient in quantity, or injurious in quality, generally of both. This altered condition of the blood, and its consequence, hemorrhage, may arise from purely dietetic causes. It is a remarkable fact, that this change in the structure of the blood is accompanied by a corresponding change in that of the solids. The gums become spongy and bleeding. Ulcers are readily produced, and refuse to heal. Old and perhaps long-healed sores re-ulcerate; previously united fractures disunite; the muscles are enfeebled; and the brain and nerves, not deriving from the blood a full organic supply, are prostrated in function; the spirits are miserably depressed; the will loses its influence, and death is preferred to intellectual or muscular labour; also, blood oozes from many surfaces, frequently from the nares, and the effluvia emanating from the breath and person is often highly fetid.

In contemplating the causes of sea-scurvy, it is necessary to take into account the tedium and monotony of a seafaring life. These, I am informed by persons who have spent weeks and months without ever seeing land, are most irksome and depressing. Hence, the sudden and extraordinary restorative effects of exhilaration of the spirits. The sight of land, the prospect of plentiful supplies of wholesome and vegetable food, by raising the spirits, by improving the nervous and respiratory functions, go far in promoting recovery, even before these supplies come into operation. Hence, too, the important rule, that it is the duty of those in command in long voyages, to provide for the ship's crew not only ample supplies of wholesome food, but also such varied amusements as shall render the time spent on the ocean less wearisome, tedious, and monotonous.

During the late famine, many patients, affected with purpura, presenting all the signs of sea-scurvy, were admitted into the wards of Steevens' hospital. They did not belong to the class of the destitute.

I learned that their whole sustenance was limited to a very stinted allowance of wheaten bread. Weak tea they took in large quantities. No butter, scarcely any milk, and very little sugar. Some partook largely of weak and adulterated coffee. The sensation of want and emptiness from insufficiency of solid food, was in a measure counteracted by drinking in large quantities these weak infusions. Thus an insufficient and watery diet, too scantily supplying the staminal principles necessary to effect a perfect sanguification, is capable of giving rise to all the distressing symptoms by which purpura is characterized, and amongst them to many forms of hemorrhage, including epistaxis. In these cases we may aver, that there are simultaneously softening of the blood and softening of the solids. Such cases of purpura, if not too far advanced, are perfectly curable. The treatment is mainly dietetic. The vegetable acids materially assist in restoring a healthy sanguification. In the hospital we have given, with good effect, to these

patients cold infusion of Peruvian bark, mixed in equal proportion with lime-juice, having added, in many cases, the citrate of quina, and as much substantial food as an enfeebled stomach could with facility digest. A few of these cases which resisted treatment evinced before death signs of dropsical effusions, as if to show how an abnormal condition of blood leads first to effusions of coloured blood, then to effusions of uncoloured blood, often to both combinedly, and also to prove how intimately connected the one with the other are the passive hemorrhages and dropsical effusions.

The epidemic and fatal dysentery, or, as it has not inaptly been termed, bloody flux, which has lately and during former famines swept hundreds away, is mainly referable to deterioration of the circulating fluid, caused by insufficient and unsuitable nutriment. Its origin is dietetic and the most efficient item in the treatment is likewise dietetic.

(To be continued.)

## Hospital Reports.

### LONDON HOSPITAL.

TABLE OF ACCIDENTS ADMITTED INTO THE LONDON HOSPITAL DURING THE WEEKS JANUARY 22-29, FEBRUARY 12-19, AND FROM MARCH 5-12.

	Jan. 22-29.	Feb. 12-19.	March 5-12,
Fract. tibia and fibula . . . . .	8	2	1
Compound " " . . . . .	2		1
Fract. fibula . . . . .	1	1	2
" femur . . . . .	1 shaft	2 neck	2 neck.
Potts' fracture . . . . .	0	0	1
Compd. fracture of skull . . . . .	2 1 trephined	0	0
Fract. ribs . . . . .	2	2	4
Retention . . . . .		1	1
Burns and scalds . . . . .	4	2	0
Local inflammations after injury . . . . .	10	1	4
Lacerations . . . . .	9	8	9
Incised throat . . . . .	0	0	1
Punct. wound of abdomen . . . . .	0	1	1
Orchitis . . . . .		1	1
Contusions . . . . .		7	3
Admitted as out-patients	365	283	238

Of the fractures of tibia and fibula admitted during the first week, four of the simple, and one of the compound ones were owing to the slippery state of the streets in consequence of the frozen rain on January 22nd. The total number of casualties owing to this cause was 82.

Of the cases of fractured ribs admitted in the last week, one patient, a boy of 17, had fallen from a cart and had fractured several ribs on the left side; was found to have also a fracture of the pelvis; he had hæmaturia for the first day after admission, and the anterior part of the crest of the ilium on left side was moveable, the measurement from the anterior superior spine to the knee being half an inch less on this side. He has had an attack of double pneumonia affecting all the posterior part of both lungs, from which he is recovering satisfactorily.

One case of comminuted fracture of the clavicle was admitted, as being caused by direct violence, there was a possibility of damage to parts beneath, and the inner fragment projected so as almost to come through the skin. The deformity could only be reduced when the patient lay on his back; the arm was bound to the side with a pad in the axilla.

There were also a few other cases of smashed fingers and toes admitted, but nothing of any general interest. One case of compound comminuted depressed fracture of skull has already been published; the other fracture of the skull was simply a fissure, and produced no symptoms whatever.

One of the cases taken in as a contusion was of some interest. The patient came first on Sunday evening, Feb. 19th, stating that she had slipped down some steps and

struck her back on the day previous. On examining it there was found a red circular patch, having a hard brawny feel, and softening in the centre, and looked exactly like a patch of inflammatory effusion passing into suppuration. As the woman's statement, however, was in favour of its being effused blood she was kept at rest with a warm fomentation applied; but in two days it burst and discharged about a pint of pus, and quickly healed.

### ST. GEORGE'S HOSPITAL.

#### OPERATION FOR VARICOSE VEINS.

Under the care of Mr. HENRY LEE.

LUCY W., *æt.* 32, was operated upon on Feb. 28th for varicose veins, which were greatly enlarged both above and below the knee. The interest of the case consisted in the patient having been operated upon two years ago in another hospital without being in any material degree relieved. Mr. Henry Lee remarked that there were two cases now in the hospital in which operations had been performed upon varicose veins, and in which the patients had apparently derived very little benefit from the proceeding. Mr. Lee was naturally anxious to know what operation had been performed in those cases, and upon inquiry it was found that in the first instance the enlarged vein had been compressed between two needles, and in the present case a needle had been placed under the vein at five different points, and a piece of bougie in each situation pressed firmly down upon the vein by means of "8" ligatures. These needles were allowed to remain in three weeks, but when the patient walked about afterwards the inconvenience was found to be as great as before the operation. Mr. Lee believed that both these modes of operating were based upon a false pathological theory, and one which was, nevertheless, to be found in some of the most recent works on surgery. It was supposed if the opposed surfaces of an artery or of a vein were pressed together for a certain time that they would adhere by means of effused lymph, as two opposed serous membranes would do.

Now, theoretically, according to the best authenticated and most recent experiments, this ought not to happen; and, practically, it was found, as in the cases alluded to, not to occur. There was here a point of contact between science and art where those both spoke the same language.

In order to produce a permanent obliteration of a vein its coats, Mr. Lee believed, must be divided, and then a vascular union would take place from opposite sides, and this was the operation which he always performed. In the case of Lucy W., this operation was now performed both above and below the knee on the internal suphena vein, the divided portions of vein being isolated from the rest of the circulation by accupressure needles. Mr. Lee remarked that if gentlemen would watch the case they would have an opportunity of seeing the difference, as uttered by nature, between the results of simply compressing a vein and effects of dividing it in the manner which he had done.

## Reviews.

### THE ARREST AND PREVENTION OF CHOLERA.

By A. E. SANSON, M.B.Lond. London: John Churchill and Sons.

DR. SANSON has succeeded in clearly expressing his views on the nature of cholera in a work of very moderate compass. This very condensation, however, renders his contribution all the more valuable; for, too often, the really *original matter* contained in larger books is to the reader as scarce as are ears of corn to the gleaner in a well garnered field.

Dr. Sanson considers that cholera is caused by living germs, and that these act in a two-fold manner, primarily by irritation of the mucous lining of the alimentary canal; and, secondly, by causing irritation of the sympathetic system.

The treatment advised is, of course, based on the pathology. It must, in the main, be an "eliminative," or what the author considers even a better plan, "to kill the germs" by certain agents, especially sulphate of soda. After the attempt to kill and expel the germs, should the purging still persist, Dr. Sanson considers it should be checked, as it is an evidence of the remaining germ transmuted to an irritant poison on the great sympathetic nerve.

Now, although it is quite possible that cholera may be caused by the organised living germs described by Dr. Sanson, we must remember that such view is at present but an hypothesis demanding clearer proof than we at present possess. It may be forthcoming. Awaiting it, however, we must not be misled into the possible error (in encouraging an eliminative process) of augmenting the dangers of the disease. The chapter on the Pathology of the Sympathetic Nerve is very interesting and clear. The lecture on Disinfecting and Decomposing Agents is most valuable. In short, we commend this little work to all interested in the matter of epidemic diseases.

**HISTORICAL SKETCH OF THE EDINBURGH ANATOMICAL SCHOOL.** By JOHN STRUTHERS, M.D., &c. Professor of Anatomy in the University of Aberdeen. Edinburgh. 8vo. 1867.

To such of our readers as feel an interest in the biographical and antiquarian literature of our profession, few books will prove more acceptable than this very readable work of Dr. Struthers, who has herein shown himself well qualified for the task which he has undertaken. If we mistake not, the substance of this volume appeared first in the pages of our valued contemporary, the *Edinburgh Medical Journal*. We have here sketches of the three Monro's, John, and Sir Charles, Bell; Barclay, Gordon, Innes, Fyfe, Alexander Walker, Craigie, Cullen, and Knox; and a perusal of them, and of the other matters detailed by Dr. Struthers, cannot fail to interest even the non-medical literati.

**EDINBURGH MEDICAL JOURNAL.** March. 1867.

THE current number of our contemporary contains five original communications by Drs. Patrick Heron Watson, William Jeffrey, Alexander Milne, David Skae, and William M. Dobie, respectively; several good reviews, and an interesting amount of miscellaneous matter, including a very readable obituary of that lamented physician, the late Dr. Scoresby Jackson.

**ON DISEASES OF THE SKIN,** including the Exanthemata. By FERDINAND HEBRA, M.D., &c. Vol. I. Translated and edited [for the new Sydenham Society], by C. HILTON FAGGE, M.D., &c. 8vo. 1866.

THE professional reputation of Professor Hebra is so well known to every medical man of education in these countries, that we not only have no occasion to criticise the excellence of this or any other work of his, but his very name is a sure guarantee to our readers that his book must be a good one; and so it is. We feel that the work of a reviewer is at times difficult enough in endeavouring to pass an opinion on some of the works published by the new Sydenham Society, and for this reason, the books are in general works of repute, and it is the translation and editing which in fairness ought to be reviewed and not the original work. Professor Hebra's work differs, however, from many of these books just adverted to in two important particulars. The author has himself re-written for this edition Chapters V. and VI., on the affections of the glandular organs of the skin, and the greater part of Chapter XV. of which herpes is the subject; and he has also read over every sheet of the translation, and (observes the translator) "every passage in which I felt any doubt as to the faithfulness of the translation, or as to the sense of the original, was underlined by me, and has been accepted by him, or corrected so as to convey the right meaning."

The editor mentions a fact which he says "will be deemed of interest in reference to the writings of Willan." Professor Hebra quotes from a German translation of a work of Willan published at Breslau in 1799:—

"Now (continues Dr. Fagge) the earliest treatise on diseases of the skin by the great English dermatologist, contained in any of the large medical libraries in London, is the quarto dated 1808; and the only reference I have been able to find to any previous work of his on this subject is the statement that the Fothergillian gold medal had been awarded to him in the year

1790, by the Medical Society of London, for a classification of Cutaneous Affections. It would, therefore, seem that a publication, which was at the time deemed worthy of translation into German, has fallen into complete oblivion, having, no doubt, been eclipsed by the well-known later writings of its author."

The note on page 15, to which Dr. Fagge refers, is one from the editor, who comments on Hebra's mention of Willan's "Phlyctis" by saying: "In the English work 'On Cutaneous Diseases' (Vol. I., Introduction, p. 13), Willan mentions the Phlyzium, the Psyracium, the Achor, and the Cerion or Favus, but not the Phlyctis."

Now, we have the best reason for asserting that the editor is incorrect in the above deduction. The usual London logic, that if a thing be not in the great city it cannot be found anywhere, may be very good in its place, but certainly not here. The book which, because it cannot be found in the large medical libraries in London, "has fallen into complete oblivion," can be easily read in the library of the King and Queen's College of Physicians in Dublin. It was published in London in 1798, and establishes the fact that Hebra correctly connects the Phlyctis with Willan's name. The old book in question refers to the award of the Fothergillian gold medal to its writer; and is doubtless the volume which was translated into German, and published at Breslau in 1799.

This volume before us runs over 396 8vo pages, and comprises XV. Chapters. It is only the first part of the complete work; the remainder is promised before the end of the present year. In this short notice it would be unfair to the author and to the editor to attempt anything like a critical review of the entire volume; we may, however, remark on the translation, that it is to a large extent free from those intolerable Germanisms which make books so treated as this has been, almost intolerable to the patience of the mere English reader. It may be read with comfort, and even with interest, by those who feel little interest in the subject matter discussed in it; while, to the reader who may have a special liking for the subject of dermatology, it will not fail to bring very much new information of the most useful kind. The table of contents will, however, stagger the English reader a little. He will find some awful jaw-breakers, in the form of words having a terrible and unusual sound; but he will soon discover that they are grand names for very plain things. He will have to become familiar with "active hyperæmia," "symptomatic passive hyperæmia," "bromidrosis," "hyperidrosis," "anidrosis," "galactidrosis," "chronic exudative dermatoses," and many other words of this sort; but these once mastered, his task will be an easy one. Chapter I. treats of the General Pathology and Symptomatology of Cutaneous Diseases under these three heads:—Primary symptoms or forms of efflorescence; secondary symptoms; and, on the distribution of eruptions over the skin. Chapter II. treats of diagnosis, etiology, treatment, and classification; and on p. 48 the reader finds the classification which dermatologists have long known as Hebra's, and which appeared more than a year ago in an English dress on p. 14 of Dr. Belcher's edition of Neligan "On Diseases of the Skin." Chapter III. treats of the first of Hebra's classes—"hyperæmia cutanæa"—diseases of the skin, which arise from the presence of an excess of blood in the capillary vessels of the cutis; Chapter IV. treats of the second class—"anæmia cutanæa"; and Chapter V. begins the discussion of class three—"anomalie secretionis glandularum cutanearum:" diseases due to perverted states of the secretions of the cutaneous glands.

That portion of the work which begins on p. 74 under the heading "Affections produced by morbid states of the materia perspiration," is especially worth reading, for it has been long identified with the name of Hebra, and no more full descriptions or discussions on such diseases or conditions, as bromidrosis, hyperidrosis, and anidrosis can be found, than we have read in this volume.

As regards the treatment of persons suffering from fetid perspiration of the feet, Professor Hebra advises, in the first place, the removal of the shoes and stockings, and all other matters which may have become impregnated with the fetor. When this has been accomplished, the procedure is as follows (we quote from p. 89):—

"A certain quantity of the simple diachylon plaister (emp. plumbi emp. liohargyri) is to be melted over a gentle fire, and an equal weight of linseed oil is then to be incorporated with it, the product being stirred till a homogeneous mass is produced, sufficiently adhesive not to crumble readily to pieces. This is then to be spread over a piece of linen, measuring about a square foot. The foot of the patient having been first well

washed, and thoroughly dried, is now to be rapped in the dressing thus prepared. Pledgets of lint, on which the same ointment has been spread, are also to be introduced into the space between each pair of toes, to prevent their touching one another, and care must be taken that the foot is completely covered, and that the dressing is accurately in contact with the skin. When this has been done, an ordinary sock or stocking may be put on the foot, and out-side this a new shoe, which must be light, and should not cover the dorsum of the foot. After twelve hours the dressing is to be removed, the foot is then not to be washed, but must be rubbed with a dry cloth, or some one of the above named powders ["starch, lycopodium, powdered asbestos, almond bran (mandelkleie), or even common flour," p. 89], may be applied to it. The dressing is then to be removed in the same way as before, and its application is afterwards to be repeated twice a-day. This procedure must be continued for from eight to twelve days, according to the severity of the case. During this time, however, the patient need not keep his room, but may go on with his business as usual. At the end of this period the dressing and pledgets are to be removed, the foot is to be again rubbed with some pulverulent substance, and the patient may then be allowed to wear his ordinary shoes and stockings." He then specifies other particulars of minor importance, remarking that in some "quite exceptional cases" the whole procedure must be gone through a second time; and he adds, "but this will certainly, and without exception, bring about a cure." Professor Hebra has practised this method "for more than twenty years, and in many hundred cases."

Chapter VIII. contains one of the most valuable treatises in existence on morbilli or measles. This was originally written by the late Dr. Franz Mayr, clinical professor of the diseases of children in the St. Anna Hospital at Vienna; and it is now revised, and in fact re-written, by Professor Hebra. Chapter IX., incorrectly printed at the head of the chapter (see p. 188) as Chapter VIII., which was also written by Mayr, and revised by Hebra, is an equally valuable treatise on scarlatina; and perhaps not the least valuable part of it is the diagnostic table between measles and scarlatina, which commences on p. 220, and specifies the diagnosis between these two affections, A in the stadium prodromorum; B in the stadium eruptionis; C in the stadium floritionis; and D in the stadium desquamationis. Chapter X. is an exhaustive tractate on small-pox; Chapter XI. on cow-pox; and Chapter XII. comprises erythema, pellagra (by Mayr); acro-dynia, roseola, and urticaria. Chapter XIII. is "on the dermatitides proper." Chapter XIV., containing the subject of Chapter XIII., treats of erysipelas, "dermatitis plegmonosa," or plegmonous inflammation of the skin; glanders; the pustular affection produced by the cadaveric poison; and pustula maligna. Chapter XV. deals with the important subject, herpes, a word of which Hebra accepts the definition of Willan; also with miliaria, and with acute pemphigus. While the portion of this chapter devoted to herpes is quite exhaustive, that allotted to acute pemphigus is, in our opinion, very meagre, especially when compared with the others already mentioned.

For the reasons already stated, we do not propose to enter into any criticism of this most able book. To ordinary practitioners there will always be too much of the foreign spirit and element found in and about it, to render it a hand-book on diseases of the skin; but to such as feel a peculiar interest in the subject with which it deals we cannot commend it too highly; not by any means, however, being understood to approve of all opinions expressed in it, even by such an authority as Hebra. As to the "get up" of the work, if all copies are such as that sent to us, it may be well to say another word to the reader. By some strange mistake pp. 353-384, both inclusive, are bound in between pp. 32 and 33, while there is a corresponding gap at the end, p. 335 following immediately after p. 352. This should be remedied in the unbound copies; and such as have copies like ours should make the necessary correction in order to avoid confusion in reading and reference.

A MANUAL OF THE PRINCIPLES OF SURGERY, BASED ON PATHOLOGY, FOR STUDENTS. By WILLIAM CANNIFF, M.D., New York, M.R.C.S.E., late Professor of General Pathology and the Principles and Practice of Surgery in the University of Toronto, &c. Pp. 402. Philadelphia: Lindsay and Blakiston. 1866.

DR. CANNIFF, who dates his preface from Belleville, in West Canada, and who appears to have enjoyed great opportunity, for obtaining surgical experience, both in civil and military practice, states that he originally prepared the present volume

as a hand-book for the use of students while he was engaged in lecturing on the Principles and Practice of Surgery, but that since he withdrew from that duty he has extended the limits of the work, so as to make it more generally useful. The ground-work is derived from his own course of lectures, and these again are based upon the best European authorities on surgical pathology. The manual is arranged into five divisions, the first of which is devoted to Inflammation and the Diseases arising out of Inflammation; the second to the Healing Process and the Diseases of the Healing Process, as Ulcers; the third to External Injuries, as Contusions and Wounds; the fourth to Diseases of certain Tissues, Bones, Joints, Arteries, and Veins; and the fifth to Morbid Growths.

In the pathological views expressed, as well as in the recommendation of treatment, Dr. Canniff has taken as his guides the leading authorities of the present day, and his therapeutical precepts are cautiously deduced from a well-balanced consideration of modern doctrines, verified by his own experience. The antiphlogistic treatment of inflammation, for instance, especially by general bleeding and the free administration of mercurials, is called into question, and the preference is given to the use of opium, the employment of stimulants, and the administration of the *veratrum viride*. This last-named drug, the potency of which is unquestionable, has, as is well known, a high reputation with transatlantic practitioners, and it is now introduced into the forthcoming British Pharmacopœia. Dr. Canniff writes of it in eulogistic terms as a remedy for inflammation; but we cannot say that his illustrations of its peculiar efficacy in inflammation of the lung, are, to our mind, perfectly convincing. He gives two cases of pneumonia, both caused by gunshot injuries to the chest, in which he conceives that the administration of the *veratrum viride* was a powerful curative agent; but when we recollect the numerous kinds of treatment recommended for pneumonia, all of which are said to have been successful, and when we recollect, moreover, that pneumonia will sometimes be cured with little or no treatment by drugs, we are inclined to be sceptical as to the merits of the green hellebore, which, however, deserves a trial. In the treatment of syphilis, mercury is considered by Dr. Canniff to be efficacious, but to be more dangerous than iodide of potassium, and he recommends the latter to be first tried before recourse is had to the former. The work of Dr. Canniff is altogether creditable as a Manual of the Principles of Surgery.

### INSANITY IN THE PROBATE AND DIVORCE COURT.

AMONG the most important social duties which a man or woman may be called upon to perform during the journey of life, are the contraction of a marriage and the making of a will. The former step, unwisely, even if not unlawfully, taken, too often leads to misery and useless repentance on the part of those who enter into the contract; the latter, while it confers no advantage on the testator or testatrix, too frequently leaves upon survivors a sting which years are powerless to remove; it alienates property to which relatives have a moral if not a legal right, or it confers upon strangers what is withheld from lineal or collateral descendants. But whatever may be the miseries resulting from ill-assorted marriages,

the parties who contract them must bear the punishment, provided that both the man and the woman in each case are competent to execute any lawful act; and whatever may be the hardship endured by wives, or sisters, or children, deprived by the last will of their husbands, their brothers, or their parents, of what they may regard as their rightful expectations, they must anticipate no redress, and unless they can prove testamentary incapacity, must bear their sorrows and their disappointments in silence. But the law very properly insists that either in the contraction of a marriage, or in the execution of a will, the principal agents should be of competent intellectual capacity to understand what they are doing; and the records of the Probate Court abound with instances in which the question of testamentary capacity or incapacity has given rise to lengthy and expensive litigation. It is by no means so frequent that the validity of a marriage is contested on this ground; but a recent case in the Divorce Court affords an instance in point, and the observations we have just made are illustrated by the two decisions given by the Judge Ordinary (Sir JAMES WILDE) on the cases *Young v. Dendy*, and *Hancock v. Peaty*, last week.

In the former case, the will of a Miss DENDY was opposed on the ground of the insanity of the testatrix, and her brother was the defendant in the suit. The decision of the jury was in favour of the will, thus affirming that the lady was of sound testamentary capacity, and having the effect of alienating a very considerable property from the lady's own family. It may be mentioned that the evidence of insanity, though it was insufficient to convince the jury, was very strong indeed, and in fact the only question seemed to be, not whether the lady was insane or not, but whether she was insane at the time of making the will which was the subject of dispute. But the evidence in favour of the will went to show that she was of sound mind up to the time of her death.

The brother, however, being dissatisfied with the verdict, and additional evidence in favour of the insanity of his sister having been obtained since the trial, an application was made to the Judge Ordinary for a new trial, which has been granted. Sir JAMES WILDE, in giving judgment, evidently thought that those who propounded the will had endeavoured to prove too much, for after the death of the testatrix a number of papers had been discovered, which manifested the existence of delusions and trains of thought inconsistent with a healthy mind. The Judge seemed to think, therefore, that the insanity was clearly proved, and the issue to be raised at the next trial will be as to the period when the insane trains of thought were developed, and whether they existed at the time when the disputed will was executed.

In the other case in which judgment was given on

the same day by the same Judge—namely, the case *Hancock v. Peaty*, the very unusual question was raised as to the validity of a marriage contracted when one of the contracting parties was alleged to be insane. This case, it will be recollected, was tried without a jury, by which course, expensive as the suit has no doubt been to all the parties, much time, trouble, and expense have been saved, and a very able, learned, and satisfactory judgment has been obtained. The whole case is a very painful one, and it is extremely difficult to understand why it was brought into court at all, as none of the parties had any pecuniary interests at stake whichever way the matter was decided, and all of them must be involved in very considerable costs. It should also be mentioned that the husband, so far from being amenable to blame in his part of the transaction, is entitled to the very highest credit for his consistent kindness to the unfortunate lady whom he has made his wife, and whose insanity, at certain periods of her life at least, appears, by the evidence, to have been very strongly attested to. Indeed, she was placed in a lunatic asylum at the express instance of her husband.

The judgment of Sir JAMES WILDE in this case is a model of judicial impartiality and fairness, and is characterized, moreover, by a spirit of kindness and sympathy for all the parties in the unfortunate suit. But his opinion is very strong indeed that at the period when the marriage was contracted, nay, on the very day when the ceremony was performed, the lady was not in such a state of mind as to enable her to enter legally into so solemn an engagement, and he therefore pronounces, though with an expression of regret, that the lady's relatives have established their position as to her incapacity to contract marriage. The Judge takes pains to review all the evidence on which his judgment is founded, and he specifies so many particulars as to eccentricity of conduct, that very few, we apprehend, will be found to question the conclusion at which he has arrived. But he intimates, that as the lady's husband asserts that she has now recovered, and is in a sound state of mind, there will be no decree of nullity of marriage until that question is settled, and if, upon investigation, he desires to try the point, the Divorce Court will give him every facility for the purpose. If recovery has actually resulted, the Judge states that there will be no decree except at the lady's own instigation, but if, on the contrary, the insanity continues, the Court will be prepared to act on the conclusion it has formed.

---

#### THE LONDON OBSTETRICAL SOCIETY AND MR. BAKER BROWN.

THE Fellows of the Obstetrical Society are now in possession of certain extracts from the published matters concerning the operation of Clitoridectomy

as proposed by Mr. BROWN. These extracts are taken from various papers and articles that have lately appeared in the MEDICAL PRESS AND CIRCULAR, and therefore it is needless to refer to them. Appended to them are certain remarks of the Council, in which they point out on what (among numerous grievances contained in the said extracts) they specially rest the weight of their case. They also point out in the same remarks why Mr. BROWN is not in a position to say anything that can be satisfactory to the Fellows in his own defence.

It is the duty of Mr. BROWN to make a rejoinder, and show, if possible, that the charges are magnified through the irritation of his medical rivals, and that he has been actuated, on the whole, in what he has done by an earnest regard for the welfare of his patient, and the honour of his profession.

We wait for what he has to say in reply with anxiety, and we hope, in the interest of justice, that the Fellows who are for the moment jurors will candidly estimate what Mr. BROWN may say in defence, and that they will let no feelings of jealousy or faction—and in questions ardently disputed, such feelings may obtain entrance into the minds of honourable men—interfere in any degree with the verdict that conscience will suggest. For ourselves, we propose to delay publishing any special criticisms on the charges against Mr. BROWN.

This will give us the opportunity to hear the other side, as well as to avoid the invidiousness of making remarks on a pamphlet which, though printed and circulated among all the Fellows of a large Society, and which cannot possibly be therefore any secret to any member of the Profession, is yet called "private and confidential."

In this painful affair our main objections have been specially directed, not so much against the mere investigation of the charges, which may be proper enough if carried out in a right spirit, as against the manner in which these investigations have been actually effected. To us, we confess, it seemed a blow to the independence of the Profession and the honour of its individual members. "Private and confidential" seems the order of the day; "private and confidential" was the manner in which the charges were first composed; "private and confidential" the judges charge to the jury; "private and confidential" the manner in which the jurymen, each separate from the other, are requested to arrive at their determination; and "private and confidential," as well as rapid and decisive (for it must be done, says the *Lancet*, in one evening), the manner in which the sentence is to be given—the only public part about the whole proceeding being the disgrace and dishonour which may fall upon the character of one hitherto considered a respectable Fellow of the Society.

---

## Notes on Current Topics.

**ST. BARTHOLOMEW'S HOSPITAL.**—H.R.H. the Prince of Wales has accepted the Presidency of this ancient charity. Other changes than those we named last week have become necessary on the staff, in consequence of the retirement of Mr. Wormald, the senior surgeon. There seems to be some doubt whether the liberal course in respect to special departments, to which we alluded last week, will after all be carried out. It would, however, be very gratifying to find St. Bartholomew's leading the way, especially that it has just now secured the heir-apparent as President.

**INTERNATIONAL MEDICAL CONGRESS.**—We have been requested by the general secretary, M. Jaccoud, to announce that Dr. Beigel, of Finsbury-square, has been appointed as London Correspondent-Delegate of the Central Committee, and that he will be happy to receive the names of those gentlemen who may wish to take part in the forthcoming congress, of which we have already published the programme.

**THE ORDER OF THE BATH.**—The *London Gazette* of the 15th instant contains a series of promotions, all of which are conferred for actual service before the enemy. Four military and five naval surgeons have been made C.B. The only complaint we have to make on the subject is against the niggardly manner in which distinctions are awarded to our profession. Do these nine promotions really represent fairly our due? Is it not strange that we have only one K.C.B. on the list, and that the profession is excluded altogether from the rank of G.C.B.? When will Governments appreciate the services of medicine and surgery?

**DR. LIVINGSTONE.**—Nothing certain has yet transpired with regard to the report which reached this country of the death of the African explorer. There is still ground for fear that the report may be true, though, on the other hand, we may cling to the hope that Dr. Livingstone may yet be alive. It appears that no dependance can be placed on the evidence of the men who say that "they saw their leader dead," as it was found from other sources that they abandoned him when he was about to enter a Mazite-haunted district. "The case, therefore, must rest in awful suspense until some one of his faithful negro attendants, who, it is said, escaped the slaughter, shall return to confirm the tale of the Johanna men."

**RAILWAY INJURIES AND THE PROFESSION.**—A case was tried before Lord Chief Justice Bovill, the other day, in which some points will no doubt be of particular interest to our readers. A young woman, named Marshall, proceeded against the North London Railway Company for damages on account of injuries sustained while a passenger on their line through alleged neglect of their servants. The most important feature of the case was, that both parties had agreed to accept the evidence of Mr. John Adams, the Senior Surgeon to the London Hospital, as to the injuries which the plaintiff had sustained, and that gentleman, therefore, gave evidence on the point. Certainly it is more creditable to the profession for one distinguished surgeon's testimony thus to decide a case than to witness, as we too often have done, an array of conflicting medical evidence retained on each side. There ought

to be no difficulty in any case of this kind in accepting the impartial opinion of an experienced man, and, apart from the position he has long held at one of the largest of the London Hospitals, it is well known that Mr. Adams, as surgeon to several railway companies, has long enjoyed peculiar opportunities of forming an estimate of such cases. We are, therefore, very glad that in his summing up the Lord Chief Justice commended the course taken by the counsel on both sides in respect to their agreeing to accept the opinion of Mr. Adams, and suggested that it might form a very useful precedent. His Lordship added with great truth that "nothing could be more painful and perplexing in cases of this character than to have to determine upon the conflicting testimony of medical witnesses on both sides." One other point worthy of notice by professional readers is, that the company, with an illiberality in strange contrast with their conduct in the other part of the case, made a "bone of contention" of the surgeon's bill, which amounted to £60. It transpired that this gentleman, whose name we did not learn, lived fourteen miles from the patient. Each visit, therefore, involved a journey of twenty-eight miles, and as the attendance extended over a twelvemonth, it could not be considered heavy by any reasonable person. On this point also we are glad to find Lord Chief Justice Bovill disposed to act fairly by our Profession. He observed that "he did not think the jury would tax the surgeon's bill; he did not think the visits were too numerous; and the distance was so great that four or five hours were occupied on each occasion." Medical men have so often had occasion to complain in such matters that it is only just to signalize such an example of fair play. We sincerely hope it may be generally followed.

**THE ROYAL SOUTH HANTS INFIRMARY.**—The controversy at Southampton, to which we have more than once directed attention, continues to rage as acrimoniously as ever. The letter from Dr. Hearne, which appeared in our columns last week, is worthy of perusal by every one interested in the management of our provincial Hospitals. We are happy to accept Dr. Hearne's corrections as to matters of fact, as we should equally be open to correction from his opponents. As to matters of opinion we have several times expressed our views, which, if they do not exactly accord with those of either of the parties into which our Southampton brethren are divided, accurately represent, we believe, the feelings of the immense majority of the profession. We should be very glad, indeed, to find both parties abandon all personality, relinquish unkind suggestions respecting professional brethren, and unite their energies, to effect the reforms we have pronounced essential to the well-being of the charity.

**THE "TELEGRAPH" ON EXPERTS.**—Coarseness of language is not unfrequently assumed by a class of persons who desire to thrust their opinions down every one's throat, and whose chief delight is to "bully" the rest of the world into submission. Presuming upon the quietude with which many endure their presence, they are apt to indulge in vulgar abuse when least called for, and, without any occasion for suspicion, blurt forth accusations which, though a few meek men suffer in contemptuous silence, are a source of deep annoyance to others, and deserve severe reprehension. Unfounded charges against whole classes are safer to the utterer than those against individuals, but they concern the public press and must occasionally be noticed. The *Daily Telegraph*, in a leading article on a recent trial for

murder, last week indulged in an attack upon "experts" which it is not necessary to characterise. The voracious journal in question asserts that "there are certain ingenious chemical experts in London and elsewhere who can generally manage to find blood, or mud, or strychnine, or starch, or arsenic, or shellac, in anything that is submitted to them for analysis." The next paragraph speaks of "scientific witnesses, whose direct interest it is that their labours should secure a conviction." We protest against this wholesale accusation of crime against "chemical experts," and we are convinced that the assertions of the *Telegraph* will fail to satisfy the public that scientific witnesses are ready to perjure themselves for the sake of what, in such a case, would be worse than the word "blood-money" usually implies.

EDINBURGH UNIVERSITY.—There is a prospect that the Chair of Anatomy at this University will be filled by a worthy successor of the late lamented Goodsir. Among the likely candidates we have already heard of Professor Struthery, of Aberdeen; Mr. Turner, who for some time acted as Deputy for Professor Goodsir; Dr. J. B. Pettigrew, of the London College of Surgeons; Professor Redfern, of Belfast; and Professor Cleland, of Galway. We have no doubt that whoever may be selected will devote his best energies to sustain the reputation of the Chair.

THE MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS IN IRELAND.—A special meeting of this Society will be held on Wednesday evening, the 27th, to receive and consider a series of reports from the several cholera hospitals of Dublin. Chair to be taken at half-past eight o'clock. The following resolution has been adopted by the Council of the Society:—"That on the special cholera night the time allowed for the reading of abstracts from the several reports, and in the debates thereon, to each member, be limited to ten minutes." We hope to lay before our readers a full report of the proceedings of this meeting in our next issue.

PUBLIC SCHOOL REFORMS.—A correspondent of the "*Sunday Times*" in a series of able letters has remarked upon the many reforms needed from a hygienic point of view in public schools. The letter upon the insufficiency of diet recalls vividly to our recollection the time when we were subjected to this unwholesome discipline. It is well understood by the profession that good nutritious food is essential to the development of the frame, and we are glad to see the point exciting attention in a popular journal.

THE Royal Zoological Society of Ireland, in contemplation of purchasing some pelicans, have made inquiries as to the safest and best method of feeding them while on their sea voyage. Mr. Bartlett, the experienced superintendent of the Royal Zoological Society's Gardens at the Regent's Park, replies as follows:—"We have a fine Australian, which was fed upon the cuttings of poultry and other garbage from the butcher's shop. I lately sent some fish-eating birds out to India in charge of my son, and we sent on board a good stock of live frogs in a box of wet moss, a good number of live eels in a tub, almost without water (I find they live longest so packed), and I suggested, should the supply run short, to mix a few sardines in chopped meat, and I have heard he has succeeded in reaching Suez safely."

NEPOTISM IN THE ARMY MEDICAL SERVICE.—We observe in the Official list of Assistant-Surgeons gazetted to Regiments the following announcement, "Royal Horse Guards: Staff Assistant-Surgeon John Astley Bloxam to be Assistant-Surgeon, vice John C. Agnis deceased." The name of this gentleman appears in the list of candidates passed at the late Chelsea Examination, ranking fourth with a gross total of marks of 2120. In the ordinary course Mr. Bloxam should have passed this examination, and then proceeded to Netley Hospital for his probation of six months. He should then pass a second or promotion examination before being gazetted. This is the course which every other gentleman in the list will be obliged to pursue, but we understand that Mr. Bloxam has been permitted to enter Netley without the essential previous examination, and after his stay there, to present himself for the primary examination which he ought to have passed in the first instance. Furthermore, he is now gazetted without having gone in for the second or promotion examination at all, and, consequently, he is placed six months in seniority of those Medical Cadets who passed the same day as he did. We believe our information to be strictly correct, and if so, this gentleman's promotion is a very gross instance of official favouritism. It is simply "Remember Dowb" over again. Mr. Bloxam should not have been allowed to enter Netley without passing the primary examination; nor, having done so, to present himself for that examination at all; nor, on the strength of that examination, had he any right to be gazetted without the promotion examination, or to be promoted over the heads of his competitors as he has been. If the system of competitive promotion in the Army Medical Service is to be carried out only in the case of gentlemen who have no friends in Whitehall or Downing-street, the sooner its expensive machinery is laid by the better for the public service.

NEW PHARMACEUTICAL PREPARATION.—BEDFORD'S COD LIVER OLEINE.—The unpleasant nauseating qualities of the common preparations of cod liver oil have created a demand for some less repulsive form in which to prescribe this valuable agent. Bedford's cod liver oleine is one of the preparations put forward with this object, and the patentees have fully succeeded in meeting this objection to the usual form of the oil. The therapeutic powers of Bedford's oleine have yet to be tested and approved, but its merits in respect to appearance and taste are manifest. It is a very elegant preparation, perfectly clear and inodorous, and with no more taste than is inseparable from any oil. We have tested it in practice, and find that it is taken readily, and never causes nausea. Our experience does not enable us to say whether its medicinal properties are in any respect deteriorated. It is still a moot question whether the oil itself or the iodine and other minor ingredients are of greatest therapeutic value, and we have no reason to believe that Bedford's oleine has lost in any of the essential principles in the process which converts it into so attractive a medicine.

If the Reform Bill now before Parliament become law, all graduates of any University in the United Kingdom and all medical practitioners registered under the Medical Act, will be admitted to the franchise. The University of London will also return a member. These certainly, even if there be none other, are good points in the measure.

## Proceedings of Societies.

### SURGICAL SOCIETY OF IRELAND.

MARCH 1, 1867.

Dr. BUTCHER, President of the College, in the Chair.

#### CASE OF RECURRENT FIBRO-CYSTIC TUMOUR; FOURTH RECURRENCE IN THE SAME SITUATION.

Dr. DAVYS, of Swords, in presenting this specimen said— I have the honour to lay before the Society this evening a specimen of fibro-cystic tumour which I removed from the arm of a young woman, aged about 21 years, at my dispensary in Swords, on last Tuesday.

It occurred to me as a case not devoid of interest to bring before the Society this evening, inasmuch as this is the fourth time since February, 1865, that the patient underwent the operation of removal of a tumour, and from exactly the same position on the arm, about two inches above the external condyle of right humerus. In March, 1865, I had the honour of laying before the Society (as reported in THE MEDICAL PRESS of March 22 of same year) the specimen of the first large tumour removed. It then occupied the attention of the Society, and an interesting discussion ensued as to its being malignant or non-malignant; and as I observed that some of the surgeons present, to whose opinions I of course bow with all deference, were inclined to believe it malignant, I made it my special business to look after the subsequent history of the development of the tumour, and I must repeat my humble opinion again as to its being non-malignant. The patient from whom I removed the tumour now before you, and on whom Dr. Mapother also operated in St. Vincent's Hospital last December, is a stout healthy-looking young woman, presenting no cachectic features whatsoever, or evidence of glandular contamination. She observed, when about four weeks dismissed from St. Vincent's Hospital, that a tumour was reforming in the old cicatrix: I should add that on the 18th of May, previous to last December, I removed a tumour from the same place, and published the details of it in illustration, as to the operation, of the value of Richardson's Ether Spray Producer in nullifying all pain. The patient applied at my dispensary in Swords on 22nd of last month, when I was surprised to see that the tumour had so rapidly increased in size. I recommended her, as she is a pauper, to seek admission again into hospital, and as she positively refused to do so, and at the same time stating she did not for several weeks feel recovered from the effects of being put under influence of chloroform, I was induced, at the earnest solicitation of the patient and her friends, to remove the tumour. In doing so I again resorted to the ether spray, but I must say not with as good success as on 18th May previously, when on removing a tumour from the same arm, she assured me she felt no pain till sensibility of the parts was returning. This may be due to the greater size of the tumour on this occasion. Having made a long free incision over the tumour I removed it, or rather them, easily, as you may perceive smaller tumours surrounded the larger one. There was very little hæmorrhage. I regret I have not an opportunity of submitting a portion of the present tumour to a microscopical examination. The photographs I have the honour to submit were taken of the tumour and the patient a few days before its removal. They were executed with a great degree of care by the eminent photographer, Mr. Simonton, of 42, Grafton-street. Their very great accuracy in my opinion illustrates the great value of photography in similar cases.

Mr. RICHARDSON said he had examined two of the former specimens exhibited by Dr. DAVYS. They were good examples of fibro-cellular tumours.

#### A CASE OF ACUTE LARYNGITIS

Was exhibited by Mr. HARGRAVE, who spoke as follows:—

Mr. President, the pathological specimen which I have the honour to present to the Society has some points of interest

which are not unworthy of their consideration. It is the larynx of a man æt. 30, and married, who died of acute laryngitis in the City of Dublin Hospital. He was admitted into the hospital on the 18th February, Monday, suffering from this affection in a very acute form, accompanied with bronchitis. The breathing was very stridulous. He maintained himself in the erect position to assist his respiration, which, in the right lung was audible and natural, not so in the left which was feeble when compared with the right one; the chest was resonant; on looking at his countenance; there was no pallor, nor distress in dilatation of the *alæ nasi*, so constantly seen in severe attacks of laryngitis. The lips presented a natural colour, showing that sanguification was being healthily performed. On examining the epiglottis, it was soft and pliant, not rigid. The only place he complained of pain was immediately above the great cornuæ of the *os hyoides*.

The treatment consisted of *free leeching* in the vicinity of the *os hyoides*, poulticing after they fell off. Calomel and Dover's powder administered every third hour. These measures afforded great relief. In between twenty-four and thirty hours he was under the influence of mercury. On the 19th he was much improved in his breathing, and the stridor was much diminished. Continued the medicines, and strong beef-tea was given to him, having taken scarcely any nourishment before he came into hospital. On Thursday night, 19th, he was seized with sudden dyspnoea, which was much relieved by turpentine stupes round the neck. On the 20th and 21st, gums very sore, the mercury was discontinued. Chlorate of potash gargle, prescribed on the 22nd. Emp. vesicat. lyttæ to the nape of the neck, to be afterwards dressed with ung. Hyd. and sabinæ. The linim. camph. co. to the anterior part of the throat. On the 23rd, at the morning visit, no improvement; symptoms stationary. He passed through this day as the day before; between 9 and 10 o'clock P.M. a sudden change was evident; breathing more difficult. During my unavoidable absence my colleagues, Messrs. Tufnell and Croly, kindly attended for me; no time was lost in deciding on the operation of tracheotomy, which was performed by Mr. Croly with some relief—the patient survived till 10 A.M. of the 24th. He lost very little blood during the performance of it. Post-mortem appearances.—The larynx, trachea, and lungs on being removed presented the following changes: the lungs were congested at their posterior and phrenic surfaces, more in the left than the right; the bronchi showed evidences of inflammation in their mucous membranes, the trachea was similarly affected; the larynx exhibited the epiglottis thickened, reduced in size and rigid, the *cordæ vocales* also thickened, and the sinuses of the larynx much diminished in depth, and considerable submucous œdema of the entire of the larynx. So far there was nothing unusual from the ordinary appearances of acute laryngitis; but on cutting down to the posterior part of the cricoid cartilage, an abscess was found over the entire of the cricoid posteriorly. It was opened. It contained very fetid matter of a greenish colour, and was partly occupied by necrosed cartilage, also ossific formations into which the cartilage was being converted.

This occult abscess was the cause of the severity of the laryngeal affection under which the man finally succumbed. The notes of this case were carefully taken by Mr. Cranny, one of the resident pupils.

#### POPLITEAL ANEURISM; AMPUTATION; RECURRENCE OF THE DISEASE IN THE STUMP.

By EDWARD HAMILTON.

Jeremiah Sheehan, aged 45, a pensioner, was admitted to Steevens' Hospital on the 22nd of February, presenting some remarkable symptoms. He sat up in the bed, propped with pillows, apparently suffering from oppression of breathing. His face was congested; his lips blue, and the general surface of the body was cold, and marked with dark spots of congestion, of a purpuric character. The pulse was very weak, almost imperceptible. The heart's action was extremely feeble, and its sounds indistinct. He

had undergone amputation of the right thigh, and the appearance of the stump was very peculiar. Its surface was discoloured, of a livid hue, which extended some distance up the abdomen; it was cold to the touch, and had a peculiar brawny tense feel; two small openings existed on its anterior surface, from which issued a slight oozing of dark fluid blood; they were plugged with coagula; no pulsation or bruit could be detected in it.

His general symptoms were considered to be due to advanced cardiac disease, rapidly approaching a fatal termination—the condition of the stump being attributed to the formation of a diffused false aneurism. During the examination he was moribund.

Stimulants were freely administered, but they failed to arouse the vital powers, and he died in a few hours after admission. It was with great difficulty, and only after patient investigation, that I was enabled to glean the following facts respecting his previous history:—

While in the army he was four months under treatment by compression for a popliteal aneurism, and was discharged uncured. Returning to Cork, his native county, he entered the South Infirmary early in June, remaining until August, when he left, against the remonstrance of his medical attendant (Dr. Tanner). He remained at home until November, when he entered the North Infirmary. This he also left without permission, and lived at home for a few weeks. He then was admitted to the Workhouse Hospital, where, as his comrade states, the limb “mortified.” He was transferred to the South Infirmary, where his thigh was amputated by Dr. Tanner in December. He remained in hospital until last June, when he came to Dublin. He has since been most intemperate, constantly getting drunk and falling on the stump, and otherwise injuring it. I have been favoured, through the kindness of Dr. Edward Townsend, with the following particulars of the case while under his care in the workhouse, so far as he recollects them:—

“I found him in the Workhouse Hospital suffering from extravasation of blood, consequent on the bursting of a popliteal aneurism. As well as I recollect, his heart was very much enlarged, with well-marked double bruit, and the entire arterial system gave evidence of disease. He was removed by my direction to the General Hospital. At consultation I recommended amputation as the only chance left for the patient, and I think I felt it my duty to tell him at the same time that I feared he may not survive the operation.”

On examining the stump, the entire superficial femoral was involved in a diffuse false aneurism burrowing through it. The profunda was healthy, and carried its blood for the nourishment of the parts. The cavity contained much laminated fibrine. I regret that I was not able to obtain the heart, which circumstances, over which I had no control, perverted me doing. His comrade states the stump did not cause him much trouble until about a fortnight before his admission.

They had now the stump before them, and they could see the pathological conditions that existed—viz., a very large diffused aneurism evidently involving the entire extent of what remained of the superficial femoral artery, while the deep femoral remained in its integrity, supplying and nourishing the limb. The profunda vein could be seen distinctly. The whole of the cavity was occupied by a mass of clotted blood, some fluid of course contained in the very centre.

On raising off the skin of the stump they could see the femoral trunk—the common femoral tolerably safe as far as regarded its bifurcation. They would observe a small piece of bougie in the profunda artery, which was perfect, and the vein also was perfect. The entire mass was filled up with clots of blood, a good deal of lymph and fibrine coagulum covering over and protecting the vessels.

He regretted that he had been unable to get the heart, but he thought it better to bring the case before the Society in its imperfect state rather than that it should be lost, as he thought it a case of some surgical interest.

Mr. TUFNELL observed that Dr. Hamilton had called his attention to the fact that he saw this case two years ago. He was asked to see it in consultation with Dr. O’Flaherty in Dublin. It was an aneurism, the walls of which had receded until it had acquired about the dimensions of a blue plum. It remained at that size without becoming consolidated, and with a slight pulsation throughout it. Compression was kept up for a considerable time without any diminution or increase of the aneurism. The man was therefore allowed to walk about, and the tumour remained in a latent state—very much in the condition of the case under the care of Professor Porter—which ultimately got well. Another case under the late Mr. Smyly—viz., that of a man who was a schoolmaster, whose aneurism remained stationary for a long time, and then suddenly consolidated. Another case—that of a medical man who returned to his professional avocations in the country, and was riding when he felt some pain, put down his hand and found that the pulsation had ceased by detachment of the fibrine—recovered. This was a case of the same kind where the aneurism became lined with fibrine, leaving a small channel for the blood to pass through. He had lost sight of this man, and did not hear anything of the case until Dr. Hamilton called his attention to it, and told him that he intended to bring it forward. He wished to ask Dr. Hamilton if he heard any history of the man between the time of his leaving Dublin in 1835 and going into Steeven’s Hospital; whether the secondary aneurism had been noticed in the meantime, and whether any treatment had been resorted to?

Dr. FLEMING said this subject had been discussed so largely on former occasions, that it was unnecessary to enter into any details. With respect to the treatment of these cases he had some experience of the treatment adopted in the case of Dr. Molloy. He was treated in Steevens’ Hospital under Mr. Cusack, and like a great many others, treated by compression, he got quite dissatisfied, and would not submit to its continuance, and when he left town all the local symptoms of aneurism were still present in the popliteal space.

Mr. TUFNELL said that after Dr. Molloy returned home the aneurism was cured, and by some sudden effort in controlling his horse the fibrine got detached. Mr. Molloy died afterwards, but the popliteal aneurism was cured before his death, and he died of aneurism of the aorta.

Dr. BANON said he saw the present case on the morning of the man’s death. He was then in a moribund state, and no operative proceeding could have possibly been undertaken. He should wish to ask Mr. Hamilton this question. Supposing the arterial system was in a better state, and the man possessed of sufficient vitality, was there room to tie the superficial femoral, or would he have to tie the deep femoral or adopt any operative proceeding?

Dr. HAMILTON said he believed the man had received no treatment after he left Dublin, and as far as he could learn he had not suffered much until a fortnight before he was admitted to Steevens’ Hospital. Thus there was a tumour formed, and some slight bleeding from the openings on the face of the stump. With respect to the question of Dr. Banon, he was sure he would agree with him, that operative proceedings were out of the question in this case. In the first place there was no bleeding; the man was not dying of hemorrhage, but rather of cardiac disease in a very advanced condition. Then taking into account the state of his arterial system, it would be unsafe to tie an artery when an aneurismal tumour had formed in it twice. In other cases it might be the duty of the surgeon to give the patient a chance for life by tying the external iliac, rather than the common femoral. It was always advisable to go as far as possible from where the disease had been formed in an artery, and if the patient’s condition had admitted of it, it would have been their duty to give him what little chance the ligature of the iliac vessel would afford. But that was out of the question in this case.

## GUTTA-PERCHA URINAL FOR INVALIDS.

Mr. TUFNELL exhibited a urinal, which he said he had found very useful in a case which had been seen by the President during life. It was an instrument which gave a great deal of relief to the unfortunate individual who necessitated its invention, and as it might be found useful in similar cases he thought it desirable to bring it under the notice of the Society. The patient was an old gentleman, between 70 and 80 years of age, the subject of prostatic disease, the subject of stricture, and of abscess in the prostate, with small calculi in the bladder which came away during life, afflicted with enlarged testicles and tumid scrotum, and had a very short penis. The consequence of this was very severe suffering. The thickened bladder was unable to contain much urine at a time, and as soon as the patient obtained a little sleep the urine dribbled away, passing over the scrotum and integuments of the groin; but if he awoke, the moment he attempted to expel the water, from the shortness of the penis, it spouted upwards, just as the water might be observed coming from the pipes in the street when the water-cock was opened. The urine passed over the pubis and down the thighs, producing a vast amount of suffering. Every kind of urinal was tried for this unfortunate gentleman, but totally without effect. The size of the scrotum was such, that the penis became, as it were, rudimentary, and there was no means of attaching a urinal to it. Mr. Tufnell, with the assistance of Mr. Robertson of Batchelor's-walk, made the rough-looking instrument they saw before them. This gutta-percha apparatus was moulded over the thighs and the pubis, and made so that the penis and scrotum could pass into the upper opening. This aperture was plugged with raw cotton, and then the scrotum being well lubricated with an opiate ointment, the urine was conveyed away through the india-rubber tube, which passed through a hole in the bed, communicating with a vessel placed below. There was no valve in the instrument. The urine, as soon as it was emitted into this apparatus, instead of passing backwards, went into the tube and was carried away, and contributed months of comfort to the individual. Mr. Tufnell showed the bladder, and observed that it did not contain a single calculus after death, although during life several small ones had come away.

The PRESIDENT thought the suggestion thrown out by Mr. Tufnell for the construction of a urinal to meet such distressing cases as that he had described was most important. There was not a member of the Society who had not met with cases where, from old age, a paralysed condition of the bladder, and the penis shrivelled up and small, with the scrotum in an oedematous state, there was the greatest difficulty in preventing the water from trickling down the thighs and getting round to the back, scalding, teasing, and irritating the patient. The unfortunate subject of such an affliction was in a state of constant suffering, bed sores formed quickly, and the case was aggravated in every way. He had himself used several kinds of apparatus in such cases. In using the apparatus now before them, it would be necessary that the scrotum should be anointed to prevent the water irritating the scrotum; but if the water was prevented from dribbling down by a mechanical appliance of this kind, the patient's suffering would certainly be relieved in a marked way, and his life might be prolonged by preventing the death of the parts which would otherwise take place by sloughing. He knew nothing more difficult when the penis became shrivelled than to provide for the catching of the water. There were urinals invented for the penis, but in these cases there was no way of attaching it.

Dr. F. KIRKPATRICK said he had an old gentleman under his care at present, eighty years of age, who required the use of the catheter twice a-day. He had the infirmity referred to by Dr. Tufnell, and every apparatus to be procured in Dublin had been tried, but without effect. It was found impossible to keep him dry. He mentioned this to show how very necessary was some invention such as that exhibited by Dr. Tufnell. He had found, however, by ex-

perience, that when any part was enclosed in gutta-percha, the skin became soon excoriated, and he was afraid therefore the use of this instrument could not be long continued.

Dr. TUFNELL observed that if there was a free admission of air, the excoriation of the skin would not take place, and he showed that in the apparatus which he had contrived, there was an opening at the top to allow the natural evaporation of the body to escape.

The PRESIDENT repeated that the great object was to keep the urine away from the sacrum and the back. There were numbers of urinals which were very effective in many cases, but for such cases as that described by Dr. Tufnell this apparatus appeared to be most suitable.

Dr. STAPLETON observed that the anointing of the scrotum was troublesome, and he thought would produce irritation. He would prefer to dust the scrotum with lycopodium which he thought would be equally effectual in causing the water to run off. As had been observed, gutta-percha kept in the heat and the natural moisture. Decomposing urine would generate ammonia, which would certainly irritate the parts.

The PRESIDENT said there could be no difficulty in keeping the urinal properly cleansed and free from ammonia. The grand point was to keep the water away from the back.

## FEMORAL HERNIA OF UNUSUALLY LARGE SIZE.

Dr. FLEMING exhibited a drawing of femoral hernia of very unusual size in connection with the cast of the case of Mr. Colles, brought under the notice of the Society at a late meeting by Dr. Edward Hamilton. The subject of the drawing was a woman, aged beyond thirty years. She had been operated upon some few years previously for strangulated femoral hernia, and was subsequently most careless in wearing a truss, when, ultimately she was obliged to lay it aside altogether. On her application to Dr. Fleming, the hernia presented the appearance of an irregularly oblong tumour occupying the right inguinal region, passing somewhat over Poupart's ligament, and extending down to the centre of the thigh. The integuments at its most depending portion were inflamed and ulcerated, and in such condition, she was admitted into the Richmond Hospital. The essential features of the hernia were unmistakable. It was partially reducible, and contained intestine and large packeted masses of omentum. Its coverings in some portions were remarkably thinned, and the ulceration present was angry and irritable. The usual symptoms attendant on such class of hernia were present, and were specially distressing from any neglect in dietary or improper support of the projecting mass. The drawing is most truthful. The situation and appearance of the cicatrised integument, the size and course of the hernia, and the absence of any venous congestion beneath it are most accurately delineated—all tending to confirm the statements of Mr. Hamilton, and illustrating, as he remarked, the extraordinary accommodating powers of nature.

A bag truss, with a suitable lacing provision, gave great comfort to the woman.

The PRESIDENT observed that it was extraordinary that so large a tumour could exist without venous congestion. The pendulous character of the tumour was also unusual.

## HYDROCELE OF THE NECK.

Dr. FLEMING also exhibited a drawing of a remarkable case of hydrocele of the neck in a boy, aged 18 years. He gave a short outline of the prominent features of the case, and stated that details would be reported hereafter. Attached to the drawing was a sketch of the appearance of the fluid contained in the hydrocele. Cholesterine was present in large quantities in the fluid which was also shown.

The PRESIDENT said this case was one of considerable interest. It had many peculiarities. Its pendulous character was not usual. Then with regard to the supposed partitions in the tumour, that, too, was unusual. The inability to get transmission of light was not usual. These tumours were generally tense and tight, causing some difficulty in

making a diagnosis. The vascularity of the surface was also a peculiar feature.

Mr. CROLY said that a child was brought to the City of Dublin Hospital with a tumour situated in the submaxillary region. It had a feel exactly like a venous nœvus. The tumour was so tense and so much connected with the fascia of the neck that he could not isolate it sufficiently to try the translucency test. The mother stated that it appeared shortly after the child's birth. As he had great difficulty in coming to a correct diagnosis of the tumour, he made an exploratory puncture, and a quantity of fluid came out, which on microscopic examination was found to contain cholesterine and albumen. The tumour filled again, and when it became the size of an egg he put one of Chassaingnac's tubes through it, and the case terminated favourably.

Mr. COLLIS had seen a good many cases of hydrocele of the neck, and as to the point mentioned by Mr. Fleming, of the subdivision of the tumour, he had seen it occur not unfrequently; and in one case in which he operated last year—the subject being a young child—the cyst of the tumour had become very considerably hardened by what, as far as he could judge, was a cartilaginous deposit in its walls. That was a point worth noting in the history of these cases. He had seen tumours of this kind treated in various ways, and he would mention one case in which a drainage tube was used. The fluid was at first clear, like the ordinary fluid in hydrocele, but in the course of two or three days it began to be discoloured, and the friends of the patient were rather alarmed by a considerable flow of blood from the tumour five days after the insertion of the drainage tube. The child was brought to him, and at first he thought some vessel must have given way, but on a more careful examination he was led to think this hæmorrhage was due to a general weeping, and not the giving way of any one vessel. On removing the drainage tube and washing out the cavity the hæmorrhage ceased. They were indebted to Mr. Fleming for bringing forward this case of hydrocele of the neck, as surgical literature was rather scanty on this subject. He had treated them in various ways, by injecting them, tubing them, and in one case by excision. They all recovered. The origin of the tumour was sometimes in an ordinary strumous gland when it began to soften and break up and fluid formed. Some of the largest tumours he had seen had originated in an ordinary strumous gland.

Dr. FLEMING said that all the particulars noticed by the gentlemen who had spoken were detailed by authors in separate communications respecting the pathology of these tumours. Extreme mobility of the tumour was an index to its situation. When these tumours were placed superficial to the fascia, they might be moved in every direction. Some of these tumours were, strictly speaking, watery tumours. The watery tumour was accurately described by Sir Benjamin Brodie in his paper on watery cysts apparently connected with the liver. He also alluded to these watery cysts of the neck, which was frequently their seat, and in all those instances they were under the cervical fascia. In this case the tumour was quite superficial to the fascia, for so moveable was the tumour that they could pass the fingers behind it, and bring them almost together. He recollected an instance in which one of these tumours, apparently as innocent as this, was excised, and uncontrollable hæmorrhage took place within a short period after the operation, resulting in death. The integuments in the case under consideration were natural, with the exception of some small superficial veins on the surface of the tumour, but when the tension was removed by taking away the fluid the veins disappeared, and the colour of the integument was now as natural as that on any other part of the body, showing that this was a temporary effect produced by the tumour interfering with the venous circulation. With respect to translucency he had, in not a few instances, removed fluid exactly the colour of a strong infusion of coffee, perfectly black and filled with cholesterine. In sero-cystic tumours of the breast he had found the fluid sometimes quite dark. The

difficulty of diagnosis in cases of hydrocele of the neck arose from the relation of the tumour to the fascia; if superficial to it differential diagnosis was easy.

#### MEDICAL SOCIETY OF LONDON.

MONDAY, MARCH 18.

THE new President, Mr HENRY SMITH, took the chair this evening, and delivered an address, of which the substance was as follows:—

He felt it a very pleasing duty to thank the Fellows of the Society for having elected him to the chair, and he did so not as a mere matter of form, but with sincerity, and under the conviction that the honour conferred upon him was a mark of the favourable opinion of the Fellows at large; and he knew of no greater pleasure in his career than to possess the good will and esteem of the Profession, and especially of those in it to whom his character and actions were well known. He could not forget, moreover, that the Medical Society of London had enjoyed a great reputation for its usefulness, and for the numbers of eminent men who had from time to time been in its ranks; and although the Society had had its vicissitudes, he was glad to find that it was now in a prosperous condition. He referred to the many excellent researches which had been originated at this Society in the form of the Lettsomian Lectures, which had subsequently been published, and had attained deserved repute. He also referred to the utility of the Society, especially for younger members of the Profession; as it was essentially a practical Society, and no opposition was placed in the way of any Fellow, however young, who wished to bring forward his views on any subject. He strongly urged the younger members of the Profession especially to join its ranks, and as a practical illustration of its benefit, he might appropriately, now he had been elected to the chair, state his own history in connection with it. The first act in his own professional career was to join this Society, and he had been an active and interested member ever since: he had here made and cemented many friendships, had greatly increased his professional knowledge, and had been able, either in the form of papers or of lectures, to bring before the Profession his own thoughts and observations on various matters of practical Surgery, which had subsequently been extended, and had been the means of forwarding his professional career. "Therefore," said he, in conclusion, "I have a right to think well of this Society; and when I look upon the long list of eminent men who have filled this chair, I cannot but feel a strong incentive to make myself worthy of them, worthy of you, and worthy of the honourable position to which you, gentlemen, in your kindness have elected me, and the duties of which I will fulfil to the utmost of my power."

#### HARVEIAN SOCIETY OF LONDON.

At a meeting of the Harveian Society's "Committee for the Prevention of Venereal Disease," present—Dr. J. E. Pollock, President; Dr. Broadbent, Mr. Coote, Mr. Curguyen, Dr. C. Drysdale, Mr. Dunn, Dr. T. Fox, Mr. Gascoyen, Mr. J. Lane, Dr. Maudsley, Dr. Menzies, Dr. Meredyth, and Mr. Sedgwick, it was stated by Mr. James Lane that the effect of the working of the Contagious Diseases Act of 1866 had already been most striking in the lessening of the frequency and severity of venereal disease among the women sent into the Lock Hospital from Woolwich, as also among the soldiers quartered there. Although the Act had come into operation only in October last, the amount of disease was already only half of what it had been, and consisted almost solely of cases of gonorrhœa. The healthy women were now examined as well as the diseased. Mr. Lane added, that it must not be expected that the results would be so marked if this system were carried out among the general population. There were

forty Government beds for prostitutes at the Lock Hospital at present.

Mr. HOLMES COOTE stated that the result of the examinations of prostitutes at Portsmouth had been equally remarkable. The effect of compelling infected women to remain in hospital until cured had been admirable; and he thought that to grant such a boon to the public service and withhold it from the general public was an anomaly. It was suggested by Dr. C. Drysdale and carried unanimously, that circulars should be sent to the senior surgeons of all large hospitals in London, in the provinces, and in Ireland and Scotland, requesting them to inform the committee concerning the daily number of venereal cases treated at their respective hospitals; as to the proportion which those bore to the whole of the surgical cases treated, and as to the number of beds in their hospitals set apart for venereal cases. The propriety of instituting a system of police surveillance of notorious prostitutes and of periodically examining these women was then discussed.

Dr. POLLOCK observed that general public opinion in this country, he believed, was much opposed to the introduction of such a system.

Dr. MAUDSLEY said that the only cases that should be subjected to such interference should be those of *notorious prostitutes*.

Dr. BROADBENT approved of the system and laws in force in Malta, which the Honorary Secretary had read aloud to the meeting from the Government report, and which had resulted in nearly extinguishing contagious venereal diseases in that island. The ordinance of 1861 of Malta runs thus:—

"Article 1. Any person, being notoriously a prostitute, shall be liable to be visited, three times in each month, by one of the police physicians, for the purpose of its being ascertained whether such person is affected with venereal disease. The visit shall be made in a place to be for that purpose appointed by the superintendent of police.

"2. The person referred to in the preceding article shall be summoned to appear for the purpose of being visited as aforesaid, by means of an order in writing, signed by the superintendent of police, and stating the time and place in which the visit shall be made. If she refuse, she shall be punished with imprisonment for a term not exceeding three months, to be remitted as soon as she shall consent. If the physician find her diseased, she shall be kept in custody until cured."

Mr. Gascoyen, Mr. James Lane, and Mr. Holmes Coote, were all in favour of similar regulations being carried out, and they observed that this was more necessary to the welfare of the women themselves than even for the men.

Mr. SEDGWICK doubted the propriety of carrying out such measures.

Dr. MEREDYTH strongly advocated the system of police surveillance existing in France.

Mr. R. W. DUNN also was in favour of forcible examinations of all prostitutes.

Dr. MENZIES bore testimony to the value of such examinations from his own experience in the army.

After some debate, the following propositions were provisionally made:—

It was proposed by Mr. HOLMES COOTE, seconded by Dr. C. DRYSDALE, and carried unanimously—

- (1). "That the present hospital accommodation for female venereal patients is perfectly inadequate."
- (2). "That there should be sufficient district accommodation provided in all towns for the reception as in-patients of all women suffering from venereal disease."

Dr. TILBURY FOX considered that these two propositions would be readily acceded to by all who were acquainted with the existing state of things.

Mr. J. LANE said that the number of beds for venereal patients was quite inadequate, and only a portion of those who applied could be taken in.

Mr. GASCOYEN dwelt upon the sufferings of the women, who were frequently obliged to continue their trade, even

whilst suffering from severe ulcerations, owing to the present inadequate supply of beds.

The HONORARY SECRETARY read the following extract from the report of the late V. D. Committee, which said—"The Committee would have more hesitation in so earnestly recommending a periodical examination of public prostitutes under the act, and their seclusion until cured, did they not believe that in so doing they are acting, not only in the interest of the community, but especially so in that of the women themselves, with whom their profession has taught them deeply to sympathise; and were they not, moreover, convinced that such examination in nowise involves the legalisation or, in any respect, the encouragement of vice."

Mr. CURGENVEN, who expressed himself in favour of police regulation of prostitution, thought that the Contagious Diseases Act of 1866 should be applied to the whole of the population of the country.

After some debate, the following motion made by Dr. MAUDSLEY, and seconded by Dr. BROADBENT, was carried as a provisional one, subject to approval at future meetings:

"That the *principle* of police surveillance of *notorious prostitutes* embodied in the Contagious Diseases Act of 1866 should be applied to the population generally."

The Committee invite suggestions, which are to be sent to the honorary secretaries,

C. R. DRYSDALE, M.D., 99, Southampton-row, W.C.

J. B. CURGENVEN, Esq., 11, Craven-hill Gardens, W., London.

## Legal Intelligence.

HANCOCK v. PEATY.—JUDGMENT.

This was a suit instituted by the guardian of Mrs. Peaty, to have her marriage with the respondent, which took place on the 19th August, 1863, set aside on the ground that the lady was insane at the time the marriage was contracted. The learned Judge, in giving judgment, after going over all the facts of the case, stated that he did not intend at present to issue any decree, although, there could be no doubt that the lady had before and after her marriage, and, according to the evidence, on the very day of it, exhibited undoubted symptoms of insanity. But as Mr. Peaty asserts that his wife has now recovered and is in a sound state of mind, I do not propose to make a decree until the question is settled. If, upon investigation, he desires to have that question tried, the Court will give him every facility for that purpose. The suit was commenced by the petitioner, who claimed to act on the wife's behalf, on the ground of her being incompetent to act for herself, as long ago as July, 1866, and it may well be that between that period and the present she may have recovered. If this should prove to be the fact, the Court cannot proceed to a decree except at her own instance. If the insanity remains, the Court will be prepared to act upon the conclusions that it has formed.

## Correspondence.

### ABDOMINAL WOUNDS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Johnson's interesting and instructive case of protrusion of intestines through an abdominal wound, ending in recovery, which appears in the *THE MEDICAL PRESS AND CIRCULAR* of March 6th, reminds me of a still more severe injury of that kind which came under my own care here in April, 1852, and which also terminated in recovery, the particulars of which will be found by referring to the *Edinburgh Medical Journal* of July, 1852.

My patient, a boy of nine or ten years of age, is now a robust healthy man.—Yours, &c.

ARCHIBALD BLACKLOCK,  
Late Surgeon R.N.

Dumfries.

## MR. BAKER BROWN AND THE OBSTETRICAL SOCIETY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to congratulate you on the very independent and just manner in which you have referred to the controversy respecting Mr. B. Brown. He is a gentleman not personally known to myself, but from all I have heard of him I have gathered that he has stood high in the profession with regard to surgical skill, and that, up to the present time, no shadow has rested upon his character. It was, therefore, a matter of surprise to me when I heard of the course adopted by the Council of the Obstetrical Society, and I cannot but suppose that either some grave offence has been committed by Mr. Brown, whereby he has exposed himself to expulsion from a learned and honourable Association, or that some strange jealousy exists among the Fellows. I am necessarily ignorant of the real merits of the case, still your suggestions commend themselves to the common sense of every man. Justice demands that no one should be condemned unheard, and that the utmost publicity should be given to the investigation. This is the only way in which the Society can vindicate its proceedings. Let them show to the profession and the world that they are right in taking up the case as they have done, or let them honourably, like men and gentlemen, exonerate the accused from the suspicion they have brought upon him. Unless this is done, the profession generally will share more or less the obloquy which will unavoidably follow a negligent and partial decision.—Your obedient servant, AN OBSERVER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The question now before the Obstetrical Society is of little moment to me personally, but I hope, for the honour of the Profession, the Fellows will not adopt a course which would necessarily throw suspicion upon themselves. The real merits of the case are, of course, at present concealed from public view, but the *modus operandi* by which to arrive at a decision is, I think, open to the opinion of all. Very opposite views on this point are taken by different parties. You, sir, I perceive, advocate an open method of procedure, and consider that every facility should be given to the accused of justifying himself before the men who threaten his expulsion. This to me, who have no feeling on the subject, apart from a desire that justice should be done, seems exceedingly proper. I therefore thank you for the manly tone you have adopted in your leading columns. The *Lancet*, on the other hand, recommends closed doors when the Council meet, and that each Fellow should have made up his mind before hand from the "published matters" which have been sent him; and, of course, I argue that no defence, no explanation, no vindication of himself by the accused, however clear and convincing, should have the least weight with them; but their little rolled up slips of paper with "yes," "yes" upon them, meaning let him be sent to Coventry, should be dropped into the glass globe in sight of the President, and the matter, in two hours at most, be brought to a conclusion. It is strange that such advice should come from any writer in 1867, when we reckon it our honour and our safeguard to have open courts, and trial by a jury who are compelled to hear the whole case before deciding on their verdict. One would think he had been dreaming all along of the inquisition, or some equally arbitrary conclave. As to the *Medical Times*, it seems a little frightened at the state of things just now; at all events it holds its tongue, possibly judging it wiser to keep silence until the fray is over. But the power now underlying the *British Medical*, though it has changed places, appears still as waspish and ready to sting as ever. Having closely observed the tone of the medical press, I find that yours is the only really independent organ, which, without prejudging the point at issue, advocates a straightforward and honourable course.—I am, sir, your obedient servant,

FAIR PLAY.

## ON THE TREATMENT OF DELIRIUM TREMENS BY INDIAN HEMP.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—In your journal of 13th inst., Mr. Tyrrell, F.R.C.S.I., &c., has given notes of a case of delirium tremens treated by Indian hemp, and, as I had an opportunity of trying its effects in a case which came under my notice in February last, I can also testify to its efficacy. My patient got larger doses than those given by Mr. Tyrrell (3ss. omni secunda

hora) for the first day; and on the second day, its good effects were so manifest, that I discontinued its use. The patient had also bronchitis (the result of exposure during the commencement of the attack), but this was easily subdued, and in four days from my first visit, he was able to resume his occupation. In the concluding part of Mr. Tyrrell's communication, he says:—"That the use of Indian hemp has not been adopted in delirium tremens," and that "I do not find it mentioned in the books I have consulted." Dr. White, of Downpatrick, may have used it early in his career, but Dr. O'Shaughnessy in 1838 appears to be the first who brought Indian hemp into notice in this affection. Mr. Tyrrell will find, on reference to Waring's excellent work on *Practical Therapeutics*, all the information he may require.

Hoping, dear sir, I have not trespassed too freely on your valuable space.—I remain, yours, &c.

H. BROWNE, L.R.C.P.E., L.R.C.S.E.

## Medical News.

AN Odonto-Chirurgical Society has been formed in Edinburgh upon the principles of the Odontological Society of London.

THE cattle disease is on the decline in France. The number of cases was in the middle of February 1735, and 1607 only at the end of that month.

MR. P. H. HARPER has, we understand, resigned the office of surgeon to the London Surgical Home. Mr. Baker Brown is now, therefore, the sole remaining medical officer to this institution.—*Lancet*.

MR. KERBEY, the medical officer for the Dilwyn district of the Weobley Union, Herefordshire, was recently reprimanded for "giving away too much money to the poor." He said, in reply, that he was not a relieving officer, and gave mutton only where he knew it was required instead of medicine.

DEATH OF M. BOUDIN.—The devotees to statistical and anthropological studies will much regret to hear of the death of this elaborate investigator. Occupying a high position in military medicine in France, and the author of a standard work on Medical Geography, his contributions to the various scientific and medical periodicals on every branch of medical statistics have been as numerous as valuable. We hope to be able shortly to furnish some account of his labours.

THE CHILDREN'S HOSPITAL, DEVONPORT.—We are glad to hear that Sir Charles Locock and family have undertaken the support of, one bed in this hospital during the ensuing year. It must be peculiarly gratifying to the promoters of the charity to have such a practical testimony to its value from so important a member of the medical profession as Sir Charles Locock. The officers and crew of H.M.S. *Lord Clyde* have sent another donation of £6 17s. 6d. to the children's ward. With so large a proportion of its little patients the children of absent sailors, such a donation is a grateful acknowledgment of the services rendered to the children of messmates. We are inclined to think that were such donations more frequent, and the Children's Hospital developed to its fullest extent, "Jack" would pay fewer visits to the cemetery and more to the cot side on his return from abroad.—*Western Daily Mercury*.

FOR some time past the various towns forming "Sheerness" have been suffering from a visitation of small-pox. Great numbers of the inhabitants have been attacked by the fearful disease, and many have died. Lately the malady has appeared among the crews of the Queen's ships anchored in the harbour, and several of the seamen, marines, &c., have been attacked. Within the last two or three weeks a good many cases have been sent to Melville Hospital, Chatham, from the fleet at Sheerness. The sufferers were brought up the Medway in the *Fearless*, steam tender, to Chatham Dock yard, where they are landed, and thence conveyed to Melville Hospital. After some days had elapsed without any fresh cases being brought to Chatham, on Wednesday the arrival of a new sufferer showed that the fleet at Sheerness was not yet free from the scourge. The patient was a seaman on board the *Cumberland*, guard-ship of reserve at Sheerness.—*The Day*.

**MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.**—A special meeting will be held on Wednesday, 27th March, 1867. Tea at eight; chair to be taken at half-past eight P.M. Communications: Reports from the several Cholera Hospitals of Dublin. Resolution of Council, January 4th, 1867—"That on the Special Cholera night the time allowed for the reading of Abstracts from the several reports, and in the debates thereon, to each Member, be limited to Ten Minutes."

A TESTIMONIAL is on foot for presentation to Mr. Thomas Smith, who is about to resign the Demonstratorship of Anatomy at St. Bartholomew's Hospital. This is a spontaneous act, we believe, on the part of the students, and complimentary therefore in the extreme.

**RATING OF SCHOOLS AND CHARITIES.**—A meeting was held on Tuesday week at Willis's Rooms for the purpose of adopting measures to secure for schools and charitable institutions generally continued exemption from rating. The Earl of Shaftesbury presided, and there were present a large number of clergymen and gentlemen forming deputations from numerous metropolitan and provincial charitable institutions. Several letters of apology were read, among which was one from the retired Lord Chief Baron, stating that he rested the claim for exemption of charitable institutions and schools from rating, not on mere charity, but on justice. Resolutions were passed declaring it to be impolitic and unjust to subject these institutions to such charges, as the relief administered materially lessened parochial rates; and that the recent decision of the courts of law was contrary to the spirit of modern legislation, and tended to discourage educational effort. A deputation was also nominated to wait on the Premier.

## Notices to Correspondents.

Communications to the London Editor should be addressed to 20, King William-street, Strand; to the Edinburgh Editor, at MacLachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be legibly written, and only on one side of the paper.

*Inquirer.*—We can only refer you to the advertisement in our columns for the information you seek. Mining operations are not in our way. "The Nantymwyn Company" seems to be in very respectable hands.

*Dr. J. N.*—Not sufficiently explicit.

*Mr. Coulter.*—The address shall be altered as desired.

*F.R.C.S.*—We believe you can recover.

*Mr. L. Dalston* is referred to our columns of March 13th.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you be good enough to inform me what is the difference, if any exist, between a Member and a Licentiate of a College, as parties holding a Licence of the London College are styled the former, and of the Dublin College, the latter, also the different Colleges of Physicians.—Yours truly,

[The Membership and Licentiatehip are equivalent terms, the former being given in the London College of Surgeons, and the latter in the Dublin. In the London College of Physicians, both titles are given, and that of Member holds the higher rank.—Ed. M. P. & C.]

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As you are supposed to know everything, may I take the liberty of asking for an answer in the next number, whether, on dividing a large Dispensary district into two sub-districts, the present Medical Officer of the large district gets one of the sub-districts, that is, is he legally entitled to it without going through the form of being elected, or otherwise.—I am, sir,

AN OLD SUBSCRIBER.  
[Certainly. The Medical Charities Act, section. xiv., provides, "That where a Medical practitioner shall be in possession of a Dispensary, &c., &c., situate in the locality included in such new district, it shall be lawful for the Commissioners, if they think fit, to declare him one of the Medical Officers of the new district."—Ed. M. P. & C.]

## MEDICAL DIARY OF THE WEEK.

WEDNESDAY, MARCH 27.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Huxley, "On the Osteology and Dentition of the Sauropsida, or Reptiles and Birds."

ROYAL COLLEGE OF PHYSICIANS.—5 P.M. Lumleian Lectures: Dr. Russell Reynolds, "On certain Points in the Relation between Medical and Legal Practice."

HUNTERIAN SOCIETY.—8 P.M. Mr. Gowland, "On Cases of Fistula in Ano requiring different Methods of Treatment."

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.—8 P.M.

THURSDAY, MARCH 28.

ROYAL INSTITUTION.—3 P.M. Mr. Pengelly: "Geological Evidences of Antiquity of Man in Devonshire."

FRIDAY, MARCH 29.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Huxley, "On the Osteology and Dentition of the Sauropsida, or Reptiles and Birds."

ROYAL COLLEGE OF PHYSICIANS.—5 P.M. Dr. Burdon-Sanderson, "On the Mode and Duration of the Contraction of the Heart in Health and Disease."

ROYAL INSTITUTION.—8 P.M. Prof. Frankland, "On the Water-Supply of the Metropolis."

SATURDAY, MARCH 30.

ROYAL INSTITUTION.—3 P.M. Mr. Pengelly: "Geological Evidences of Antiquity of Man in Devonshire."

## MEDICAL APPOINTMENTS.

ARNISON, C., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Stanhope and Newlandside Districts and the Workhouse of the Weardale Union, vice G. Arnison, L.R.C.P. & S.Ed., deceased.

ARNOLD, R. O., L.F.P. & S.Glas., L.M., has been appointed Medical Officer and Public Vaccinator for the 4th District of the Chesterton Union, Cambridgeshire, vice Dr. B. Pinchard, non-resident.

JACOB, ARCHIBALD H., M.D., T.C.D., F.R.C.S.I., has been elected a Member of the Council of the Royal College of Surgeons in Ireland.

BALL, J. A., M.B., has been appointed House-Surgeon to the Stockport Infirmary, vice W. J. Wane, M.R.C.S.E., resigned.

BEBRELL, C., M.R.C.S.E., has been appointed Resident Medical Officer to the St. Pancras and Northern Dispensary, vice T. C. Shaw, M.D., resigned.

BLUNDELL, W., M.R.C.S.E., has been appointed Surgeon to the Chelsea Brompton, and Belgrave Dispensary, Sloane-square, vice T. Dickinson, M.R.C.S.E., resigned.

SMALLMAN, R. S., M.B., has been appointed Assistant Medical Officer to the Durham County Lunatic Asylum at Sedgefield, vice J. A. Campbell, M.D., appointed Assistant Medical Officer to the Cumberland and Westmoreland Asylum, Garlands, near Carlisle.

THOMAS, O. D., M.R.C.S.E., has been appointed Assistant-Surgeon to the 6th Monmouthshire Rifle Volunteer Corps.

WALKER, A., M.R.C.S.E., has been appointed House-Surgeon to the London Hospital, vice R. Ley, M.R.C.S.E., whose appointment has expired.

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

BLAIR.—On the 2nd inst., at Denholm, Roxburghshire, the wife of W. Blair, M.D., of a son.

BARBER.—On the 7th inst., at Ulverstone, the wife of H. Barber, M.D., of a daughter.

M'CARTHY.—On the 8th inst., at Mountjoy-street, Dublin, the wife of Edward M'Carthy, M.R.C.S.E., Staff Assist.-Surgeon Army of a son.

GILBERT.—On the 10th inst., the wife of H. Gilbert, M.R.C.S.E., of Princes-end, Tipton, Staffordshire, of a daughter.

THOMAS.—On the 11th inst., at St. Clears, near Carmarthen, the wife of J. Little Thomas, Surgeon, of a daughter.

SPENCE.—On the 13th inst., at Linlithgow, N.B., the wife of Robert Spence, M.D., of a daughter.

### MARRIAGES.

HILL.—KING.—On the 5th December, at Sandridge, Victoria, John James Hill, L.R.C.P.Ed., L.F.P. & S.Glas., late of Royton, Lancashire, to Jane, daughter of the late John King, Esq., of Huckforth, Yorkshire.

ADLEY.—ROSS.—On the 19th of January, at Barrackpore, W. H. Adley, Surgeon 17th Bengal Cavalry, to Evalina Ross, daughter of Major-General George Burney, Bengal Service.

### DEATHS.

LANSDOWN.—On the 27th of December, at Brisbane, Australia, aged nine weeks, Reginald Chas. Joseph, the infant son, and on the 2nd of January, Lucy, the wife of Dr. J. Ruscombe Lansdown, and daughter of the late Rev. Charles Emerson, of Llanfair, Cardiff.

GILCHRIST.—On the 12th ult., W. Gilchrist, M.D., of Lake House, Torquay, Devon.

LITTLE.—On the 16th ult., at Woolwich-common, J. S. Little, M.R.C.S.E., Surgeon-Major Royal Artillery.

WALKER.—On the 27th ult., R. Walker, M.D., of South Apsley-place, Glasgow.

WALTERS.—On the 2nd inst., E. S. Walters, M.R.C.S.E., of Leek, Staffordshire, aged 53.

SWIM.—On the 5th inst., D. E. Swim, M.D., of Earlstown, Warrington Junction, Lancashire.

FARR.—On the 13th inst., at Dunstable, Joseph Farr, Esq., aged 75. Mr. Farr commenced practice prior to 1815.

COLSTON.—On the 17th inst., at Husbands Bosworth, Leicestershire, Peter Colston, Esq., aged 57, for many years District Medical Officer of the Market Harborough Union.

Original Communications.

DESCRIPTION OF A STRICTURE DILATOR ON THE DOVE-TAIL PRINCIPLE.

By B. WILLS RICHARDSON, F.R.C.S.I.,

EXAMINER IN THE ROYAL COLLEGE OF SURGEONS, AND SURGEON TO THE ADELAIDE HOSPITAL, DUBLIN.

DURING a visit to Mr. William Oldham's studio, while he was occupied in engraving the illustrations for my communications regarding Perrève's dilator, he casually informed me it was his opinion that the blades of the dilator might be made to divaricate much more simply, while, at the same time, with equal security as they do by the mechanism employed in the welded instruments of Perrève, and that the dilator might be modelled of as small a calibre as in those instruments. He also stated that greater solidity might be obtained if the conductor were welded *its whole length* to the lower blade, instead of by one end only. A most important advantage while the instrument is being passed into the bladder, as well as when the forcer is being pushed home.

To prevent any misapprehension I shall here observe that I include under the name of Perrève, all dilators constructed upon his principle, having the conducting rod attached and fixed only at their vesical extremities.

Mr. Oldham's idea was, that the conductor should be formed like the male part of a dove-tail, and attached by its apex along the whole length of the middle of the upper surface of the lower blade; and that the forcer should be hollowed to correspond, having a slit in its under part, for the passage, or free sliding, of the narrow neck of the conductor.

An instrument constructed as Mr. Oldham suggested appeared to me to possess such solidity, and to be so well calculated to meet the objections of those timid surgeons who mistrust the movable conducting-rod of the Perrève dilator, that I requested Mr. Oldham to make an engraving of an instrument having a conductor of the dove-tail form.

Fig. 1 represents the modified dilator suggested by Mr. Oldham. It will be perceived that the grooved blades and one of the clamps of Perrève's dilator are retained, but that the conductor is triangular and attached by its apex along the middle of the upper concave surface of the lower blade. The conductor is pierced by a canal for the passage of the urine. The vesical opening of this canal may be placed either in the convexity of the beak, for Desault's button-ended wire guide, if required.

Mr. Oldham's modified Perrève stricture dilator and separate forcer, on the dove-tail principle. W. Oldham, Scp.

Fig. 1.

Fig. 2.

Enlarged vertical section of the component parts of the dove-tail dilator, with a separate piece of the forcer, to show the situation the passage for the conductor should occupy. W. Oldham, Scp.

Fig. 2 are enlarged representations of a vertical section of the component parts of the dilator, and a separate piece of the vesical end of the forcer, to show the exact situation of the passage for the conductor, and which it should maintain throughout.

Fig. 3.

If properly constructed and made of a well tempered material, it is not possible to conceive that an accident as regards disarrangement of the component parts of this dilator could happen during its use. The male and female parts of the dove-tail being so proportioned as merely to allow of easy sliding of the forcer along the conductor, the former must be maintained on the latter while the instrument is in action.

Since Mr. Oldham engraved Figs. 1 and 2, he has, at my suggestion, made some alterations in the instrument which appear to me calculated to facilitate its working.

They are seen in Fig. 3. The conductor I have had rounded, and attached through the intervention of a very narrow and shallow bar along the centre of the upper surface of the lower blade, as in Fig. 1. The conductor of this instrument may also be hollowed for the passage of the urine. The half handles are longer than those of Fig. 1. and are grooved transversely, above and below, for secure grasping.

The handle of the forcer has a shoulder to prevent the slipping of the finger and thumb when we are forcing it home.

One of Perrève's clamps has been likewise retained in my modification, to secure the proper relation of the blades when being divaricated.

Mr. Richardson's modification of the dove-tail dilator, with separate forcer. W. Oldham, Scp.

Fig 4.

Enlarged vertical section of the rounded dove-tail dilator, with a small portion of the forcer to show the situation the passage for the conductor should occupy.

W. Oldham, Sep.

Fig 4 represents an enlarged vertical section of the component parts of the rounded dove-tail dilator, and a separate piece of the vesical end of the forcer to show the exact situation of the passage for the conductor and which it, also, must maintain throughout.

In the above description I have spoken of the *welding* of the conductor to the lower blade. These portions of the instrument, however, can be formed otherwise; for, a well educated surgical instrument mechanic ought to be able to construct conductor and lower blade out of one piece of metal without any welding whatever, in the situation alluded to.

In conclusion I may observe that the handle can be shaped according to the fancy of the surgeon, and covered with ivory, if preferred to roughened steel.

I need scarcely say, that the internal corresponding surfaces of each half-handle should be grooved longitudinally, and that these grooves are to be continuous with the grooves of the blades.

Two different sized forcers, at least, should be supplied with the dilator.

#### NOTES ON A CASE OF PHAGEDÆNIC CHANCRE OCCURRING ON THE DORSUM PENIS,

ACCOMPANIED BY BUBO OF THE RIGHT SIDE, AND FOLLOWED BY CONJUNCTIVITIS, PASSING RAPIDLY INTO SCLEROTITIS AND ACUTE KERATITIS OF THE RIGHT EYE.

READ BEFORE THE ULSTER MEDICAL SOCIETY.

By ANGUS M. PORTER, M.D.

On the 16th of last December, A. C. M., a married mechanic, was brought to me for a sloughing sore on the dorsum of his penis, which he first noticed as a small abrasion a fortnight before. On examining, I found it to be about the size of a florin, the surface an ashy grey, discharging a greenish ichor; the edges ragged and high, and the base flabby, nonindurated. The cellular tissue of the prepuce was infiltrated to a great extent, but the dorsal lymphatics did not appear in the least implicated, nor had he at this time any sign of bubo in either groin. On questioning him as to his habits and health he told me he occasionally drank freely, was exposed to heats and colds, had a variable appetite, and was not accustomed to very good food. The bowels were regular. He was not aware of suffering from any complaint but the one for which he wished me to treat him, and was not aware of ever having had venereal disease before. He was in a painfully nervous state, and this he attributed to loss of sleep. He had been poulticing the sore on his own responsibility for several days, and had also drugged himself with senna and salts; his pulse was quick and thready, his tongue creamy, and his complexion sallow.

With the assistance of his companion, I put him slightly under the influence of chloroform, and freely cauterized the chancre with strong nitric acid; applied a piece of lint dipped in a mixture of glycerine and water, over this oiled silk, and a small, light bandage, in which I included the swollen foreskin; ordered him to keep a poultice of linseed meal to the sore during the night, and renew it next day; to support the yard on his abdomen by means of handker-

chiefs; and get to bed as soon as practicable. I gave him twenty grains of Dover's powder to be taken at eight o'clock, and prescribed five-grain doses of Plummer's pill, night and morning. On his leaving he appeared much more tranquil, the pain of the operation having almost passed away.

On Tuesday, the 18th ultimo, according to arrangement, he called with me; had of necessity been at his work the preceding day, but had not suffered much pain; had slept well during the night, and did not appear in the least agitated or nervous; his bowels had been freely opened in the morning; the ulcer was now deeper than the skin, and discharging thin yellow pus; the edges were high and the margin inflamed. Into the centre of the ulcer I dropped a little of the red oxyde of mercury, and having smeared the intact skin with a mixture of collodion and glycerine, applied a weak lotion of nitric acid, and bandaged up the penis against his abdomen. Prescribed the compound decoction of sarsaparilla, in one ounce doses, three times daily. Before he left, I found on enquiry a large bubo had appeared in his right groin—the side corresponding to the larger half of the chancre on the dorsum penis. I recommended a poultice of linseed meal to be kept to it, and the weak nitric acid lotion to be renewed to the chancre when required.

On Thursday, the 20th ultimo, the ulcer presented a red granulating surface, with healthy pus; the edges were less inflamed, and level with the sound skin. Ordered frequent applications of black-wash; the bubo was large and painful; I opened it, and obtained a good quantity of curdy matter, very dark coloured; he experienced great relief from this; I then painted the skin over and about with tincture of iodine; I stopped giving him the compound calomel pill, as he had now taken in all half a drachm of it, leaving him on the compound decoction of sarsaparilla as his only medicine.

Christmas day, the 25th ultimo, the ulcer was healing rapidly; his general health was good; he had been living more generously for the previous four or five days, and taking his food with relish; had slept well, and did not appear to suffer from febrile excitement.

On the 27th ultimo the new skin had begun to form from the edges, the bowels kept regular, and the appetite and spirits good; I painted the bubo with tincture of iodine; it had almost disappeared, as had the swelling of the prepuce.

On the 28th ultimo the ulcer was nearly healed, there being but the size of a groat of granular surface.

On the 29th ultimo the ulcer was covered with new skin, except a very minute patch; no traces of the bubo remained, save a little hardness. On this date he discontinued the compound decoction of sarsaparilla as recommended. He now left me, thinking he was cured.

On the fourth day of this month (January), he came back to me complaining of a sore throat; he thought he had caught cold, and evidently had. On examining his throat I found the uvula full and congested, with a similar condition of the right tonsil, and diffuse erythema of the fauces, but could not detect ulceration of any kind. He was feverish and nervous, and seemed to apprehend something unpleasant. Recommended frequent alum water gargles, and gave him a powder composed of two grains of calomel with twenty grains of Dover's powder, to be followed in the morning by a dose of salts; his bowels had not been acting for two days, and this condition seemed to aggravate his symptoms. Before leaving, he directed my notice to the smarting of his eyes, and congestion of the conjunctivæ, which, however, was very slight.

On the 5th inst. the chancre was quite healed; the throat was slightly better, but the conjunctiva of the right eye was greatly inflamed, that of the left eye less so; I touched the palpebral portions of the membrane with the stick nitrate of silver; gave twenty grains of Dover's powder; ordered two leeches to the temple, and dreading the possibility of syphilitic poison having something to do with this acute attack, immediately put him on the bichloride of mercury, prescribed in the following form:—

℞ Hyd. bichlor. gr. ii.  
Tr. hyoscyam. ℥iij.  
Vin. colchici.  
Vin. ipecac. aa. ℥ss.  
Infus. gent. co. ad ℥iv. M. ft. mist.

A teaspoonful to be taken in a glass of water three times daily as directed; recommended as nourishing food as his means would permit of, warm clothing, and, as far as possible, avoidance of exposure. He had to leave off work on this date, owing to the intense pain; his nervousness was excessive, and the application of the caustic seemed to excite him very much.

On the 7th inst., he came to me in great alarm, saying his eye was much worse; he was suffering extreme pain in the brow and temple, which at times he referred to the deeper structures of the ball; he had most marked photophobia of the right eye; the tears ran from both on examination, but principally from the right one, the left conjunctival membrane seemed much improved, and the congestion greatly lessened, but on the right side the inflammation had extended, and the subjacent tunic become involved, as indicated by the straight pink coloured vessels to the inner side of the cornea, which were visible for a limited extent, running from the margin of the blueish white ring, and terminating in the capillary net work of the conjunctiva; the pupil was at this time dilated. The soreness of the throat had passed away; his bowels were regular, but his appearance was haggard and worn from want of sleep. Ordered two leeches to his temple, and twenty grains of Dover's powder to be taken at bed time; the bichloride of mercury mixture he was taking regularly.

On the 8th inst. the inflammatory action of the left eye had disappeared, while in the right eye it had decreased in the conjunctiva, but increased and extended in the sclerotic to the inner side of the cornea, round which the blueish white ring had become more opaque; the cornea itself was still clear, with the pupil contracted. He had great dimness of vision; intolerance of light, and profuse flow of tears, supra-orbital pain, and severe headache, accompanied by a good deal of febrile excitement. Recommended a full dose of Dover's powder, and hot fomentations to the eye, the other treatment being strictly pursued.

The following day (9th inst.) he returned in a state of distraction, more, however, from the dread of evil results than any pain he suffered. On raising the lid I found the whole cornea had become opaque, completely obscuring the pupil, he could not see at all with this eye. The pink coloured vessels of the sclerotic were very distinct to the inner side, while very little congestion remained in the capillaries of the conjunctiva. Prescribed ten drops of the tincture of perchloride of iron every hour, the bichloride of mercury being continued as before, and as a collyrium:—

Ext. Belladon. gr. xx.  
Zinci Sulph. gr. xl.  
Aqueae distill. ℥iv. M.

The full of a small syringe to be injected under the lids four times daily, while with me I used some of this to his eye, and though painful at the time, he experienced great relief after it, accompanied by intense itching. Recommended a blister behind his right ear, and gave him a Dover's powder to take at bed time.

I did not see him on the 10th inst., but visited him at his own house on the 11th; his friends had refused to give him his medicines, or otherwise carry out my instructions. I then found it necessary to tell his wife the previous history of his case, in order that she might afterwards permit him to go by my advice. On exposing the eye, considerable congestion of the conjunctival capillaries, more diffuse and extensive inflammation of the sclerotic membrane on all sides, less opacity of the cornea, and a more dilated pupil, were the appearances observed; though the pupil was now apparent he could not in the least degree distinguish light from shade. The treatment was now resumed, and the blister applied.

On the 12th inst. I learned that all directions had been strictly attended to, the changes presented by the eye were more general redness of the conjunctiva, and deeper colour in the radiating capillaries of the sclerotic, the condition of the cornea remaining unaltered; his pulse was sixty in the minute, steady and full; his tongue clean; appetite good; and nervous excitement much less; his throat he did not now complain of, nor did it present an unhealthy state; on this occasion some extract of Belladonna was smeared round the orbit of his affected eye.

The 13th inst., the conjunctival congestion was less, and confined to the inner side of the membrane, there was less opacity of the cornea, and greatly diminished vascularity of the sclerotic; the pupil was more dilated; the tongue was clean; pulse 65, regular; his throat was rather inflamed-looking; he appeared in excellent spirits; had a good appetite, and was now, as recommended, taking two bottles of porter in the day; ordered a cathartic pill to relieve constipation.

On the 14th inst. the inflammatory action of the membranes was rapidly decreasing, the sclerotic vascularity remained round the margin of the cornea, but the colour of the vessels was much lighter; the cornea itself had begun to regain its transparency, the pupil was large, his general health and spirits kept good, his bowels had been freely moved, and his throat seemed better: he now stated he could discern light and shade with the diseased eye.

On the 16th inst. the improvement in the eye was marvellous: the cornea was almost quite clear again, the pupil was widely dilated, the redness of the conjunctiva was very slight and confined to the neighbourhood of the inner canthus; the radiating vessels of the sclerotic were still visible, but less distinct; his health and spirits continued excellent, he had a keen appetite, his tongue was clean, and his throat much better.

On the 17th inst. the improvement developed in the eye within the space of twenty-four hours was such that he could again distinguish objects; the opacity of the cornea had become absorbed, and it had almost returned to its normal state; a lingering inflammatory blush still remained in the sclerotic; the neighbourhood of the inner canthus seemed to have a little more redness than on the preceding day, but it appeared he had gone out into the cold air, and this may have accounted for the latter symptom.

On the 18th inst. he could see quite as well with his right eye as with the unaffected one, but the weakness which still remained prevented his looking at any object for more than a minute at a time. The sclerotic vessels still imparted a pink hue to the white of the eye; all conjunctival redness was gone. The blueish-white ring which encircled the cornea had greatly diminished. The bichloride of mercury was finished.

On the 19th inst. the cornea was quite transparent, but considerable vascularity remained in the sclerotic. His health kept good, and he had commenced to take cod liver oil. Did not renew the corrosive sublimate, of which he had taken, in all, two grains.

On the 21st inst. the eye was much stronger, and the sclerotic vascularity greatly lessened; the bowels had been freely moved. The cod liver oil seemed to agree with his stomach. The right tonsil was inflamed, and caused him some uneasiness in swallowing.

He was at his work the following day; he felt his eye getting stronger, and his throat better; he had applied a mustard and linseed poultice externally to it during the night, and received great relief from it.

On the 25th inst. every trace of inflammatory action had left, and the eye presented a normal appearance. He could now see almost as well as ever he had done. His throat being still a little troublesome, was cauterized with a strong solution of nitrate of silver. He kept in excellent health, and found the cod liver oil agreed well with him, as did the tincture of perchloride of iron, of which he was now taking fifteen drops three times daily.

The next day his throat, though better, was again cauterized. His eye was being strengthened by douches of cold water applied night and morning.

On the 28th inst. his throat was cauterized, and appeared greatly improved. He did not find any injurious effects from being at his work.

On the 30th instant his throat was much improved, and he could swallow without pain. I recommended him a mixture of chlorate of potass and tr. of steel, with infus. of quassia. I now considered him free from the malady for which he originally came to me, and discontinued my visits, believing the throat affection to be due merely to simple congestion of the mucous tract.

In reviewing the history of the case, some peculiarities may be observed, while the treatment adopted is perhaps deserving of a little consideration.

Mr. Henry Lee has described four varieties of chancre—viz., the Hunterian or true, the non-indurated or soft, the phagedænic, and the gangrenous or sloughing chancre; the third is most like the form presented in the foregoing report, but yet materially different. Mr. Lee in speaking of it says—"It produces suppuration, generally of one inguinal gland only, which yields an inoculable secretion. It is not followed by constitutional syphilis, and may be treated by local means."

In this patient it has been seen that one inguinal gland only suppurated, but that constitutional symptoms ensued, and these—neither preceded nor accompanied by any eruption of the skin—were confined to the right side of the body, and supervened on the healing of the primary sore; that there was no induration, and the chancre exhibited the process of ulcerative inflammation (*vide* "A System of Surgery," edited by T. Holmes, M.A., &c., vol. i., p. 461). It was seen that the right tonsil and uvula were congested and swollen, while no ulcers could be detected on any portion of the mucous membrane of the mouth or throat. These facts, together with the nature and course of the diseases which attacked the eye, do, I think, give an uncommon aspect to the whole case.

As noticed, the treatment pursued was successful, and throughout unattended by pyalism, or other indications of mercurialization, which were carefully watched for, in order that the use of mercury might be suspended or stopped should such arise. From the first, the strength was supported by a nourishing diet, and the irritation allayed by full doses of Dover's powder. A small amount of Plummer's pill was administered at the early stage, but merely with the object of acting on the skin, liver, and bowels, not as a prophylactic. The cauterization with strong nitric acid, and the subsequent local applications, having been attended by good results, and unaccompanied by any considerable amount of inflammation or constitutional disturbance, give sufficient evidence in their own favour. When the eye affections became apparent and the mercurial treatment was indicated, a mixture containing corrosive sublimate, in combination with henbane, colchicum, and ipecacuanha, as already observed, was adopted, the blood being at the same time strengthened by tincture of steel, in large and frequent doses, and this supplemented by cod-liver oil. The speedy resolution of the inflamed membranes, and the improvement which took place in the general health, may be spoken of as consequent on the treatment to which the system was subjected.

#### CASE OF FEBRIS NIGRA—"BLACK DEATH."

By JOHN RIDLEY, M.D., F.R.C.S.I., &c.

ON the morning of the 21st March I was called on to visit G. B., aged 17 years, an apprentice in a large grocery establishment. He had been in good health up to nine o'clock on previous evening, when he complained of rigors and headache. Supposing it was an ordinary cold, his feet were bathed in hot water, and he got a hot drink going to bed. At seven o'clock next morning a person going into his room observed him to be very pale and weak-looking, and he could not for some time speak, but after a little time he was able to say that he felt as if he was "smothering" in the night, but felt so weak he could not call any one. On my seeing him at eight o'clock, he was still very pale;

pulse 120, very feeble and indistinct; the sounds of the heart were quick, and striking the side with force; no bruit; respiration a little hurried—22 in the minute; no mucous or other rales; surface of the body cold; conjunctivæ congested; is perfectly conscious; says he has no headache now; has not vomited or been purged; presents the appearance of one who has received a shock.

Ether Chloric,

Spt. ammoniæ aromat., aa. gutt. 20.

to be given alternately with an ounce of wine every hour; heat to be applied to extremities.

Eleven o'clock.—Small dark spots have appeared over the face, the size of grains of shot; also on the feet and legs; pulse more feeble; heart's action weaker, and has lost its forcible beat; heat of body improved; tongue furred and swollen.

Wine to be increased to 2 oz.

Ether and ammonia drops to 30.

Beef-tea for drink.

Two o'clock.—Since last visit the black spots on the face have become larger—now appearing to be the size of a sixpence each. The nose and lips tumefied and livid. The spots on legs have also become larger, and those on the toes have extended to the soles of the feet; pulse very indistinct, and not to be counted; heart's action scarcely audible; no urine secreted since the attack; bowels acted once largely, discharge of the ordinary yellow character.

Four oz. wine, and  $\frac{1}{2}$  oz. brandy alternately every hour.

Acid hydrochloric,

Tinct. perchlor. ferri aa. gutt. 20,

Secunda hora emp. ves. cordis regione.

Half-past six o'clock.—Face now presents the appearance of a livid mask; great jactitation; pulse same as last report; breathing more hurried; eyes much congested; nose and lips more tumefied and livid; is perfectly conscious; asks questions relative to his family; spots on legs and thighs have now become large patches; urine still suppressed; a few scattered spots only on the body; bowels have acted again.

Enema amyli c. tinct. opii to be given, and repeated if purging goes on.

Wine and brandy to be continued.

March 22nd, half-past two o'clock, a.m.—Had some vomiting for the first time, followed by a convulsive movement of his head and arms, when effusion of mucus into bronchi took place and he died—in twenty-nine and a-half hours after first illness—and being conscious up to an hour before death.

The body after death presented the following appearance: Face and head much swollen, particularly the nose and lips, and covered with a large black patch, which extended from the malar bones to the chin, and across the face; dark patches down the front of the neck, also down the arms, which are of a dusky hue; hands livid and spasmodically contracted. A few scattered spots on the body, the thighs and legs covered with large black patches, the toes perfectly black, and the black appearance extends down the soles of the feet to the heels.

This case, in the treatment of which I was assisted by Dr. Moorhead, closely resembles those reported by Dr. Lyons in THE MEDICAL PRESS AND CIRCULAR for May 16th and June 13th of last year, and well described by him as "examples of extreme typhic prostration, with the associated condition of rapidly developed purpura hemorrhagica affecting the cutaneous system of capillaries."

It is to this affection the name of "black death" has been given, from its supposed similarity to the black death of the sixteenth century. Whether it is the same disease revived or not, it is no misnomer to call it so, from the rapidity of its course, the repulsive form it presents, and the eminently fatal character it assumes almost from the first symptom.

There are but five other cases, as far as I know, reported as having occurred in this country, four by Dr. Lyons, and one by Dr. Little, others are said to have occurred since, reports of which should be given, that the profession may have the fullest information of the history and progress of this most fatal disease.

### THE TREATMENT OF EPILEPSY: PRINCIPLES AND PRACTICE.\*

By JOHN CHAPMAN, M.D., M.R.C.P., &c.

(Continued from page 290.)

AFTER watching Dr. Radcliffe's theoretical summersaults, during the dizzy whirl of which he saw, for the first time, the nervous and muscular systems in a functional relation to each other precisely inverse to that which they are usually supposed to sustain, I rejoice in being able to observe him walking once more on the firm ground of practice, arm-in-arm with Dr. Brown Séquard; for now, the theory of epilepsy propounded by that eminent physician, the teachings of Dr. Radcliffe's experience, and my own neuro-pathological and neuro-therapeutical discoveries all concur in pointing out that the scientific treatment of epilepsy must be sought in methods of exercising a sedative influence on the nervous centres presumed to be specially indicated in each case. All that we know of the physiological effects of bromide of potassium is in harmony with our experience of its efficacy in treatment of convulsive affections. I believe I shall not be contradicted when I say that of all known drugs this has been proved to be the most successful in the treatment of the disease in question (of course I am here speaking of epilepsy of the kind often called idiopathic, or, in other words, of that form of the disease which is not associated with any removable eccentric cause). There are, however, certain objections to the use of bromide of potassium. *First*, its influence on the nervous system is of a degenerative kind: it lessens both the sensibility and the excito-moto power, and its influence on the brain being of essentially the same nature as that which it exerts on the spinal cord, its continued use in large doses, and, in some cases, doses adequate to restrain the epileptic attacks, may seriously impair both the intellectual and emotional nature. Though I have never seen the grave results of its copious administration described by M. Huet—viz., delirium, resembling the incoherence of idiotcy, mingled with hallucinations, I have, in two cases, seen impairment of the cerebral functions to the extent best denoted by the word stupidity, brought on by the protracted use of this drug in doses not considered large. The *second* objection to bromide of potassium is not a special one, for it may be urged against internal medicines generally—viz., that it operates on the whole system at once, and thus, so far as the nervous system is concerned, while exercising a sedative influence on those particular nervous centres, which, in any given case of epilepsy, are in a state of undue excitability, and is thus acting beneficially, it also exerts a like sedative influence upon the healthy parts of the nervous system, and lessens the nourishment of the brain. In cases where there is a tendency to cerebral congestion, the latter result will not be injurious; but in the majority of cases of epilepsy there is no such tendency, except during, and immediately after, the fits. I apprehend that bromide of potassium fails most signally as a remedy for epilepsy in those cases in which the tendency to cerebral anemia is most marked. The *third* and most decisive objection to this drug, when mainly relied upon, is that, though it often lessens the number of fits, and sometimes prevents their recurrence, it generally fails to cure the disease. I believe I am correct in stating that every one of the cases which I have treated successfully by means of the spinal ice-bag, had been previously treated unsuccessfully by means of bromide of potassium.

Believing, as I do, that the proximate cause of epilepsy

is seated in some part of the automatic nervous centres comprising the sympathetic ganglia, and what Dr. Marshall Hall calls the "true spinal cord," and that it consists in a state of excessive irritability or excitability of the parts, morbidly affected, associated with hyperæmia of those parts, I am of opinion that the therapeutical desideratum is one which may enable us to exert a sedative influence on those nervous centres morbidly affected, and on them alone. Now, in my opinion, this desideratum is supplied by the spinal ice-bag more completely than by any other means at present available for the treatment of the disease. This bag, which is made of various sizes, in order to be adapted to different patients, consists of several cells, so constructed as to allow of the application of the ice to the whole, or to special segments of the spine, accordingly as the physician may desire.\* When using it for the treatment of the disease in question, my method of applying it differs in different cases, and is determined by what I conceive to be the special requirements of each case, and, particularly, by the opinion which I may have formed as to the segments of the spinal cord and sympathetic ganglia, in which the proximate cause of the disease is chiefly seated.

Although I have distinctly asserted that the spinal and sympathetic nervous centres may be directly and powerfully influenced by modifying the temperature of the spinal region, it is probable that those physicians, who now for the first time hear of my method of treating convulsive affections will receive with incredulity my announcement that the nervous centres in question can be influenced by heat or cold—of such temperatures as are practically available—applied along the back, and that those affections may be treated most successfully by that method. Indeed, experiments have been made, the results of which have been alleged to be fatal to both my doctrines and practice. For example, Dr. Hughlings Jackson applied ice to the upper part of the spine, and then, while the ice was thus applied, observed the retinal arteries with the ophthalmoscope, and being unable to discern any enlargement of them, concluded that they, as well as the cerebral circulation, were in no degree influenced by the ice. Again, Dr. William Ogle has informed me that he has applied a hot poultice to the spine, and failed to observe any appreciable fall of temperature in the hands of the person thus experimented on. Now, I have a few remarks to make on these experiments, and the conclusions drawn from them. First, in healthy persons—and I understand these experiments were made on such persons—the arteries in all parts of the body are of normal diameter, and therefore the extent to which they may be dilated beyond their normal volume is comparatively small, and whatever increase or decrease of their diameters may be effected by modifying the temperature of the spinal region will, in many cases, be difficult of detection. If, on the other hand, arteries already much contracted be operated upon through the agency of the nervous system, the result will become strikingly apparent. But even in this case the experiment must be continued, not during an hour merely, but for a certain number of hours, during days, and perhaps weeks, though patients differ extremely in respect to the time required by their chronically contracted arteries to attain their normal volume. It appears to me that it might be expected, *a priori*, that when arteries have long been in a condition of tonic spasm, and indeed of partial atrophy, and when the starving structures which they supply have so far lost their vitality as to be no longer able, by virtue of the powerful elective affinity of their elements, to make those copious draughts on the

\* The spinal ice-bags are made of the following lengths:—8, 10, 12, 14, 16, 18, 20, 22, 24, and 26 inches. They vary in breadth from two to four inches and a quarter, the shortest bag being the narrowest, and the longest the broadest. The smallest sizes, or those 8, 10, and 12 inches long, are, in respect both to length and breadth, suitable for children; those 14, 16, and 18 inches long, for youths of both sexes; those 20 and 22 inches long, for women; and those 24 and 26 inches long, for men. Of course there are cases in which a tall woman may need a bag 24 inches long; while one 22 inches long will be suitable for a very short man. The bags may be procured in London from C. Mackintosh and Co., the manufacturers, 83, Cannon-street, E.C.; S. Maw and Son, 11, Aldersgate-street, E.C.; John G. Gould, 193, Oxford-street, W.; and in Glasgow from Thomas Chapman, 56, Buchanan-street; also, by order, from all druggists.

blood passing through those arteries, which in health they were wont to do, a considerable time must elapse, even after all extra normal stimulus to these vessels from the nervous system has been cut off, before they can regain their full healthy calibre, and before the structures to which they are distributed can again acquire adequate nourishment. And, as just said, experience confirms this expectation.

In the introduction to my work "On Cholera" I have given evidence that the activity of every gland, and gland follicle in the body, is produced by stimulus transmitted to it from the cerebro-spinal system; and that the function of the sympathetic, in so far as glands are concerned, is the same as that which it performs in relation to all other structures—viz., that of presiding over the action of the arteries supplying them. Each gland is thus subject to two opposing forces, one transmitted through a cerebro-spinal nerve, causing the gland to function and to draw blood to itself through its appropriate artery, the other transmitted through a sympathetic nerve, and causing the artery on which it is ramified to contract with a degree of energy proportionate to the amount of stimulus which it receives. I have also adduced reasons for believing that this two-fold relation of the nervous system obtains with respect not only to glands, but to every other part of the body, so that we may say of the bodily structures generally, "that, in addition to the sensory nerve supplied to each, there are two motors: one exercising on the cellular constituents of the structure a stimulant influence, causing it to attract blood to itself; the other by stimulating the muscular coat of the arteries, causing them to contract, and thus to regulate, restrain, or even to arrest the blood-supply." If this doctrine be true, it is obvious that the effects of cold or heat applied along the spine will only become most strikingly apparent in cases of disease, or in other words, when there is any considerable perturbation of the action of the forces in question, the one dominating over the other to an abnormal degree. This consideration affords, as it appears to me, an important additional explanation why it is that the effects on the peripheral circulation of cold or heat applied along the spine of healthy persons, are less perceptible than those inducible in cases of disease. Moreover, in as much as it is fairly presumable that, in different individuals the relative strength of the cerebro-spinal and sympathetic nervous systems is aboriginally different, this same consideration explains why it is that in different individuals widely different effects are produced by modifying the temperature of the spinal region.

Without further discussion of physiological or theoretical views I will now cite some positive evidence that the therapeutical method in question is peculiarly adapted for the successful treatment of convulsive affections. I need scarcely point out how desirable it is to obtain a power of influencing the cerebral circulation, and it will, I presume, be admitted, that if evidence can be tendered that any branch of the internal carotid artery can be influenced in the manner I advocate, the conclusion is inevitable that the cerebral circulation generally can be thus influenced. In the Introduction to my work on "Diarrhoea and Cholera" I said: "My own success in improving vision by spinal applications has been not less striking than novel; and Mr. Ernest Hart, complying with my request to make trial of the method I had originated, has already published a report of his successful treatment of a case of that hitherto incurable form of blindness, cerebral amaurosis, and has informed me of two other cases of grave impairment of sight, in which, by the use of spine-bags, he has conferred signal benefit. In the case of amaurosis, consisting of spasmodic contraction of the retinal arteries, they became dilated by means of ice—the retina losing its pale anæmic colour and resuming the pinky hue of health, the vision was correspondingly improved, and, simultaneously, the epileptic attacks, from which the patient had long suffered about three times a-week, were so subdued that they occurred only twice during the whole five weeks of treatment. In one of the other cases, in which there was congestion of the retinal vessels, causing intermittent

amaurosis, the symptoms, which had long withstood all ordinary treatment, were completely subdued by means of heat to the spine." In two cases, to be presently mentioned, of great cerebral anæmia resulting in extreme prostration, and frequent fainting fits of long duration, a complete cure has been effected after all other methods have failed. I could mention many cases occurring in my own practice, in which I have obtained evidence that the cerebral circulation may be influenced in the manner described, but the foregoing facts will probably suffice to produce conviction of this truth. When it is considered that *le petit mal*, and the initial stage of *le grand mal* of epilepsy, consist of spasmodic contractions of the cerebral arteries, and that, in the intervals of the attacks, there are often sudden contractions like in kind but less in degree, and therefore not resulting in the abolition of consciousness; and, moreover, that all these abnormal contractions are due to excessive irritability of the nervous segments in the upper dorsal and lower cervical regions, it is plain that a remedy which will act as described must be of immense value in cases of epilepsy.

It is well known to all who see much of this disease, that in the intervals of the attacks the respiratory functions are often more or less impaired and irregular, sighing respiration, and occasionally a slight suffocation, being perhaps the most usual symptoms, and denoting inadequate movement of blood through the lungs, or more or less pulmonary congestion. In innumerable instances I have seen the pulmonary circulation most decisively influenced by the applications of cold and heat between the scapulae, and may cite the evidence of Professor Bencke, published in the *Archiv für wissenschaftliche Heilkunde*, in proof that pulmonary hemorrhage occurring in an advanced case of phthisis was rapidly and completely arrested by the application of two columns of heat, one on each side of the dorsal spine.

A frequent accompaniment of epilepsy, as well as of other disorders of the nervous system, is a tendency to sickness. I have not ascertained what proportion of the whole of the epileptics which have come under my care have been troubled with nausea or vomiting, but a considerable number have complained of these symptoms. Now, I believe I am justified in saying that the more experience physicians have of the treatment of these symptoms, the more readily they will recognise the great difficulty, and not seldom the impossibility of arresting nausea and vomiting of this kind by drugs. On the other hand I can state positively, from an extensive experience, that few diseases are more completely under control than are nausea and vomiting, if treated properly by means of the spinal ice-bag.

Among the chronic ailments to which epileptics are peculiarly liable, none, perhaps, is more troublesome and more intractable than habitual constipation, which, as a general rule, though temporarily relieved, is permanently increased by the frequent use of purgative medicines. This form of constipation is, in my opinion, due not to any lack, but to a superabundance of nervous energy transmitted to the bowels; the arteries supplying them are spasmodically restricted, and therefore convey an insufficient quantity of blood; the muscular coat of the intestines ceases to be adequately nourished, becomes more or less atrophied, and so losing more or less its contractile force, its vermicular and expulsive activity is impaired, and constipation is the result. In such cases, ice along the appropriate part of the spine, ought, according to my theory, to remedy this condition, and I can affirm with the utmost confidence, derived from experience in the treatment of a large number of cases, that in almost every instance it does so. When it is borne in mind the part played by large accumulations of feces in the bowels in irritating the spinal and sympathetic centres, and thus inducing epileptic attacks, it will be conceded that it is difficult to overestimate the importance of restoring the healthy function of the bowels, and the value of any remedy which will do so.

Functional disorders of the womb are peculiarly condu-

cive to epileptic attacks in those already predisposed to them, and are an adequate cause of them in other cases. In my pamphlet on the "Functional Diseases of Women," I have given a considerable number of cases, proving that menstruation may be induced and increased by the application of ice along the lower third of the spine, and conversely, that menorrhagia may be controlled and cured by the proper application of heat in the same region. I also possess evidence that leucorrhœa as well as certain grave affections of the male genito-urinary organs may be no less beneficially influenced in like manner. And finally, as I have already stated, when referring to Dr. Radcliffe's theories, the fact is now indisputably established, that almost every case of habitual coldness of the feet may be completely cured by the use of the spinal ice-bag.

It will, I am sure, be admitted that if these statements are true, they justify the strongest expectation that the therapeutical method in question, when applied in the treatment of epilepsy, is likely to be attended with an unusually large measure of success. This expectation has been so far justified by experience, that though, in common with every physician, I have been obliged not unfrequently to deplore failures, I can appeal to a considerable number of cases of epilepsy which I have cured, and to many others in which the benefit, both spinal and constitutional, has been so great as to justify a hope of cure should the treatment be persisted in.

Several of the cases in question exemplify in an extraordinary degree the efficacy of the therapeutical method which I have adopted. In these cases, the fits, which as will be seen by the following summary of them, ceased so speedily after its first application, that its power seemed almost magical:—

H. M. suffered from little fits, occurring generally about twice a day. I began to treat her February 24th, 1863: at the end of a fortnight the attacks quite ceased, and up to April 24th, 1865, when I last saw the patient, had never recurred.

C. J., male, had violent convulsive fits, recurring, on an average, his wife said, three times a day. I began to treat him May 16th, 1863: the fits ceased from that day until August of the same year, when he had one. Up to March, 1864, when I last heard from him, he had not had another.

S. G., male, suffered from little fits, each consisting of a period of unconsciousness preluded by a shriek. They recurred about a dozen times a day. I began to treat him June 10th, 1863: on the following day he had four fits, each, however, being unaccompanied by a shriek; and since then he has never had another.

Miss D. had convulsive fits, recurring several times a month. My treatment of her began January 10th, 1864: she had one attack during a week when treatment was omitted, and none afterwards up to July 9th, 1864, the last date at which I heard of her.

H. C., female, had convulsive fits about three times a month. She came under my care November 24th, 1864: she had two fits in January, 1865; and since that date she has not had one.

K. E., female, had violent convulsive fits, from twelve to twenty a month. She was first seen by me December 9th, 1865: during the first two months of treatment she had five fits; since that time she has had none.

S. T. J., male, had convulsive fits, varying in number from about six to ten a month. I began to treat him November 16th, 1865: he had one fit in January, 1866, and has had none since.

F. A., male, suffered from falling fits, occurring about once a week, from "swooning," which occurred many times a week, and very frequently from giddiness. He consulted me for the first time February 12th, 1866: up to April 23rd, when I last saw him, he had not had one falling fit, and the swooning and giddiness had quite ceased.

Mrs. A., suffered from fainting-fits of long duration and carrying frequency, with excessive coldness of the surface of the body during the attacks, five or six of which occurred during the ten days previous to coming under my

treatment, which began August 24th, 1864: she had one fit during the first week of treatment, but afterwards never had another.

Mrs. C., a patient in King's College Hospital, under the care of Dr. Playfair, suffered from fainting-fits occurring about eight times a week, sometimes oftener, and sometimes lasting an hour at a time. Dr. Playfair treated her by bromide of potassium and valerianate of zinc successively; but the fits continued as bad as ever. The spinal ice-bag was then applied—December 22nd, 1865: during the first week of its use she had only three fits, but afterwards, up to the last date of the report which Dr. Playfair kindly gave me, she had no further attack.

H. R., male, five months old, first seen by me July 13th, 1863. Had had fifteen attacks of convulsions during the previous month, five of which had occurred during the previous two days. There was great cerebral congestion, and the child having been treated vigorously by means of calomel, and blisters to the back of the head, was given up as a hopeless case by the medical attendant. By the use of the spinal ice-bag, the child was instantly soothed, and was soon completely recovered: he has never been convulsed since. He has been under my care at times subsequently on account of other disorders of the nervous system, from which he was quickly relieved; and only a few days ago he was reported to me by his father as being quite well.

I could adduce a considerable amount of additional evidence in proof of the astonishingly great therapeutical potency of the spinal ice-bag in treating the convulsive affections of children; and when it is borne in mind that in England every year about 24,000 children under five years of age are destroyed by convulsions alone, and that in a large proportion of cases the epileptoid diseases of adults originate in the convulsions of infancy, the value and importance of the method of treatment in question can scarcely be over-estimated.

As yet I have had no experience in the treatment of puerperal convulsions by means of ice: the practice has already, however, the sanction of the great authority of Dr. Todd, who testified to its efficacy; and I venture to close this paper with the prediction, that the judicious application of the spinal ice-bag will be found to exert over that appalling and not seldom fatal malady a controlling and remedial power, far surpassing that of all other means hitherto used for subduing the disease.

Dr. CAMPS said that the elaborate and admirable paper to which they had just listened was so comprehensive, and contained such a large amount of matter, that it was impossible for him to recall it all and bear it in mind, in order to offer any adequate comments upon it. He said he should only advert to two or three points. If he understood Dr. Chapman rightly, that the seat of the proximate cause of epilepsy might be located, in certain cases, in the lower parts of the spinal cord, he could not concur with him, for he was satisfied that the pneumo-gastric nerves must be morbidly excited as one of the conditions of an epileptic fit, and of course this implies that the medulla oblongata is involved. He quite agreed with Dr. Chapman in the opinion that Dr. Radcliffe's theory of muscular motion, as well as his pathology of convulsive affections, is unscientific and untenable; indeed he believed that no physician accepted his theories. He thought Dr. Chapman's paper so important, and so deserving of careful attention, that he hoped it would soon be printed, so as to be generally accessible, and suggested that Dr. Chapman should facilitate the discussion of the subject, by communicating to the Society an additional paper upon it before the close of the present session.

Dr. ROUTH could not refrain from adding his testimony to the great importance of the subject which Dr. Chapman had brought before them that evening. He said he had been to some extent a pupil of Dr. Chapman's, and had witnessed his treatment of certain cases at the Samaritan Hospital. The result was the production of certainty in his mind of the truth of Dr. Chapman's doctrine—viz., that the

circulation and nutrition of remote parts, or of the periphery of the body, may be increased by the application of ice along the spine, and may be decreased by the application of heat to the same region; also, that the functional activity of the spinal cord may be depressed or exalted in the same way. These facts, he repeated emphatically, are thoroughly established and indisputable. Being so, they opened up the prospect of a great therapeutical revolution. Every one must see this who bears in mind the very large proportion of diseases which may be treated most successfully by increasing or decreasing the circulation and nutrition of the parts morbidly affected; indeed, he did not hesitate to express his belief that even cancer might be beneficially treated by this method, and was confident that surgeons might derive great aid from it in various cases coming under their cognizance, especially when atrophy or hypertrophy was a leading symptom. In confirmation of his statements, he said the method had been tried in a case of what he called "convulsive action of the stomach," associated with pregnancy. The patient suffered from sickness continually for nearly three months; it was no use giving her drugs, for they came up again directly. She had been supported to some extent by injections per anum, but was in such a state of exhaustion that the question of inducing abortion, in order to stop the sickness, was entertained. By Dr. Chapman's advice the spinal ice-bag was applied: the immediate effect was the production of refreshing sleep; by continuance of the treatment the sickness steadily and completely subsided, and the patient is now well and gaining flesh. Dr. Routh said he had tried the method in a case of profuse menorrhagia: after the double columned hot-water bag had been applied during an hour, the flow ceased. He had also tested the principle in cases of infantile convulsions. In one case the child had twelve convulsions in one day, and, of course, under ordinary circumstances, could not, he said, be expected to recover: the convulsions ceased as soon as the spine bag was applied, have never recurred, and the child is now quite well.

The time having now arrived for closing the debate, Mr. Dunn moved, and Dr. Camps seconded the motion, that the discussion be prolonged for a quarter of an hour. The motion being carried, Mr. Dunn inquired of Dr. Chapman what effect is produced on the circulation; whether the pulse is increased in volume or not, by the application of the spinal ice-bag.

Dr. SANSUM expressed the opinion that Dr. Radcliffe's theory is probably correct, or at least that numerous facts seem to countenance it. He observed that the rational treatment of epilepsy is very far from being comprised, as he understood Dr. Chapman to allege, in the treatment of the paroxysms; and that their provoking cause must be removed.

Dr. BROADBENT did not think Dr. Chapman's theory of epilepsy an adequate one, and observed that the cases of cure which he had cited are cases in which the fits have been numerous, or cases of fainting-fits, and had not stated how long the disease had lasted in each case; that cases in which the fits are very numerous yield more easily to treatment than those in which the fits recur at more distant intervals. He testified to the great efficacy of bromide of potassium as a remedy for epilepsy, and said that he had never seen its use result in mental impairment.

Dr. ROGERS expressed his sense of the great value of the paper which they had heard, and expressed a hope that Dr. Chapman would take an early opportunity of again bringing the subject of it before the members of the Society. While greatly interested in and disposed to accept Dr. Chapman's views, he wanted more facts in evidence of them, and must for the present regard them as *sub judice*, and maintain an attitude of reserve. He had, however, he said, nothing to allege against them, and hoped that further experience of their application would finally prove them true. His own experience tended in that direction. One of his children had convulsions during thirty-six hours; ice applied to the spine completely stopped the fits. And, quite recently, in two cases under his care, of whooping-

cough followed by convulsions, the convulsions ceased to recur after the spinal ice-bag was applied.

The PRESIDENT, when about to call upon Dr. Chapman to reply, gave particulars of a severe case of epilepsy, in which the use of bromide of potassium had suspended the fits.

Dr. EDMONDS asked permission to move the further prolongation of the debate. The motion having been acceded to, he said he felt a peculiar interest in the subject, in consequence of having lost a child by laryngismus stridulus. He mentioned the interesting fact that it was the constant practice of the late Mr. Gossett, well known in the neighbourhood of Old Broad-street, City, to prescribe in cases of infantile convulsions an ice-pillow, the ice being applied in a bladder to the occiput and nape of the neck. Dr. Edmonds also mentioned a case of tetanus, particulars of which he has published, in which he applied ice in an ox-gullet along the spine, and rescued the patient from seemingly impendent death. She had been previously treated by two other medical men in the course of the eighteen hours during which the disease had been progressing, but without benefit. Her arms were firmly flexed, the hands being drawn together near the chin; the muscles were hard and rigid, and the woman was screaming in agonies of pain. Within half an hour after the ice was applied, she was wonderfully relieved, and very soon completely recovered.

Dr. CHAPMAN, in the course of his reply, said he thought the difference between Dr. Camps and himself as to the parts of the nervous system primarily implicated in the production of an epileptic paroxysm, was rather one of words than substance. Dr. Chapman said he believed that epilepsy may be induced by a morbid state of the spinal cord as low down even as the lower third; but that when such is the case the irritation must be propagated upwards from the primary seat of the disease, as far at least as the level of those ganglia of the sympathetic which control the cerebral arteries, and that unconsciousness, the first stage of an epileptic fit, may be induced by irritation of those ganglia without any primary co-operation from the medulla oblongata, through the medium, as Dr. Camps alleges, of the vagi; of course, as soon as the brain has abdicated its functions as the co-ordinating power, the whole spinal cord, together with the medulla oblongata, acts automatically, in a tumultuous, chaotic, and aimless way, and thus constitutes the convulsive paroxysm. Replying to Mr. Dunn, Dr. Chapman said, that as a general rule, ice applied along the spine increases the peripheral circulation, and that heat so applied lessens it; that in the preface to his pamphlet on the "Functional Diseases of Women," he gave particulars of two cases, one of which was treated at St. Thomas's Hospital, the other at Guy's, in evidence of the truth of this proposition. He mentioned a case of intense hyperæmic headache, with hot dry skin, and pulse at 120, recently under his care, in which the application of the spinal hot-water-bag made the head cool, caused sweat to break out on the arms and hands, the pulse to fall to 80, and the pain in the head to cease entirely within half an hour from the time when the bag was first applied between the shoulders. He said that the susceptibility of patients to the influence of heat or cold applied to the spine differs extremely in different cases, and explained what he conceived to be the reasons of these differences. Adverting to Dr. Sansum's remarks, he explained that so far from his treatment of epilepsy being restricted to treating the paroxysm, he rarely treated it at all, but aimed, after removing the exciting cause, if any such were found removable, to exercise such an influence on the nervous system during the intervals of the fits as was most likely to prevent their recurrence. In reply to Dr. Broadbent, he said that some of the cases of cure of epilepsy which he had cited were cases in which the fits were not extremely numerous; for example, in three cases they recurred only three or four times a month; in several cases they had been of several years' continuance. He quite concurred in the general opinion of the meeting that bromide of potas-

sium, when given in moderate doses, does not usually produce the stupefying effects which, in some cases, are consequences of its use; the objection which he urged to it on this ground was based on his experience of it in two cases, in which the mind had been markedly impaired by doses not larger than are commonly given. Dr. Chapman closed his remarks by thanking the gentlemen present for the attention with which they had listened to his paper, and the great interest which they had evinced in the subject he had brought before them.

## Lectures.

### CLINICAL LECTURES

DELIVERED IN

STEEVENS' HOSPITAL,

TOGETHER WITH

OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,

PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,

PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

OBSERVATIONS ON THE HEMORRHAGES.

(Continued from page 295.)

To another source of sanguineous exudation, nearly akin to that to which allusion has just been made, we must devote a brief consideration. During the progress of protracted chronic organic disease, the whole circulating mass undergoes a slow, gradual, progressive change, which ultimately gives rise both to hemorrhage and dropsy. During the long course of these diseases, the digestive and respiratory functions are impaired. The blood, imperceptibly, is altered, and the enfeebled exhalents allow either coloured or uncoloured blood to escape; the former usually from mucous surfaces, the latter either into the meshes of the areolar tissue, or into the serous cavities, or, as frequently happens, into both. The diarrhoeas and profuse perspirations, which often characterize such cases, are referable to the same cause.

A case or two will best illustrate the subject. An officer returned to this country in broken-down health; he had suffered for many months from frequently recurring attacks of intermitting fever. The fever and ague were caused by the malaria of Hong Kong. His liver was considerably and permanently enlarged, the spleen enormously hypertrophied; he was much atrophied; but the paroxysms of ague had ceased. Soon the ankles became cedematous, and blood trickled almost constantly from the nose, and, curiously enough, it happened here, as in a few other cases of this nature which I have witnessed in which there was great enlargement of the spleen, the blood flowed exclusively from the left nostril. The trickling of blood from the left nostril continued for many days; it ceased; he became universally dropsical. He lingered on for a long while in a hopeless condition. During the whole lengthened course of the disease he was unable to receive and digest a sufficient quantity of food (even of the lowest quality) to create a normal supply of blood. Such is the epistaxis so often symptomatic of diseased liver and spleen.

A labouring man, suffering from the effects of tuberculated liver, caused by habitual imbibition of alcohol in large quantities, was suddenly attacked with melæna. Blood was vomited, and descended through the intestinal tube to an enormous amount. He was brought to the threshold of the grave; he could neither speak nor move; for hours he was pulseless; he remained and continued to be deadly pale. There was no second attack of hemorrhage, but a dropsical effusion soon after manifested itself. The effusion into the sac of the peritoneum was very great. He derived, more than once, temporary relief from tapping.

At first, the dropsy was not extended beyond the areolar membrane and cavity below the diaphragm. The upper and lower halves of the body presented a singular contrast; that above the diaphragm exceedingly attenuated; that below swollen out to a great size. Afterwards, as the structure of the blood became more and more impaired, the dropsy was universal. This man's liver presented the usual appearance of that which has been termed the whiskey liver.

About two years ago I attended a lady in her thirty-fourth year, in whom epistaxis, towards the close of the disease, appeared, at once difficult to control, and, in her exhausted state, fearfully debilitating. Before her marriage, she had laboured under chlorosis. Soon after her marriage (ten years previously), pleuritis, with great effusion, had nearly terminated her existence. The right side remained ever afterwards contracted. Her recovery, however, was so complete, that she became the mother of a fine child. About twelve months before her death, an abdominal moveable tumour caused her much uneasiness; this disappeared. She then suffered from uterine irritation, and lastly, enlargement of the liver. Ascites, and dropsical effusion confined to the lower extremities, with sometimes profuse perspirations, sometimes wasting diarrhoeas, were the prominent symptoms. About six weeks before the fatal termination of the disease, she bled periodically from both nostrils. The bleeding always took place early in the morning, on awakening from a short, broken, and disturbed sleep. The first bleeding was the most copious, and caused a sudden and great change in her whole aspect and appearance. The subsequent bleedings, which recurred daily at the same hour, were far less profuse, yet, to her, extremely debilitating. For ten days the epistaxis recurred regularly; it then became less frequent and less regular, and, for at least a fortnight before her death, wholly ceased. This patient was to the utmost possible degree attenuated. Thus was epistaxis co-existent with dropsy; and both the result of protracted chronic exhausting organic disease. Many, indeed, are the chronic diseases, which, either with or without specific fever, terminate in effusions of blood, both coloured and uncoloured.

Sometimes an altered and deteriorated condition of the blood, productive of epistaxis and other hemorrhages, is caused by the frequent and long continued introduction into the system of poisons, such as malaria, mercury, alcohol, tobacco, &c.

Not many days ago I saw, a case of a young man in whom purpura hemorrhagica, in its most fearful and fatal form, was produced solely by the habitual abuse of these poisons, particularly alcoholic. His family, by his death, sustained a great loss. His habits of life were suicidal.

A corresponding case, one in many respects resembling that reported at the commencement of this paper, fell under my observation about three years since. It was that of a young man who, influenced by injurious companionship and an almost unlimited command of newly-acquired wealth, plunged unrestrainedly into every species of sensual indulgence; habits of intoxication became so inveterate, that at no time of the day was he perfectly sober; rarely was he seen without a pipe or a cigar in his mouth; courses of mercury for the cure of syphilis succeeded each other in quick succession. For nearly three years this course of life, without any apparent detriment to health, was persisted in. In about a fortnight after he had been exposed to the infection of small-pox, he sickened; having for two days struggled against prostrating disease, he was compelled to succumb, and to remain in bed. He complained of little else than of (as he termed it) distressing lumbago. On the morning of the third day a rash was discovered; and after the lapse of some hours the exanthem exhibited the characters of the variolous eruption. Long before the vesicles approached maturation they not only ceased to fill, but so far subsided as in a great degree to lose their specific features. Livid and black were now the numerous petechial spots, of various sizes, with vibices and large ecchymoses, which unexpectedly appeared over the whole surface. It was remarkable how

abruptly this fatal change took place; till then the case presented no other characters than those of variola with fever. Soon, thin, dark blood began to trickle from the nares, from the angles of the mouth, and many mucous surfaces. The odour emanating from the whole surface was insufferable. Before death he was semi-putrid. On the fourth day from the appearance of the black petechiæ, he died. Thus it was that a previously poisoned blood rendered an accidental febrile disease speedily and inevitably fatal.

It is lamentable to think how many young men there are who run this mad career of excess, unaware of the fatal sword which is suspended over them. They fling away life, health, and real enjoyment, as an untutored savage discards a valuable mass of precious metal, and clutches a string of worthless but glittering baubles. Months, even years, may elapse without any warning of danger; an attack of some prevailing epidemic, or of inflammation or fever, comes unexpectedly upon them. The chances of recovery, the chances of triumphing over the disease are, to them who have so lived, an hundred-fold diminished. Such is the hemorrhagically fatal effect of the gradual and prolonged infusion into the system and blood of those substances which in habitual excess become slow but virulent poisons. I cannot readily forget the observation of a lady whose husband was dying of fever, to which, at an early period of the disease, the appearance of lurid petechiæ with utter prostration, gave an all but hopeless character. She had herself abandoned all hope, having been painfully cognizant of the ruinous career he had for years previously been running. Alluding to his hopeless state, she said: "He has squandered away a fine constitution, an exalted intellect, and a princely fortune; all these valuable gifts he has sacrificed on the altar of unrestrained sensuality: on his offspring he has entailed impaired constitutions and poverty."

Several years ago I witnessed a remarkable and fatal case of supervening purpura hemorrhagica. So slight were the symptoms, that the note in which Sir Philip Crampton was requested to see this gentleman was couched in language which did not lead him to suppose that aught in the slightest degree of import ailed; it had reference principally to some trivial and non-medical subject about which he wished to speak with Sir Philip Crampton. The note concluded by observing that, if he happened to pass that way, he would be glad to see him, as he did not feel himself quite well enough to call at Sir Philip's house. I mention this to show how slight the premonitory and existing symptoms at that time were. Certainly, one not well acquainted with the earlier characters of this fatal disease might easily be thrown off his guard. Sir Philip, however, did not fail to recognise its true nature and its danger, though at his first visit there was apparently little in the characters of the case to warrant any, even the slightest apprehension. He found him sitting up, and in the act of writing a note; he was advised to remain in bed. On the following day the prominent symptoms were, fever, a dusky red rash, generally diffused, soreness of the throat, singular prostration of strength, and severe pain in the lumbar region. After the lapse of a few hours the appearance of livid petechiæ, numerous vibices, large ecchymoses, particularly wherever pressure, even the slightest, happened to be applied, evinced but too certainly the rapidly fatal tendency of the disease. At the end of three days from the time when re-action was established, he expired. It was a remarkable fact that, having been cupped over the loins, back, ichorous blood never ceased to flow from the wounds inflicted by the scarificator, till he ceased to breathe. This gentleman held an official situation, which, for many hours daily, confined him to the desk. What the predisposing and exciting causes of a disease so malignant, so hurriedly fatal were in this case, I am unable to tell. Cases do occur which, in the present state of our knowledge, baffle all our efforts to throw a clear and satisfactory light upon their origin and causation.

## DUBLIN UNIVERSITY PROFESSORSHIPS.

A BILL entitled an Act to open the Professorships of Anatomy and Chirurgery, Chemistry and Botany, in the University of Dublin, to all Persons irrespective of their religious Creed; and to amend the Act 40 Geo. 3. (Ireland), Chapter Eighty-four.

WHEREAS under the provisions of an Act passed in the Parliament of Ireland in the Fortieth Year of the Reign of King George the Third, Chapter Eighty-four, the Professorships of the University of Dublin of Anatomy and Chirurgery, Chemistry and Botany, are now by Law limited to Protestants of all Nations.

And whereas it is expedient to remove the said Disability, and to open the said Professorships to all duly qualified Persons, and otherwise to amend the said Act:

Be it therefore enacted by the Queen's most Excellent Majesty, by and with the Advice and Consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the Authority of the same:

1. *Removal of Disabilities.*—That from and after the passing of this Act the said Professorships of Anatomy and Chirurgery, Chemistry and Botany, in the University of Dublin, shall be open to Persons of all Nations, and that Candidates for the said Professorships or for the Professorships on the Foundation of Sir Patrick Dun shall not be subject to any Disability on account of Religion, or Want of a Medical Degree from any University.

2. *Election of King's Professors.*—Sections Fifteen, Sixteen, and Seventeen of the said Act are hereby repealed, and in lieu thereof be it enacted, That the said King's Professors shall be elected by the President and Fellows of the King's and Queen's College of Physicians.

3. *Delivery of Clinical Lectures.*—From and after the passing of this Act the said University Professors of Chemistry and of Botany shall cease to deliver the Clinical Lectures required by the said Act of the Fortieth Year of King George the Third, and instead thereof such Lectures shall be delivered by the Professor of Surgery in Trinity College, and the University Anatomist: and the said Professor of Surgery and University Anatomist shall be respectively entitled to the Fees payable heretofore to the said University Professors of Chemistry and Botany: Provided always, that nothing herein contained shall affect the Rights of the present University Professor of Chemistry in the event of his electing to deliver such Lectures during his Tenure of such Professorship.

4. *Power to appoint a Clinical Lecturer.*—In case any of the King's Professors or University Professors, or the University Anatomist, shall neglect to attend the said Hospital, or deliver Clinical Lectures, as required by the said Act, it shall be lawful for the President and Fellows of the King and Queen's College of Physicians, in the Case of the King's Professors, and for the Provost (or in his Absence the Vice-Provost) and Senior Fellows of Trinity College, Dublin, in the Case of the University Professors and University Anatomist, to dispense with his delivering such Lectures; and in such Case it shall be lawful for the said President and Fellows of the said King and Queen's College of Physicians, and for the Provost (or in his Absence the Vice-Provost) and Senior Fellows of Trinity College, Dublin, respectively, to appoint a Physician or Surgeon to attend the said Hospital and deliver the Clinical Lectures in the Place of such Professor so neglecting to lecture; and the Physician or Surgeon so appointed shall be entitled to receive and be paid the Fees to which the Professor so neglecting to attend the said Hospital and deliver such Lectures would have been entitled.

5. *Power to make Regulations respecting Lectures.*—That the Thirty-first Section of the said Act be repealed, and in lieu thereof be it enacted, That it shall be lawful for the President and Fellows of the King and Queen's College of Physicians, in the Case of the King's Professors, and for the Provost (or in his Absence the Vice-Provost) and Senior Fellows of Trinity College, Dublin, in the Case

of the University Professors, each College with the Assent of the other to make Regulations respecting the Lectures to be given by its own Professors: Provided always, that if either the President and Fellows of the King and Queen's College of Physicians, or the Provost (or in his Absence the Vice-Provost) and Senior Fellows of Trinity College, shall refuse to agree to the Regulations proposed by the other College, in such Case the Regulations so proposed shall be submitted to the Visitors of the College which refuses to agree to them; and it shall be lawful for such Visitors, and they are hereby required, upon hearing such Reasons as may be offered on both Sides, to determine whether the Regulations submitted to them shall or shall not be adopted, and the Decision of such Visitors in any such Case shall be final and conclusive.

6. *Salary of Professor of Midwifery.*—And whereas by the Tenth Section of the said Act it is enacted, that after the Hospital therein mentioned should be completed, and after defraying the Charges arising from the Salaries and Expenses therein also mentioned, and the necessary Expenses of maintaining One hundred Patients, and the Establishment of such Hospital, which shall not be defrayed by private Contributions, then the clear annual Surplus of the Rents of the Estates therein mentioned shall be applied in the first place to support a Professor of Midwifery, who shall have a Salary of One hundred Pounds a Year, and no more: And whereas it is expedient to provide such Salary for a Professor of Midwifery irrespective of such Restriction: Be it enacted, That from and after the passing of this Act such Professor of Midwifery shall be entitled to receive and be paid the Salary of One hundred Pounds (late Irish Currency) per Annum out of the Rents of the said Estates; and that in consideration of such Salary the said Professor shall give Instruction in the Diseases peculiar to Females and in practical Midwifery in connexion with Sir P. Dun's Hospital; and that each Student availing himself of such Instruction shall pay to the Governors of the said Hospital the Sum of Three Guineas annually, to be applied by them to the Maintenance of Beds for the Treatment of Diseases peculiar to Females; and that each Student shall further pay to the Professor of Midwifery such Fees as shall be authorized by the Governors of the said Hospital, with Consent of the President and Fellows of the King and Queen's College of Physicians, and of the Provost and Senior Fellows of Trinity College.

7. *Management of Library.*—That Section Twelve of the said Act be and the same is hereby repealed: And whereas in addition to the Salary of the Librarian appointed under the Provisions of the said Act, being the Sum of Seventy Pounds (late Irish Currency), a Sum of Thirty Pounds per Annum has been for several Years applied to the Purchase of Books for a Library, and the Sum of Six Pounds Six Shillings to the Payment of a Library Porter: Be it enacted, That such Salary and Payments for the Purposes aforesaid shall continue to be made; and that it shall be lawful for the President and Fellows of the said King and Queen's College of Physicians to make such Rules and Regulations as to them shall seem necessary and proper for regulating the Duties of such Librarian, the Purchase of Books, and the Management of the said Library.

8. *Vacating of Fellowships.*—Whereas by the Forty-first Section of the said Act it is enacted that every Fellow of the said College who should thereafter accept any of the said Professorships should by such Acceptance immediately vacate his Fellowship in the said College of Physicians, and it is expedient that such Provision shall be repealed: Be it therefore enacted, That after the passing of this Act the accepting of any of the said Professorships by a Fellow of the said College shall not vacate his Fellowship; and that the present Professors, who on accepting their Professorships vacated their Fellowships, shall be and are hereby restored to their Fellowships in the said College, and all the Rights and Privileges thereunto belonging.

9. *Short Title.*—This Act may be cited for all Purposes as "The School of Physic (Ireland) Amendment Act, 1867."

## Review.

PHYSIOLOGICAL REMARKS UPON THE CAUSES OF CONSUMPTION. By VALENTINE DUKE, M.D., Fellow of the Royal College of Surgeons, Ireland; Licentiate of the King and Queen's College of Physicians. Dublin; Fannin and Co., Grafton-street. London: Longman, Green, and Co. 1867. Pp. 108.

FEW diseases have attracted more attention than phthisis. Nor need we wonder at this. Though not met with in every region of the globe, it is, at any rate, in one or other of its forms a very wide-spread affection. But it is more common in some countries than others, and of these Great Britain and Ireland come in for more than their share. It is just possible that this is due, in great part, to the vicissitudes of our climate. Whether this be so or not, the fact is certain that consumption is with us a very common disease. Though it must be allowed, also, to be a very fatal affection, still it is pleasant to think that the last quarter of a century has seen a very marked improvement in our treatment of the disease. The morbid anatomy may now be considered to be well known; also the natural history—that most important knowledge to the physician. But, above all, we have gained the greatest steps in the improved treatment of the present day. The introduction of the cod liver oil would alone form a new era in the management of phthisis. Not that it is to be considered a panacea for this formidable disease; but that properly used, that is, in suitable cases, and in suitable stages of the complaint, it has proved to be the greatest opponent—if we may so speak—to the advance of phthisis of any agent discovered in modern times: and if used at a stage of the disease when tubercles have not yet been deposited, there are the best grounds for believing that the patient may be completely cured. Independent, however, of the intrinsic value of the cod liver oil, it has taught the profession the great importance of the use of oily substances in general in the management of phthisis; such as are used in different kinds of food, so that there is now no better established fact in medicine than that these substances constitute very great helps in treating phthisis, and the state of constitution out of which it arises.

It has been just said that the treatment of consumption has made a great stride of late years, and we have glanced at some of the means adopted for the purpose. But there is still another aspect in which the subject can be considered, and not of less consequence than that of which we have been speaking. We mean what may be called preventive measures, and which of late have attracted much attention. It is in this point of view that the work before us has been written, the object of the writer being to impress on his readers the great importance of dealing with the constitutions of those who might be likely to get phthisis, before any changes had occurred in the lungs. That this is an object of the first importance admits of no question, and that when early consulted in such cases the physician can do a vast deal in preventing the onset of the disease is equally certain; and we give the author great credit for again bringing it under the notice of the profession. His observations are all sound, and show an accomplished physician; but farther than this we cannot go. We have used the word "again" advisedly, for we cannot give our author credit for any originality in this matter. In all the most recent works on phthisis there is, if we recollect right, much said about the prevention of the disease, and separate chapters are devoted—in some of them at least—to this special object. When one member of a family has been carried off by phthisis, it is only natural that the greater attention should be given to the survivors; in other words, that preventive measures should be adopted with them. And speaking of preventive measures leads us to say that we entirely concur with our author that the deposition of tubercle in the lungs is always preceded by a period more or less prolonged of what may be called bad health, and which very commonly, indeed, shows itself in some form of dyspepsia. In truth, the food is not assimilated properly; there is mal-nutrition, which may go on for months, or even years, and then a common cold, it may be, or sudden hæmoptysis at once usher in the disease, which goes on too surely to a fatal result. But as all these points are well put by our author, we must refer our readers to his work, in which they will find many practical remarks, bearing chiefly on means of preventing this fatal affection.

## The Medical Press and Circular.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, APRIL 3, 1867.

### THE MEDICAL ELEMENT IN THE HOUSE OF COMMONS.

It cannot be a matter of wonder that the Medical Profession has very little influence in the House of Commons, when we examine the constitution of that assembly, and find that when all other professions, trades, and pursuits are fully represented, Medicine is left almost without a voice in the Great Council of the Nation. From a summary recently published in a work named *Debrett's House of Commons*, we find the relative number of the members representing different interests, and the perusal is certainly both amusing and instructive. Thus, we find that there are no less than 128 members of the Bar, unequally drawn from England, Ireland, and Scotland, the English contingent being greatly preponderant; and there are nine who are, or have been, in practice as solicitors. Commissions in the army are, or have been, held by 112 members; commissions in the navy by 13, in the yeomanry by 65, in the volunteers by 68, and in the militia by 60—thus giving 318 members to represent the combatant elements. Authors and editors appear to the number of 81—128 are directors of public companies, 109 are bankers, merchants, manufacturers, or in business of a similar kind; and what, after this enumeration, is the proportion of medical practitioners? Why, *three* are, or have been, in the Medical Profession, and these three are, we believe, Dr. BRADY, who is no longer in practice; Mr. VANDER BYL, who has also relinquished Medicine for mercantile pursuits; and Mr. CLEMENT, who is the only avowed representative of our Profession. Such is the modicum of bread to the intolerable quantity of sack, when we compare the Medical element in the House of Commons with the hosts of placemen, lawyers, bankers, merchants, and officers in the army and navy, who make up the bulk of the popular branch of the Legislature. In the House of Peers, Medicine figures even more disadvantageously, for there we have never had a repre-

sentative at all, although the officers of the army and the navy, and the placemen, and the lawyers, and the bishops in addition, abound in scores.

The Universities of Oxford, Cambridge, and Dublin are all represented, and in any Reform Bill which may pass the Legislature, some other Universities will no doubt be admitted to the franchise; but why, we would ask, are the Colleges of Physicians and Surgeons, and other Medical Bodies in the three divisions of the British Empire, to be excluded from a participation in the boon which has been extended to other learned corporations? and why should the Profession of Medicine, numbering its members by thousands, and being surpassed by no similar class of society in learning, in influence, and in honour, be denied the right of pleading their own cause in the only assembly where their voice can command attention and respect?

When any question is started in the House involving the interests of the lawyers, it is edifying to observe the alacrity with which the discussion is taken up, and any attack on the supposed interests of the order is vigorously contested, and the same is the case with the military or naval professions, and with the Church, which last, fully represented in the House of Lords, has plenty of indirect supporters even in the Commons. But any question affecting the Medical Profession is either summarily disposed of, or is allowed to languish, or finally to die out for want of advocacy.

Now, we are not asserting that it is necessary for a large phalanx of Physicians and Surgeons to be present in the House of Commons in order to defend either their private or their common interests, although we should rejoice to find the proportion of medical men greatly increased; but we consider it absolutely essential that medical science should have some competent exponents in Parliament, in order to assist in the work of legislation and in the preparation of measures concerning the public health. The lamentable absurdities often advanced by Members when they touch on matters connected with Medicine or Hygiene might, at least, be counteracted by the intelligent utterances of educated Physicians or Surgeons competent to speak on the subject under discussion, and many measures of vital importance to the health of the community might be passed, if Medicine were not practically excluded from the walls of St. Stephen's.

Take, for example, the prevention of small-pox, and the adoption of efficient means in order to secure the performance of vaccination, and what a series of blunders and absurdities do we find committed in a matter, which, when viewed by the light of science and experience, admits of a simple and easy solution. Men who have been educated at Universities, and who may be supposed to have learned at least the elements of logic, hesitate to support measures for

the efficient vaccination of the people, although statistics have proved, in innumerable instances, the preventive character of this mild operation, when properly performed and universally practised, and, year after year, small-pox continues its ravages while the Legislature is *thinking* how to prevent them.

Again, have not the Medical Profession a right to demand that the representations of the Medical Council of Education and Registration should receive at least a respectful degree of attention from the House of Commons? That Council has repeatedly declared that the Medical Bill of 1858 is quite inadequate to fulfil the objects for which it was avowedly passed, and repeated entreaties have been addressed to the Ministry and to individual Members to support a measure having for its aim the improvement of this very defective enactment; but all their solicitations have hitherto been of no avail. Now, the object of the Medical Council being only to introduce such modifications as may distinguish medical men from quacks and impostors, is it likely that so modest a boon would be refused or disregarded if the Profession were represented in the British Parliament? Quack lawyers and quack soldiers are unknown, because the legal and the military professions take good care of themselves through their representatives, and it is unfair that Medicine, one of the most noble, useful, and ancient pursuits, should be left to struggle, as best it may, with the host of impostors who are allowed, with impunity, to sully its well-earned fame, and to rob it of its fair emoluments.

#### WIGHT V. WIGHT AND FIELD.

THE annoyances and persecutions to which medical men are constantly exposed, and the danger of losing character by which they are surrounded, have been once more exemplified in the case of Mr. FIELD. The verdict of the Divorce Court, it is true, completely justifies Mr. FIELD, and effectually rebuts the slur attempted to be cast upon him. But what a fearful amount of anxiety has thus been inflicted upon an innocent man. When we reflect upon the ease with which unprincipled persons may trump up charges of this description, we feel how great are the risks daily run by professional men in their ordinary avocations. The case under consideration illustrates this in more than one way. Here charges were actually brought forward in reference to transactions that occurred a dozen and fifteen years ago, and in support of them the idle gossip of a set of servants, who were at that period in the service of Mrs. WIGHT and Mr. FIELD, was submitted to the jury. We congratulate the defendants that their testimony was discredited, but we cannot conceal from ourselves the concern with which this state of things impresses us.

Mr. FIELD was fortunate enough to have a number of ladies and gentlemen, who knew all about the case, ready to come forward and speak of his character. But how would such a charge be refuted by a member of our profession practising in an obscure district, or living a retired life? It seems intolerable, but it is a fact that a medical man may, at any moment, have the purest reputation sullied by the malicious slander of a discharged servant. He may at any moment be called upon to refute baseless calumnies which present a certain plausibility from their being interpretations of facts connected with his every day duties, and when the breath of suspicion falls upon any one in such a case, how many "knowing ones" of the hard world will be ready to accept the charges without proof.

It is this view of our dangers which has doubtless moved some of Mr. FIELD's professional friends to express in a public and formal manner their sympathy with him. Last week a preliminary meeting presided over by Dr. SIBSON was held for this purpose, and as these sheets emerge from the press a public meeting is being held at the Marylebone Institution for the purpose of taking such steps as may be considered advisable in the matter. Dr. COPLAND, F.R.S., occupies the chair, and Dr. LONGMORE acts as honorary secretary. Our next impression will probably contain a report of the proceedings. Meantime, we are sure that a mere feeling of self-defence will secure for Mr. FIELD such an expression of sympathy from his professional brethren as cannot fail to afford him some consolation in the sad trial that has overtaken him. Whatever may be determined upon, we doubt not that the support of the Profession will be hearty and very generally diffused, and as the whole nation is known to cherish a hatred for all persecution, we see no reason why the public might not be invited to join in the movement.

#### SCHOOL OF PHYSIC IN IRELAND.

IN a leading article in our Special Edition for Ireland of the 13th of March, we fully informed our readers of the nature of the Bill, then before Parliament, on this subject; and we promised to give them the Bill itself as soon as its provisions had been definitely settled. In the present number we have much pleasure in redeeming our promise, and we give the Bill as it has passed both Houses, and now awaits the Royal assent.

#### CHOLERA REPORTS OF THE DUBLIN HOSPITALS.

THE Reports of the various Dublin Hospitals which admitted cholera cases during the late epidemic were laid before a meeting of the Medical Association of the King and Queen's College of Physicians, held on the evening of

March 27th, and will be discussed at the adjourned meeting of the Association, to be held on April 4th. We have carefully compared the various Reports, and shall now state the results of these comparisons, and in the following table we have endeavoured to epitomize the statistics contained in the Reports furnished by the Meath, Sir Patrick Dun's, Mater Misericordiæ, Mountjoy Prison, and House of Industry Hospitals:—

Name of Hospitals.	Admitted.	Died.	Recovered.	Deaths per cent.	Cubic space per Patient.	Attendants attacked.	Other Patients attacked.
Meath	130	67	63	51·5	Wd. 644·5 Shds. ...	2	2
Sir P. Dunn's...	180	85	95	47·2	2500	1?	0
Mater Misericor.	197	106	91	53·8	2000	0	0
Mountjoy Pris'n	9	4	5	44·4	<i>ad libitum</i>	0	0
House of Indust.	277	129	148	42·8	740	1-1?	5
Total...	793	391	402	49·3	1177	4 or 5	7

The total number of cases treated was 793; of these 391 died, and 402 recovered. As all the reports, except that from the House of Industry Hospital, include diarrhoea cases, we thought it right to add the similar cases to those of cholera, reported from that institution, thus lowering the rate of mortality from 66·3 (for purely cholera cases) to 42·8, which number appears to us most nearly to correspond with cases tabulated as cholera in the other hospital reports. The total average mortality from cholera in the Dublin Hospitals above mentioned was 49·3, in round numbers, 50 per cent., which corresponds closely with that of other cities where the epidemic prevailed. The epidemic reached its height in October, the number of admissions into each hospital having reached its maximum in that month; the total number of admissions being, for July, 1; August, 55; September, 173; October, 217; November, 81; December, 21. The Meath Hospital is not included in this estimate, as its report does not furnish the details. The females seem to have suffered more than the males, as shown by the reports from the House of Industry and Sir Patrick Dun's Hospitals. In the former of 148, 72 were males and 76 females. In the latter of 193 (genuine cholera), 80 were males and 113 females. The mortality also among the females seems to have been greater. In Sir Patrick Dun's the mortality was, males 41 per cent., females 44. In the Hardwicke (House of Industry) it was, males 60 per cent., females 70·8, showing a large balance against females; of the latter admitted into the Hardwicke Hospital a large number of them were aged, and among them the death-rate was remarkably high.

As regards the question of contagion we must say, in our opinion, the reports are rather against cholera, being considered contagious, except in a minor degree. The report from the Mountjoy Prison seems almost to include the possibility of contagion, and all the reports taken together show the disease at the most to be but slightly contagious, inasmuch as of the numerous attendants on 793 cases only 4 or 5 were affected by the disease. The great cubic-space in Sir Patrick Dun's is given as a reason for the good health of the attendants there, but this can scarcely have much weight in favour of thinking contagious particles were present, but rendered innocuous by dilution; for we find in the Hardwicke, where the number of patients

was very large, and the cubic space by no means so great as that in Sir Patrick Dun's, that there were *only* two individuals attacked; neither does the disease seem to have spread to any considerable extent among the ordinary patients, there being only 5 out of 428 in the Hardwicke, and 2 in the Meath, out of a large number, attacked by the disease.

As to treatment, all the reports seem to favour astringents, and to point to the inferiority of purgatives and calomel. In the Hardwicke, calomel seems to have been especially unlucky, numbering 31 deaths to 16 recoveries. None of the newer remedies (such as Calabar bean, camphor, &c.), seem to have rendered much effectual aid. At the Meath, camphor and chloroform were found valuable in allaying cramps of the stomach.

We regret we cannot reduce the statements from all the reports into one table from the manner in which they are constructed, although the general agreement between them is remarkable.

The report from the House of Industry is in every way superior to those from the other public hospitals. The Mountjoy Prison report is unique in exactness and in the arrangement of the details.

## Notes on Current Topics.

THE LATE PROFESSOR GOODSIR.—On the 20th March, a meeting was held by the medical authorities and other celebrities of Edinburgh to institute a Memorial to Professor Goodsir, and to commemorate his services in the cause of Medical Science. We shall best show the object of the meeting by referring our readers to a full report of the meeting which appears in to day's issue. By the resolution unanimously adopted it will be seen that the Goodsir Fellowship is conferred upon the student who has most distinguished himself in the sciences of anatomy and physiology. All the speakers paid a hearty and well deserved tribute to the late Professor, both as regards his scientific attainments and personal qualities. Nothing can be more fitting than to perpetuate the memory of a Professor in the University of which he was so conspicuous an ornament, and for which his name and services have done so much. A Committee was appointed to collect subscriptions, and frame regulations for the Fellowship, and we doubt not that a hearty response will be made to this appeal for the support and approval of his numerous admirers.

NEW MEDICAL BARONET.—The veteran Lawrence, Sergeant-Surgeon to the Queen, is numbered amongst the last list of persons promoted to the distinction of a Baronetcy of the United Kingdom. It would be superfluous for a medical journal to point out the claims to honour which the name of Lawrence may recall to medical men throughout the country. To the individual who has for so many years occupied a position which a dignity of this kind cannot raise, this recognition can be of little real value, while the distinction is not in itself sufficient to raise the gratitude of our brethren for the honour thus done to their Profession. Few, indeed, are the prospects offered by wealthy England to those of her children who devote themselves to the healing art. The church and the law have secured to themselves a large preponderance in our constitution, and their followers occupy numerous honour-

able and profitable positions. Medicine pursues its career unaided, uncared for, almost unprotected by the State, and those who embrace it as a calling thereby practically renounce wealth, titles, and influence. Abroad our Profession is much more respected, its members are much more frequently decorated. Last week we pointed out the niggardly hand with which social distinctions are conferred on our military and naval brethren. The announcement of a Baronetcy for Lawrence reminds us that in any other country he would have been recognized half a century ago. In spite of the immense benefits conferred on the community by the profession, we are completely excluded from higher dignities, and though including in our ranks scores of men who have achieved world-wide reputations our baronets may be counted on the fingers.

**OFFICER OF HEALTH, SOUTHAMPTON.**—The extra work imposed on Dr. MacCormack during the cholera epidemic has, it appears, been under the consideration of the Sanitary Committee, who have awarded him what he considers an insufficient payment. He has therefore addressed to them a remonstrance, which he has published, and in which he quotes an opinion given by Mr. Keane, Q.C., on the subject, which is as follows:—"That under the order in Council for putting in force the 'Diseases Prevention Act,' the services of the Officer of Health were not required to be given in consideration of his salary, and that he was clearly entitled to claim extra remuneration." Nothing is more fair than that every man should be paid in proportion to the work he has done; and as the services of Dr. MacCormack were required in an unusual degree in attending temporary hospitals and various other ways, it is to be hoped the committee will not disregard the remonstrance he has presented to them.

**CONVALESCENT HOSPITALS.**—Half the diseases and more, that flesh is heir to, owe alike their prevalence and intensity to the want of pure air. Watch the ruddy, wholesome countenance of the country resident, and compare it with the pallid and exhausted features of our city population, the difference is remarkable in the extreme; and to what is it attributable if not to their relative position and circumstances. The one who luxuriates in the fresh air of the open fields is the picture of health; the other who breathes by day and by night the sickening and depressing atmosphere of a crowded and polluted locality, if not the victim, is the ready prey of disease. So if the liability is thus plainly marked, the grasp of disease is not less so. Ordinarily, in the one case, it yields more easily to curative agency; in the other it is extensively powerful and destructive. While, then, we have in London, and other large and manufacturing towns, our hospitals and infirmaries to which the poor can gain ready admission, where they will be under the very best professional advice, and attended by most experienced nurses, indeed, where they have every thing best adapted to facilitate recovery, they remain after all more or less under those unfavourable atmospheric conditions which must still have an effect upon them, and retard to a considerable extent their recovery. Mrs. Gladstone is doing a praiseworthy work in the establishment of a Convalescent Hospital for the East end of London. We hope all will join heart and hand in the undertaking, that her object may be accomplished, and that the poor of that crowded district may have an opportunity of quaffing the sweet air of the country when they

leave their sick beds, and so gain a full measure of health before returning to their ordinary employments.

**ALARMING CATTLE DISEASE.**—A disease of a very alarming character has broken out among a herd of cattle belonging to Mr. John Mill, of Penpill farm, near Callington, Cornwall. Within a few days fourteen bullocks have succumbed to the disease, and several others are in a critical state. One pig has also died from the same cause. Several veterinary surgeons have examined the diseased animals, but have been unable to decide upon the nature of the disease, which they are all of opinion is not rinderpest. Professor Symons is engaged on an analysis and examination of the internal organs of some of the animals which have died. The outbreak has caused great uneasiness and alarm in East Cornwall.

**STRANGE AFFAIR.**—The *New York Times* of the 7th inst. makes the following statement:—"A terrible case of hydrophobia is chronicled in the Detroit papers. A little daughter of Mr. Alfred Woodruff, of the town of Greenfield, Michigan, was bitten some time ago by a dog, but no symptoms of hydrophobia were at first shown. At length the poison, which, acting as a sub-cutaneous injection, permeated every tissue of the system, broke out in a severe form, causing the most intense suffering. A consultation was had by physicians, who decided that, as the sufferer could not possibly survive, every consideration of humanity demanded that her sufferings be ended by some means, in accordance with which, during a severe paroxysm, the child was smothered to death."

**SOUTHAMPTON INFIRMARY.**—Whether in consequence of our representations or not, we are glad to perceive a somewhat more moderate tone in the discussion that is still going on respecting this institution. A letter by Mr. Scrase in the *Southampton Times* deals with the question in a very moderate spirit, and we trust that gentleman may, in any future discussion, meet with the consideration he deserves, for it is undeniable that many reforms, long pronounced needful, have not yet been effected, and the endeavour to attempt them is by no means an enviable task. It is singular that at this very moment a resignation should have occurred, and thus a touchstone will be applied in reference to the election of medical officers. Dr. Hearne, who has all along most warmly advocated some of the necessary reforms, has boldly offered himself as a candidate. This fact we learn from the advertising columns of a Southampton paper. Far removed as we are from the scene of the controversy, we are perhaps the more able to impartially urge conciliatory councils. The Governors of the Infirmary must be well aware of the ability of their townsman, and in a case like this surely they will forget the warmth of the late debate, and proceed to vote as conscience suggests for the good of the sick poor committed to their charge. Dr. Hearne was House-Surgeon under the late Liston at University College Hospital, where he gained the Gold Medal in Surgery, and took honours in Medicine, Materia Medica, Physiology, Chemistry, and Comparative Anatomy. He took the College and Hall diplomas in 1842-3, graduated M.B. at the London University in 1844, and took the Fellowship of the College of Surgeons in 1858. We do not know who may venture to oppose him, but certainly, apart from his large experience since his settlement at Southampton, he possesses credentials which are not

always found in candidates for appointments in provincial infirmaries. His election would prove the desire of the Governors to act justly by the charity, and be a guarantee to the profession at large that the reforms long declared essential should at least have fair consideration. The address issued by Dr. Hearne is such a model of independence and manly bearing that we extract it from the advertisement:—

“TO THE GOVERNORS OF THE ROYAL SOUTH HANTS INFIRMARY.

“MY LORDS, LADIES, AND GENTLEMEN—The Resignation of Mr. SAMPSON having created a vacancy in the office of Surgeon to your Institution, I tender my services with the view of testing whether you really seek the welfare of the poor by manifesting a desire to secure for them the aid of a Surgeon of experience—so much needed in the at present unfortunate position of the charity.

“Having waited with the hope that other experienced Surgeons would offer themselves for the post, I now take this step in consequence of having heard from influential governors that the absence of candidates precludes the possibility of their even expressing an opinion on the eligibility of the one selected by the dominant clique.—I am, my Lords, Ladies, and Gentlemen, yours obediently.”

### THE PATHOLOGY OF TUBERCLE.

SOME important investigations into tuberculosis have recently been made, to which we are desirous of directing attention. The interest that attaches to the subject is well illustrated by the courses of lectures at the London College of Physicians, of which we have given very accurate abstracts.

Dr. Reginald Southey selected as the subject of his Gulstonian Lectures, “The Nature and Affinities of Tubercle,” while Dr. Andrew Clark devoted the Croonian Lectures, which immediately succeeded, to a consideration of the “States of Lung commonly comprehended by the term Pulmonary Phthisis.” The two subjects, although distinct, are obviously closely connected, and lead to certain points common to the two, as will be seen from a perusal of the abstracts that have appeared in the last few numbers of the MEDICAL PRESS AND CIRCULAR.

Another indication of the zeal with which this subject is studied, will be found in a communication made by Mr. Simon to the Pathological Society last week. It appears that Mr. Simon has been recently carrying on some experiments respecting the possibility of inoculating tubercle, and specimens of deposit were shown, possessing, to the naked eye, the appearances of tubercular matter, which had been produced by inoculation in rabbits.

Those who had the pleasure of hearing the Croonian lectures at the College of Physicians will not soon forget Dr. Clark's account of his own experiments on rabbits, nor the very careful manner in which he guarded against too hasty inferences. It was therefore fortunate that he should have been present at the Pathological Society when Mr. Simon related his own valuable researches, and we append his remarks on the subject here, furnishing, as they do, an excellent addendum to his Croonian lectures, concluded in our last:—

“Dr. Andrew Clark having repeated M. Villemain's experiments at the time of their publication, and referred to them in his lectures at the College of Physicians last year, and having, moreover, some years before, with the assistance of Mr. Little and others, tried various experiments for the induction of phthisis, begged permission to offer a few remarks on the very interesting communication of the President.

“When pieces of fresh grey tubercle were introduced into a subcutaneous wound in the neck of the rabbit, a hard swelling or imperfect abscess formed at the spot in a few days, and in the course of two or three weeks, or even less, grey tubercles were formed in the lungs, and a little later in other parts of the body. These tubercles had all the naked eye characters of the grey granulation in man, and

so far, he could testify from repeated trials, that the experiments were conclusive. But the conclusions that the tubercles artificially induced were identical in nature with the grey granulation of man, and capable of indefinite propagation by inoculation, were to be received with the greatest reserve. For, in the first place, the grey tubercle artificially induced in the rabbit was essentially cellular in structure, whilst the ordinary grey granulation of man was essentially nuclear or corpuscular; secondly, the grey granulation of the rabbit was frequently absorbed; and thirdly, it never appeared to give rise to those secondary changes—pneumonia, fibrous degeneration, fatty usure, and emphysema—invariably induced, sooner or latter, by the grey granulation in the lung of man. Lastly, *Dr. Clark had succeeded in two instances in producing grey tubercle by the insertion of non-tubercular matter into the neck of the rabbit.*

“Now, the experiments of the President differed from those of other experimenters in some points of cardinal importance worthy of the closest examination. (1.) He made a slight wound. (2.) He used *yellow*, not grey tubercle; and (3.) instead of inserting little bits of tubercle he used only rather more of the matter of tubercle than he would have done of lymph if he had been practising vaccination. The experiments, moreover, differed in one at least of their results. In the President's cases no swelling or abscesses arose in the inoculated spot, one or other of which events had always happened in the hands of other experimenters. The President's experiments had been followed by the appearance of tubercle in the lungs and other organs; but, as Dr. Clark had not seen the specimens, and as there existed the loosest notions as to what was, and what was not tubercle, he reserved his judgment upon this important point.

“Dr. Clark, in conclusion, called the particular attention of the Society to the matter used for inoculation. When grey tubercle was used one might form a sufficiently (but not quite) accurate notion of the uniform character of the inoculating material; but when, as in the President's cases, *yellow tubercle* was used, one could not form, without further explanation, any just idea of what was meant by that term. For it was demonstrable that the yellow deposits in the lung indifferently called “yellow tubercle,” were very various in their nature, and in the majority of instances quite unconnected with the true grey granulation. Such so-called yellow tubercles might be the cheesy transformation of inspissated pus, unabsorbed pneumonic deposits, syphilitic nodes, hæmorrhagic extravasations, embolisms, and the like. If a pneumonic deposit under the name of yellow tubercle could produce grey granulations, plainly the whole complexion of the case was changed. Again, if the insertion of pieces of tubercle into the neck of the rabbit was essential to the production of the grey granulation, the experiment was not a mere affair of inoculation but of something else, of which he had spoken elsewhere. Lastly, if tubercle was inoculable in the sense that the syphilitic or vaccine virus was, tubercle would be more hereditary than it was; more communicable by husband to wife, and more common than happily it is among men engaged in the study of the pathological anatomy of phthisis.”

### SURGICAL SOCIETY OF IRELAND.

FRIDAY EVENING, MARCH 15, 1867.

Dr. BUTCHER, President of the College, in the Chair.

SYMES' AMPUTATION OF THE FOOT.

By EDWARD HAMILTON.

THE details of a case in which Symes' amputation of the foot was recently performed, may not be uninteresting to the members of the Society.

A boy, aged 18, was admitted to Stevens' Hospital on 29th of last December, suffering from excessive disease of both feet. They presented considerable deformity, as may be seen in this, the right foot traversed by numerous sinuses, with bone pro-

truding at several points. He states, that when a child, he hurt his feet while running along a ladder placed on the ground, and that they have continued sore ever since. The right foot could not be put to the ground, the least pressure or movement causing excruciating pain; he can support his weight with the left foot. This boy presented a most wretched appearance; he was emaciated, with that waxy complexion which indicates prolonged organic disease and an impoverished condition of the blood; he had slight sweats; his pulse was weak; and his heart's action very feeble; his chest and abdomen were carefully examined, but presented no evidence of phthisis or mesenteric disease. The question as to the propriety of amputation was thus a most delicate and anxious one, and it was determined, in consultation with my colleagues, to try if any improvement in his general health could be effected before anything in the way of operation was undertaken; accordingly, he was placed on nutritious regimen, with wine and the syrup of the phosphate of iron. Under this treatment he quickly improved, so that the operation was performed on the 10th of February. There was nothing in its details worth recording; the ordinary knife for excision was employed, respecting which I would caution my professional brethren against its being spoiled by the cutter, who sometimes continues its cutting edge round the extremity, which should be left perfectly blunt. You are thus enabled to push the soft parts from the bone without risk of transfixing and making button-holes in the flap. On sawing off the ends of the malleoli and the articular surface of the tibia the bone was found very soft and apparently diseased. This was gouged away to a considerable depth, and its appearance seemed to augur a very doubtful prognosis as to the result of the case, and caused us to watch with some anxiety for rigors or the blush on the cheek which so truly indicates the advent of osteomyelitis—fortunately such did not occur, and his progress was most satisfactory until the fifth day, when I was hastily summoned to see him at night, hæmorrhage having set in. On arriving at the hospital Dr. Symes, who was on the spot, had completely commanded bleeding by a tourniquet, and exposing the stump to the air. It was caused by the patient suddenly shifting his position in bed. From this, his recovery has been most rapid, and he now bears the firmest pressure on the stump without pain.

This is the fifth case in which Symes' operation has come under our notice within a limited period. Three of these have been recorded by my lamented colleague Dr. Symes, and I will now exhibit to the Society a patient on whom I operated eight months ago, who carries on his trade as a carpenter, without the least inconvenience; in all, the result has been most perfect success. They were all cases of prolonged disease, for which the operation is far more suited than for primary cases of accident. The integument on each side of the normal foot is too thin to make a good flap, and is consequently apt to slough, a result which I have never seen follow where the parts have become thickened by infiltration and hyperæmia from long-existing determination. In cases of long-continued disease where the parts had been thickened, and to some extent infiltrated, they could make a large and good flap to support the ends of the bones.

Dr. FLEMING said that the boy had been under his care in the Richmond Hospital for some time previous to his admission into Steevens' Hospital. He left the hospital of his own accord. During his stay in it he was extremely delicate, and in addition to the symptoms mentioned by Mr. Hamilton, a considerable amount of fever existed, and also bronchitis, which was then very prevalent. It was not easy to decide as to the absolute state of the lungs, or their perfect freedom from threatened symptoms of phthisis; and there was another reason for doubt as to the propriety of any operative proceeding—namely, considerable enlargement of the glands—not of the groin only, which he should not so much mind, but also of those in the neck and in the axilla. These had subsided before he entered Steevens' Hospital, and under the treatment there, his health very much improved. He thought the case was particularly instructive. Mr. Hamilton had said that there was not one of the bones of the tarsus free from disease, even the astragalus was diseased, the cartilage opposed to that of the tibia being so thin that it might be said not to exist. The cartilage of the articulating end of the tibia was not so much affected. Its cancellated structure was found to be soft and filled with tubercular deposit; this was scooped out at the time, and merely a shell of the compact substance of the tibia left, yet the reparative process had advanced so far that this boy could bear a large amount of pressure on the surface of the stump, as he had personally tested. This, in ad-

dition to the healing of the wound, proved that the curative processes underneath were progressing satisfactorily, and, moreover, without any apparent trace of periostitis.

The PRESIDENT observed that the points on which Mr. Hamilton had laid stress were worth consideration. He determined on this operation because the foot was destroyed, and he wished to save as much of the limb as he could, merely taking away the foot and the diseased extremity of the tibia. On removing the end of the tibia, he found the cancellated structure was carious, and he accordingly scooped out the diseased substance and turned up the flap over the bones. They often found in excision of the knee or elbow-joint that the texture of the bone was diseased as in this case. The proper course was to gouge out the diseased structure, as had been done by Mr. Hamilton. It was only a confirmation of a great fact which should never be forgotten.

#### FOREIGN BODIES IN THE URETHRA.

Dr. FLEMING exhibited a portion of a thorn twig, and one of a grass stem, each at least seven inches in length, and about the calibre of a No. 2 or 3 catheter, which had been introduced into the urethra to relieve retention of urine by men labouring under chronic stricture. In the attempts to remove them, the portions caught, broke off, and on reaching the hospital the proximal extremities of the foreign bodies were found to be at a considerable distance from the orifice of the urethra, and decidedly beyond the scrotal portion of it. With the use of a forceps which was exhibited to the Society, those foreign bodies were removed without any difficulty.

This forceps resembled that delineated in Mr. Thompson's work on lithotripsy and lithotomy.

Dr. FLEMING likewise exhibited other forceps which he had devised for a similar purpose.

#### URINARY CALCULI.—LITHOTOMY.

Dr. FLEMING also exhibited three specimens of urinary calculi of considerable size, which he had lately removed by lithotomy from children, aged respectively 12, 5, and 3 years. He detailed the most remarkable features of each case.

Dr. PERSE WHITE wished to have an expression of opinion from the Society on a case which had come under his notice. A boy was brought to him 6 years ago, and on making an examination he found that he had stone in the bladder. Not being inclined to operate himself, he sent the boy to Dublin, under the care of a distinguished hospital surgeon now dead. He was present at the operation, which was as skillfully performed as it was possible for it to have been. The calculus was of considerable size. He had an opportunity of watching the boy ever since. He suffered from stercoridism of urine. He was a healthy boy, and of peculiarly healthy family, was five years old at the time of the operation, and was now eleven, and there was a constant dribbling of urine, his clothes were wetted thereby, and he was in a wretched state ever since the operation. He mentioned the case as one of those unfortunate accidents that might follow the most skilful operation.

The PRESIDENT referring to the size of the stone mentioned the following case which had come under his notice. Some four or five years ago a boy was brought over here from Holyhead. He had been the subject of stone for six or seven years. He was then nine years old. So excruciating were his sufferings, that he was kept constantly in bed, with a large bolster under his hips, which had the effect of throwing back the stone from the sensitive neck of the bladder. From the position in which the boy was kept so long, his knee-joints were stiffened, and he was crippled. There was even found considerable difficulty in placing him on the operation table in a proper position. However, he was placed under the influence of chloroform, and a very large stone was extracted. He recovered, and at the end of seven or eight weeks they were enabled to straighten his limbs, and he went away perfectly well, and remained so. With respect to the case referred to by Dr. White, they might be certain the operation was well performed, notwithstanding the occurrence of stercoridism. He had seen that occur where the stone was large, and the neck of the bladder lacerated extensively in its extraction. If much force were used in drawing the stone through a small opening, weeping from the bladder would probably occur afterwards. In fact he did not think it could be said beforehand, where the stone was very large, that that condition would not occur. He had seen it occur under the best operations. In the case of children of tender age the traction should be most gentle, so as not to lacerate the urethra which was then so weak that it could be easily injured.

Dr. FLEMING observed that he had known incontinence of urine to occur after lithotomy in not a few cases where the operations were performed by the most eminent surgeons. This was of more frequent occurrence than many would suppose. He knew more than one person who had been operated on for stone, and who suffered from occasional stilticidium. One was rendered most uncomfortable by it, for if he went into society, slight excitement caused the urine suddenly to escape.

Mr. BARTON asked was there any circumstance in these cases to give Dr. Fleming an idea of the cause of the incontinence of urine.

Dr. FLEMING said he was not acquainted with the details of the cases. He only knew what had been the result after the operations.

#### BATONNET WOUND OF ABDOMEN.

Dr. PERSSE WHITE said—Mr. President, the pathological specimen which, by the kind permission of Mr. Macnamara, I have the honour of laying before you this evening, was taken from the body of a Fenian who was stabbed by a policeman on the Tallaght-road, about one o'clock on the morning of Wednesday, March 6th; he was a fine well-made man of twenty-six years of age. At about fifteen minutes to nine on that morning, I was called on by a policeman to visit the wounded man. I found him in the waiting room of the Roundtown Dispensary lying on his back on the floor, he was quite composed and sensible; complained of some pain in the epigastrium, but none elsewhere. On removing a coarse cloth which covered the abdomen, I found an enormous mass of intestine protruding from a small wound of not more than three-fourths of an inch in length, and situated in the lower part of the abdomen about three inches below the umbilicus, and two inches from the median line, its long axis being nearly horizontal; it was clearly the wound of a semi-sharpened sword.

The protruded intestines were covered with chaff, oats, &c., and were in a state of intense inflammation, covered with lymph, and exuding bloody serum, in fact, a case of active peritonitis external to the body; there was not a sign of hemorrhage; he stated that he had walked fully a mile after receiving the wound, holding the protruded intestines in his hand.

I had him at once removed to a warm room, for the cold air gave him great pain when the intestines were uncovered, and first cleaning them with warm water, attempted to return them; this I found to be impossible, for they were much distended, and the wound so small. I then put him under the influence of chloroform; enlarged the wound to about twice its original size, and returned the intestine bit by bit, using no violence or force of any kind (my friend Dr. Davy kindly came to my aid and attended to the administration of the chloroform for me). I then closed the wound with thin points of wire suture, put on a large pad and bandage, and gave him a full opiate and some wine. The police then had him removed to the Meath Hospital. At one o'clock I saw him with Mr. Macnamara, under whose care he was placed, he was then semi-collapsed, but apparently doing as well as possible, he was put under the usual opium treatment.

Mr. Macnamara saw him at half-past five P.M., when he was doing well; beginning to rally from collapse; and at ten P.M., when visited by Mr. Russell, the resident pupil, he was apparently better; had conversed with those about him and taken some nourishment; a few minutes afterwards he died.

I was not present when the post-mortem was made by my friend Dr. Foot, but the parts here exhibited, show the amount of injury done internally; the intestine and mesentery are perforated in no less than six places, yet Mr. Foot has told me, that there was no hemorrhage, or no extravasation of the contents of the bowels, but that there was some slight extravasation along the spine beneath the peritoneum; the wounded portion of intestine was not much inflamed, but the portion which had been protruded was already glued together by adhesive inflammation.

Principal Sir David Brewster, Dr. Christison, Dr. MacLagan, Dr. Lyon Playfair, C.B.; Dr. Smith, P.R.C.P.E.; Mr. David Smith, F.R.S.E.; Mr. John Muir, LL.D.; Professor Blackie, Drs. Andrew Wood, Begbie, Littlejohn, Benjamin Bell, Sellar, Saunders, Ormond, Handyside, Gairdner, Matthews Duncan, Combe, Moir, Dyce, Menzies, Burn, Scott, Balfour, Crum Brown, Lowe, Millar, Hardie, Joseph Bell, Gamgee, T. G. Balfour, Turner, &c.

On the motion of Sir DAVID BREWSTER, Dr. Dunsinure, President of the Royal College of Surgeons, was called to the chair.

The CHAIRMAN remarked that the scientific eminence and personal qualities of the late Professor Goodsir had not only secured for him a world-wide reputation, but had endeared him to all who knew him, or who had come in contact with him. He thought that there could be no difference of opinion as to the propriety of taking some steps for instituting a tribute to the memory of one so much appreciated and esteemed.

Dr. SMITH, President to the Royal College of Physicians, moved—"That this meeting, deploring the loss which science has sustained by the death of Professor Goodsir, resolves that steps be taken to form a lasting memorial of his distinguished career as an original investigator and teacher of anatomy and physiology." He said he had much pleasure in moving the first resolution. But before doing so, he would beg to express in a few words his hearty agreement with the object of the meeting. The name and the fame of Professor Goodsir had done much to sustain and advance the high position of the University and the medical school. He therefore thought they were called upon to do something to mark their high estimation of those great talents and original cast of mind which characterised him, and enabled him, both as an investigator and a teacher, to do so much for his favourite science, anatomy, as well as to diffuse a knowledge and a love for it among the numerous pupils who flocked from all quarters to hear him. It had been remarked that he had left few writings behind him on his favourite science; but when they took into consideration the infirm state of his health during a long period of his professional life, it would not surprise them that he did not write more, but that he was able to accomplish what he did, both in writing and teaching. Nothing but an enthusiastic love of his science, and his great interest in his pupils, could have enabled him to go through the laborious duties of his chair. The sympathy which existed between him and them, and the enthusiasm with which he inspired them, were remarkable; so that his love for the science of anatomy and his original views would, he had no doubt, be deeply impressed upon many of them, from which they might expect the happiest results.

Professor CHRISTISON seconded the motion. He said he was thoroughly convinced that a movement to perpetuate the memory of Professor Goodsir in some way or other would be most successful, from the number of his pupils that existed throughout the world. He had made a calculation, and had come to the conclusion that upwards of 4000 gentlemen had attended the instructions of Professor Goodsir; and when he thought how much esteemed he was by those pupils, he had little doubt that the present movement would meet with great success.

The resolution was unanimously agreed to.

Mr. DAVID SMITH, Treas. R.S.E., moved the second resolution, which was as follows:—"That the most appropriate manner of commemorating Professor Goodsir's services as an investigator and teacher is the establishment in the University of Edinburgh of a Fellowship in Anatomy and Physiology, to be called the 'Goodsir Fellowship.'" He cordially agreed in all that had been said with regard to the estimable character of the late Professor Goodsir. He might require to make some apology for taking part in the proceedings of the meeting, consisting, as it did, chiefly of medical men; but the ground on which he thought his appearance there was justified, was that the establishment of an adequate memorial to a man of such eminence as Professor Goodsir should not be confined to the profession to which he belonged, but should be shared in by the scientific world and the general public who had been largely benefited by his contributions to science. The resolution contained three propositions. The first was that the establishment of a Fellowship was a more appropriate manner of commemorating the services of a man of such eminence as Professor Goodsir than any monument of stone or lime, however enduring. The second proposition was that the Fellowship was to be one in anatomy and physiology, and would be a means of enabling young men who had shown an aptitude for these sciences to devote a portion of their time to it, which

#### PROPOSED MEMORIAL TO PROFESSOR GOODSIR.

(From the Edinburgh Evening Courant, March 21st, 1867.)

A MEETING was held in the hall of the Royal College of Surgeons yesterday afternoon, to take steps for commemorating the services rendered to the cause of medical science by the late Professor Goodsir. Among the gentlemen present were—

otherwise they would have been compelled to relinquish in order to engage in the practice of their profession. He believed that if Professor Goodsir could have been present and spoken, he would have felt there was nothing more gratifying to his own feelings than that his name should be associated with a movement calculated to advance the science which he so ardently loved and so successfully cultivated. Upon the third point he need say nothing, as all present would cordially agree that the proposed Fellowship should bear the name of Professor Goodsir.

Dr. MATTHEWS DUNCAN seconded the resolution; and expressed his belief that they would be able, in the manner contemplated in the resolution, to bring out the latent genius of young men, who, after prosecuting their studies by the aid of this Fellowship, might be able to advance the sciences of anatomy and physiology, and thus reflect lustre upon the school of medicine in Edinburgh.

Dr. BEGBIE moved—"That the following gentlemen be appointed a committee, with power to add to their number, to collect subscriptions for the above purposes, to frame regulations for the Fellowship, and to report to a future meeting of subscribers:—Sir David Brewster, Dr. Christison, Dr. Smith, Dr. Eürt, Dr. Dunsmore, Mr. Syme, Dr. Andrew Wood, Sir James Y. Simpson, Bart., Dr. Saunders, Dr. Handyside, Dr. MacLagan, Dr. Matthews Duncan, Dr. Joseph Bell, Dr. John Muir, LL.D., Dr. Craig MacLagan, and Mr. David Smith—Dr. Craig MacLagan, F.R.C.P.E., to act, as honorary secretary." Dr. Begbie stated that the committee he had named was formed of gentlemen connected with the University, College of Physicians, and College of Surgeons, to form the nucleus of a large committee to carry out the objects of the meeting.

Dr. LYON PLAYFAIR pointed to the importance of that clause in the resolution which gave the committee power to add to their number, as it would enable them to add members who had received benefits from the late Professor in all parts of the world.

Dr. JOHN MUIR, LL.D., in seconding the resolution, said that he was very sanguine of the success of this movement, considering the reputation of Professor Goodsir and the object which the meeting had in view. He spoke upon practical as well as theoretical grounds. His friend Dr. Charles Murchison, in London, by his activity had succeeded in collecting a considerable sum of money, out of which there was to be created a Fellowship in natural science in the University in commemoration of the late Dr. Hugh Falconer, of the Bombay service. When he considered that Dr. Falconer was only known as a man of science, and had never been a teacher, and having heard the statement as to the number of gentlemen who had received instruction from Professor Goodsir, he could have no doubt but that the movement would be eminently successful.

Professor MACLAGAN moved a vote of thanks to Dr. Dunsmore for presiding, and to the College of Surgeons for the use of their hall.

The meeting then separated.

### THIRD REPORT

#### ON THE PROGRESS OF PHARMACY,

SUBMITTED TO THE BRANCH MEDICAL COUNCIL (IRELAND),

By WM. DANIEL MOORE, M.D., Dub. et Cantab., M.R.I.A.;  
EXAMINER IN MATERIA MEDICA, PHARMACY, AND MEDICAL JURISPRUDENCE,  
IN THE QUEEN'S UNIVERSITY OF IRELAND.

In continuation of the discharge of his duty as Reporter on the Progress of Pharmacy to the Branch Medical Council (Ireland), Dr. Moore has submitted to the Branch Council the following summary of papers in the several foreign journals named in his second Report.

#### ACCELERATING THE PROCESS OF FILTRATION.

In the *Journal de Pharmacie et de Chimie* for May, 1866, p. 355, M. Picard proposes a mode of accelerating the process of filtration, which may be thus stated:—A paper filter, without folds, adapting itself exactly to the walls of a conical glass funnel, is introduced into the latter; the paper is moistened with the finger, care being taken to remove any bubbles of air which may remain between the paper and the glass. By means of an Indian rubber tube, the lower part of the funnel is made to communicate with a glass tube, about forty inches in length, narrow enough to prevent the column of liquid dividing in it, and bent circularly at the upper part, near the Indian rubber tube.

The whole is placed in a vertical position, and the fluid to be filtered is carefully poured into the funnel. The first portions of the filtered liquid collect in the curve of the long tube, which serves to maintain a constant column of liquid, and causes the latter to act as an exhauster, so soon as the fluid begins to descend in the rectilinear part of the tube.

It is said that in this way filtration is accomplished ten or twelve times more quickly than by the ordinary method.

In the number of the same Journal for December, 1865, p. 425, is a useful paper, by M. Guibourt, on the *meccidinal weights* of Europe, compared with the metrical system. Having given a Table in which the different weights of the several countries are reduced to their value in grammes, and having added remarks upon many of them, the author devotes a large portion of his essay to the consideration of the weights and measures made use of by the pharmaciens of England. He gives an example of the mistakes caused by the complication of weights and measures:—"In the French edition of the London Pharmacopœia, published in 1837, the wine pint of 0.473 litre or 473 grammes of distilled water has been taken as the basis of comparison with the French weights, instead of the imperial pint of 0.566 litre. The result is, that, dividing 473 grammes by 20, this work has given, as the weight of the fluid ounce, 23.6 grammes; as that of the fluid drachm, 2.957; and for the minim, 0.040 gramme, which a typographical error has made 0.40 gramme. It is easy to imagine," adds M. Guibourt, "what lamentable errors may have been the consequence of this publication."

The author proceeds to criticise the abolition for weights—not for measures—of the drachm and scruple by the framers of the British Pharmacopœia, and advocates the use of the balance in determining the quantity of a fluid, expressing his approval of the later Prussian Pharmacopœias, which admit no measure for liquids; and of the Bavarian Pharmacopœia, which allows only fluids of slight activity, prescribed by ounces, to be measured. He also advocates strongly the adoption of the metrical system; but I cannot see that any advantage would be gained by the adoption of the plan of weighing fluids, and there is no doubt that such a method would certainly be attended with great additional trouble and inconvenience.

The same number of the Journal has, at page 408, an article by M. Müller, on the preparation of *Phenic* or *Carbolic Acid* of which publication I have given a translation in THE MEDICAL PRESS AND CIRCULAR, 1865, p. 505.

The number for July, 1866, pp. 48, 49, has papers, by M. Perret, on the manufacture of *Citric Acid*, and of the *Citrate of Magnesia*.

#### PICRIC ACID AS A TEST OF PRUSSIC ACID.

In Buchner's *Neues Repertorium für Pharmacie*, Band xiv., 1865, p. 545, Professor A. Vogel recommends *Picric Acid* as a very sensitive test of the presence of Prussic Acid. If a moderately concentrated solution of Cyanide of Potassium be mixed with a watery solution of *Picric Acid*, a deep dark-red colour ensues upon the application of heat, and after a few minutes increases considerably in intensity. The author found this reaction to be still perfectly distinct when Prussic Acid was diluted with 30,000 parts of water. If the dilution be very considerable, the coloration is not remarkable until the fluid has been boiled for a long time, and subsequently allowed to stand.

The author remarks that *Picric Acid* is peculiarly adapted for demonstrating in a simple manner the Prussic Acid known always to occur in tobacco smoke. The smoke is led by means of an exhauster into a solution of caustic potash; the latter is diluted, mixed with *Picric Acid*, and boiled, whereupon the characteristic coloration immediately occurs.

#### ACONITIA.

In the number of the *Journal de Pharmacie et de Chimie* for February, 1866, p. 113, is a translation from the *Chemical News*, 1863, vol. ix., p. 87, of Mr. Proctor's remarks upon the comparative richness in *Aconitia* of the roots of European and American *Aconite*. Mr. Proctor obtained from 1000 parts of American root of *Aconitum Napellus* 4.2 of nearly pure *Aconitia*, while the European roots furnished only 2 parts per 1000.

#### AMMONIACUM.

Dr. August Vogl, of Vienna, publishes, in Buchner's *Repertorium*, 1866, No. 2, p. 73, some notes upon the source of *Ammoniacum*. This gum resin is, he says, at least in greatest part, not a product of a specific secretion, but of the disorganization of vegetable cells—an observation nearly identical with that made by Wigand (Priingsheim's *Jahrb.* III., 1863, pp. 146, 147), respecting *Ammoniacum*, *Assafetida*, and *Opoponax*,

## BITTER PRINCIPLE OF BITTER ORANGE PEEL.

M. Blottière pharmacien, publishes in the *Bulletin général de Thérapeutique*, 1865, tome 69, p. 549, some researches on the bitter principle of bitter orange peel. He prepares a watery extract of the rind, from which he takes up the bitter principle by alcohol, leaving inert and fermentible mucilaginous matter, which, he says, constitutes nearly one-third of the original watery extract, and with this alcoholic product he proposes to prepare a syrup more uniform and stable than that of the French codex. It seems to me that the framers of the British Pharmacopœia, by directing the syrup to be prepared with the tincture, have accomplished the same object in a simpler and easier mode.

## COLCHICIN.

The number of the *Journal de Pharmacie et de Chimie* for December, 1865, at page 490, contains an abstract of two papers, by Messrs. Ludwig and Hubler, upon *Colchicin*, the originals of which appeared in the *Archiv der Pharmacie*, Band cxi. pp. 10, 194. M. Ludwig prepares this principle by exhausting colchicum seeds with hot alcohol, adding to the liquid about twenty times its volume of water, which separates an oily matter, treating with basic acetate of lead, to eliminate the colouring matter, and then with phosphate of soda to separate the excess of lead; lastly, he adds tannin which precipitates the colchicin.

To isolate the colchicin, the precipitate, consisting of three equivalents of this principle and two of tannin, is pounded with an excess of washed and moistened litharge; the mass is then dried in a water bath, with agitation. To ascertain that the tannin is fixed, a small portion is boiled with alcohol; the filtered fluid ought not to turn blue on the addition of sesquichloride of iron. If it should do so, the mass must be again mixed with water, and dried in the water bath.

The colchicin is separated by means of boiling alcohol; it is dried *in vacuo*, over sulphuric acid. By repeating these operations, the principle is obtained in a state of purity.

As M. Oberlin has shown, it is incorrect to class colchicin among the alkaloids. It is indifferent with respect to acids, and if it forms with these a crystallizable compound, the latter includes absolutely only the elements of colchicin.

## SOLIDIFICATION OF BALSAM OF COPAIVA.

M. Rabot suggests, *Journal de Pharmacie et de Chimie*, 1865, p. 445, a modification of the plan proposed by M. Roussin for the solidification of Balsam of Copaiva, and described in my second Report, the object of the modification being to effect the instantaneous solidification of the balsam. Pure balsam of Copaiva is mixed in a capsule with one-sixteenth of its weight of calcined magnesia, slightly hydrated by the aspersion of a few drops of water (about one-tenth of the weight of the magnesia). The capsule is then plunged into boiling water, and the mixture is shaken, being, at the same time, held for some minutes in the water bath. The author adds, that the process is equally applicable to *turpentine*, and that by its means both medicines may be advantageously prescribed in the solid form, without the loss of any of their properties.

## CURARE.

The same Journal has, at page 296, a paper by M. W. Freyer, on the active principle of *Curare*; and in the *Bulletin général de Thérapeutique*, Oct. 15, 1865, p. 294, may be found a paper, by Dr. Jousset, on curare in a therapeutical point of view.

In the latter Journal, for 30th March, 1866, p. 241, is a paper by M. Gallard, on the employment of large doses of *Digitalis* in the treatment of pneumonia.

M. Carlo Parvesi proposes (*Journal de Pharmacie et de Chimie*, January, 1866, p. 49) to preserve protiodide and protosulphate of iron by enveloping them with a very dense solution of gum arabic, which is subsequently dried in a heated stove.

## LEECHES.

In the number of the same Journal for February, 1866, p. 123, M. Labache proposes to preserve leeches in water containing a quantity of *Fucus crispus* (Carrageen). The vessels are placed in a situation where the temperature varies between 68° and 77° F., and the water is renewed only once a day. The author supposes that the leeches find nourishment in the mucilage formed by gradual solution of the fronds.

In the *Bulletin général de Thérapeutique* for 15th April, 1866, p. 308, M. Stanislas Martin objects to the foregoing plan, on the ground that notwithstanding all care to change the water frequently, it alters rapidly; and that, if the leeches are

fed, they will be less likely to take when required. M. Martin advises instead, to cover the bottom of the vessel with a bed of flints of various shapes, and of a size not exceeding that of a hazel-nut. The leeches love to sojourn in the cavities formed by the flints, and in entering them rub against the asperities of the stones, so getting rid of the filamentous mucosities which embarrass them.

(To be continued.)

## Correspondence.

## QUACK ADVERTISERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It was not my wish to trouble you with further correspondence, but I am obliged to reply to some editorial remarks appended to my letter of 11th inst., which appeared in last week's issue of THE MEDICAL PRESS AND CIRCULAR. I shall not add anything to what I have said as to a publisher's duty in reference to "quack" advertisements, but I wish to state, with respect to your comments, that if I am the vendor of any of the so-called nostrums to which you object, I am not aware of it, and shall be glad to know what they are? I am a wholesale drug merchant, doing almost nothing in the retail way, and only keep in stock such patent articles as are in general demand by the retail chemists and druggists; and, I believe, that I do not keep any articles that may not be had from all the first wholesale drug merchants in this city. You may know more of these medicines than I do, but if I were not to keep them in stock for my wholesale customers, I might in fact go out of the business altogether. Many of these patent medicines are old established remedies that have been advertised into notoriety, and a demand thus created for them. They may be of much value or little; but that is a matter which must be left to the public, and the latter insists on having what it wants, and will accept nothing else. With regard to the "promulgators" of the nostrums in question, I do not possess one scintilla of information over or above what you possess yourself, having no direct business communication with any of them; but, I am aware, that in advertising matters they pay their way as other men of business do, and leave no ground for complaint on that head. This is all I know of these parties, of their private character I know nothing one way or other, and of their professional status, or want of it, I am equally ignorant. I advert to these matters purely in self defence; because, in your editorial comment, it is insinuated indirectly that I am "hand and glove" with the quack doctors, whereas in truth I have never seen or corresponded with one in all my life.—Yours truly,

THOMAS HACKETT.

P.S.—I may remark that the advertisements to which you object sometimes find their way into strange quarters. It is not long since a certain Dr. Napier advertised a notorious "Quack" Essay in your own columns, and I can testify that it appeared weekly for several months therein. T. H.

[We have no reason to believe that the book alluded to as having been advertised in our columns deserves the name of a "Quack Essay." We have not seen the book. We don't know who Dr. Napier may be. The advertisement came to us through a respectable house, and did not contain any appearance of quackery.—ED. M. P. & C.]

## THE FUNCTION OF ELECTRICITY IN THE ANIMAL ECONOMY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—It is really wonderful how far men have pursued in times gone by their ridiculous theories and absurd opinions with regard to medicine and medical science, and it would seem that the time for men of coining new and ludicrous theories has not yet come to a close.

Dr. Caplin, apparently not being satisfied with the numerous theories which have been from time to time promulgated, with regard to what life is, or the vital force, whatever that may be, which presides over the processes of living beings, has hit upon a new idea, or at least has attributed more to electricity than has hitherto been generally accorded to it by others, and has, by so doing, added another chemra to the already too voluminous list of fanciful speculations. He would, it seems to me, be inclined to put electricity in the place of what Hunter called the "materia vital," or Muller the "organic force," and

refer to it as a cause of all the numberless, varied, and complicated processes which take place in the organism, whether it be that of excretion, secretion, or locomotion, as invariable effects.

Dr. Caplin looks upon the human body as a "decomposing machine," in which electricity is the sole and only cause of the innumerable processes which take place therein. True it is, that he admits, to my mind somewhat reluctantly, that it is sometimes an effect; would it not be more consistent with what is known of the nature of electricity, and of the animal body, to regard the development of electricity as always and invariably an effect of the natural processes which are constantly going on during life?

I think nothing can be more absurd than likening the body to a steam engine, the stomach to a boiler, wherein the steam is generated which sets the human machinery agoing, and also the sweeping assertion that makes electricity a *sine qua non* in the developmental, nutritive, and generative processes.

It is a pity that the time and energy of an eminent man should be prostituted for the furtherance of a wild fantasy, a mere theory, the truthfulness of which no one believes in, and the existence of which is only to be found in the fertile imagination of Dr. Caplin.—I remain, sincerely yours,

G. V. THOMPSON.

## Medical News.

**COMPLIMENTARY DINNER.**—The present and former pupils of Dr. Mapother intend entertaining him at dinner and presenting him with an address at the Gresham Hotel on Saturday next, the 6th of April, at half-past six o'clock, on the occasion of his elevation to the chair of Anatomy of Physiology in the College of Surgeons.\* Any gentlemen wishing to join in this movement will please communicate with G. A. Curran, Esq., Royal College of Surgeons

**THE HEALTH OF LIVERPOOL.**—Dr. Trench, the Liverpool medical officer of health, has prepared a very able and exhaustive report on the health of the town during the past year. That year was one of unusual trial and pressure. During the earlier part of the year typhus fever and lung diseases were very fatal, and ran up the number of deaths to much beyond the usual limit. But even this heavy mortality became insignificant compared with the frightful fatality of cholera and diarrhoea in the third quarter of the year. The total number of deaths during 1866 was 20,193, being at the rate of 41.7 per thousand for the whole borough. Speaking of the rise and progress of the outbreak, Dr. Trench says:—"The lines of the cholera rise and decadence—of its advance and retreat—are symmetrical, very similar, and almost uninterceptedly regular. The philosopher is able, from the known and determined quantities of force and attraction, to predicate the form of parabola which a projectile will assume; but neither physician nor statistic can tell why cholera rose to a certain height and then, as seen in the diagram, returned to the plane by a route bearing to the axis of the cone or pyramid the same figure and equi-distance, and what is still more astonishing, occupying almost the same time in its descent as did the line of its elevation. The pestilence began as an epidemic in the first week of July, and took eight hebdomadal periods to reach its apogee, then declined in force, and within the same measurement of time had, by the 1st of November, reached the plane gradually to disappear. Its rise in the first eight weeks cost 759 lives, it then rested for a week at its apogee and accounted for 193 deaths; its descent in the second eight weeks cost 773 lives." Dr. Trench appears to regard the second outbreak as quite distinct from the cases of the *Helvetia*; and gives a startling account of what he deems to have been the real outbreak of the disease in the town:—"On Monday morning, the 2nd of July, information was received at my office from the Registrar of Exchange Ward that a death certified to be from "English cholera" had occurred on the evening of the 1st, at No. 2 Court, Bispham-street. The locality is one only too well known to the sanitary officers, being inhabited by the lowest of the Irish population, and situated in the worst part of what may be justly described as the chief fever district of the parish. The court itself contained three straight up and down houses, and an open midden. It was altogether so close, confined, and unfit for human habitation, that the grand jury had, in July, 1865, confirmed my

presentment, and ordered the demolition of two of the houses and the conversion of the common cess-pool into a water-closet; and there only awaited some legal or other formalities to have the order carried into effect. The probability was only too evident that in a neighbourhood so squalid and overcrowded, and among a population so indigent and wretched, the spark, if of the true contagious cholera, would burst into a conflagration; therefore immediate efforts were made, both by the relieving officers and myself, to induce the friends of the deceased to consent to the speedy burial of the corpse. The family refused to listen to our counsels, and elected to keep the body until Tuesday, in order that it might be waked during the night watches of Monday. It was laid on a board on the floor of the lower or sitting apartment of the cottage, and in this room, where men and women eat, drank, and slept, the orgies of the coronach, embracing the co-operation of scores of people, were maintained, amidst drunken and profane ribaldry, during the day and night. When I again went on the Tuesday morning, to try either by threats or persuasions to hasten the funeral, I found the whole place reeking with tobacco smoke and with the loathsome and disgusting emanations of drunken unwashed bacchanals. The three houses were crammed with men, women, and children, while drunken women squatted thickly on the flags of the court before the open door of the crowded room where the corpse was laid. There had been, in the presence of death, one of those shameful carousals, which, to the disgrace of the enlightened progress and advanced civilization of the nineteenth century, still lingers as dregs of ancient manners among the funeral customs of the Irish peasantry. It was a rash challenge to the dreaded pestilence; and how and with what fearful results accepted, the mortality returns of the next four months will too clearly show. Suffice it now to mention that before the period of a week had passed, John Boyle, the husband of the woman, was also among the dead, and before the end of July forty-eight persons had died from cholera within the radius of 150 yards from the court which had been the scene of the ill-timed revelry.

**TREATMENT OF PATIENTS IN COLNEY-HATCH LUNATIC ASYLUM.**—At a late general meeting of the magistrates of the county of Middlesex, Mr. H. Pownall, who was in the chair, drew the attention of the court to a letter sent to the Commissioners of Lunacy, in which it was stated that a patient named Harrison had been put to bed in No. 5 room in D ward of Colney-Hatch Asylum in a state of nudity, without bedding of any kind; and that another patient, named Hobbs, was so treated for 140 nights during the winter of 1864 and 1865, and that he died one morning soon after being unlocked. The committee of visitors of the asylum, with a view to afford Dr. Sheppard an opportunity of refuting these charges, invited his attendance at a meeting of the board on the 18th ult. He at once admitted that the statements contained in the letter were substantially true, and that a similar mode of treatment was adopted as a system in cases wherein patients, by tearing and biting, habitually destroyed bedding and clothing, and even the lining of padded rooms. Harrison and Hobbs were patients of that character; they would in a short time after being placed in their rooms, and supplied with clothing and bedding, tear them to shreds, even the strongest dresses and quilted coverlets. The instructions to the attendants are to warn patients with such propensities that if they were found to have destroyed their clothing or bedding they would not be allowed any. Locked leather gloves had been found useless. As to the use of such gloves, when used they were not deemed to be or entered in the medical journal as mechanical restraint. Dr. Sheppard further stated that the medical books contained no record of the confinement of patients in a state of nudity, as above described. The practice now for the first time brought to the knowledge of the commissioners was in their judgment so much to be condemned, and affected so gravely the character of the asylum, that they suggested an immediate and full inquiry on the part of the committee. The commissioners add, that in all their experience they have met with no case of insane patients to which such treatment as that described could properly be applied, or would admit of any kind of justification. In a communication to the committee of visiting justices, Dr. Sheppard states that Hobbs was not placed in his room in the manner described for more than four nights out of sixty-seven, and that the statement that Harrison had been shut up in his room for ten successive nights without bedding or clothing was not true. This communication was transmitted to the Commissioners of Lunacy, who understand that the objections to the treatment in question are equally entertained by the commit-

tee, and that no recurrence of the practice will be permitted. Some discussion took place, and the report was put and agreed to.

**BEQUESTS.**—Mr. John D. Middleton, lately deceased, has bequeathed £200 to each of the undermentioned hospitals—viz., the Westminster, the Middlesex, the Charing Cross, and Convalescent Hospitals.

## Notices to Correspondents.

All Contributions are attentively considered, and unaccepted MSS. are returned on receipt of stamps for postage; but the Editors cannot be responsible for any accidental loss, nor can MSS. or replies be delivered on personal application.

Contributions should be legibly written, and only on one side of the paper.

Dr. Andrew Clarke's Third Croonian Lecture is unavoidably postponed—the proof not being corrected in time for this issue.

Dr. Griffith shall have a private note.

*Dr. Skilton, Monaghan.*—To obtain registration under the Medical Act the applicant must forward his diploma to the Medical Registrar for the Branch Council of the division of the United Kingdom to which he belongs. In Ireland, to Dr. Steele, at the office, Dawson-street, Dublin. The fee payable for practitioners qualified before 1858 is £2; for those qualified subsequently £5; for registration of any new diploma on the part of a practitioner already registered, 5s.

*L.R.C.S.I.*—The tendency to varicose veins will disqualify, as they interfere greatly with powers for long marching. There is a searching medical examination.

### ERRATUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Please correct an error which appears in my communication "On the Treatment of Delirium Tremens by Indian Hemp." Instead of "3ss," 3ss. of the tincture was given every second hour.—By inserting this you will oblige, yours, very truly,  
HENRY BROWN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

MY DEAR SIR,—Your paper with Memorial to Lord Naas, March 13th, duly to hand. I write now to say that Dr. Tyrrell has handed me over £1 1s. for attendance and examination at the inquest.—Yours truly,  
R. P. BROWN McCLELLAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your journal of March 27, "Inquisitor" asks the difference between a member and a licentiate of a college. Permit me to say—fellows and members of the College of Physicians of London are not allowed to take partners, or to make-up and charge for medicines, nor can they receive any percentage from chemists who make-up their prescriptions. The title licentiate is equivalent to a membership of Apothecaries' Hall, and granted to several practitioners who can, I believe, prescribe and make-up a bottle of physic, and charge and sue for the same, similar to a grocer who makes up a pound of tea or sugar to order, and sues for the amount under the "Tradesman's Act."—Yours truly,  
PHYSICIAN.

P.S.—I shall be glad to know if the licentiate of any other British medical college is granted on the same terms as the membership of the Royal College of Physicians of London.

[We believe the licentiate of the Dublin College corresponds in the above respects to the membership in London, and, perhaps, to that in Edinburgh. In the Edinburgh College the licentiate seems to correspond, in most respects, with the rank of the same name in London; while in Dublin there is no rank analogous to the lowest in the other two colleges. Indeed, in the Dublin College, none are members but the Fellows, who are about as numerous as the Fellows of the larger colleges at Oxford or Cambridge.—Ed. M.P. & C.]

### MEDICAL DIARY OF THE WEEK.

WEDNESDAY, APRIL 3.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.  
ST. MARY'S HOSPITAL.—Operations, 2 P.M.  
MIDDLESEX HOSPITAL.—Operations, 1 P.M.  
LONDON HOSPITAL.—Operations, 2 P.M.  
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M.  
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.  
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M.  
OPHTHALMIC HOSPITAL, SOUTHWARK.—Operations 2 P.M.  
METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—4 P.M. Meeting.  
OBSTETRICAL SOCIETY OF LONDON.—7½ P.M.: Council Meeting, 8 P.M.: Special Meeting.

THURSDAY, APRIL 4.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.  
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 1 P.M.  
LONDON SURGICAL HOME.—Operations, 2 P.M.  
ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.  
WEST LONDON HOSPITAL.—Operations, 2 P.M.  
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.  
HARVEIAN SOCIETY OF LONDON.—8 P.M. Dr. Chapman, "On Paralysis."  
Dr. C. Meredyth, "On Hygiene in Relation to Syphilis."  
ROYAL INSTITUTION.—3 P.M. Mr. Pengelly: "Antiquity of Man."

FRIDAY, APRIL 5.

WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M.  
ROYAL INSTITUTION.—3 P.M. Mr. Pengelly: "St. Michael's Mount."  
WESTERN MEDICAL AND SURGICAL SOCIETY.—8 P.M. "Narration of Cases."

### MEDICAL APPOINTMENTS.

BARON, T., M.R.C.S.E., late of St. Thomas's Hospital, has been appointed Junior House-Surgeon to the Royal Infirmary, Liverpool, vice C. Fuzey, L.R.C.P.L., appointed House-Surgeon.  
BOND, T., M.B., B.Sc.Lond., F.R.C.S., has been appointed Surgeon to the A Division of Police, Hon. Surgeon to the Royal Humane Society (St. James's-park District), and Civil Examining Surgeon to the Royal Marine Recruits.  
DAVIDSON, J. H., M.D., has been appointed Assistant Medical Officer to the Cheshire Lunatic Asylum, Chester, vice J. Norrish, M.R.C.S.E., resigned.  
EXELL, E., M.R.C.S.E., has been appointed Resident Medical Officer to the Eastern Dispensary, Bath, vice F. C. P. Howes, M.R.C.S.E., resigned.  
GAVIN, Michael Freeborn, M.D., L.R.C.S.I., has been appointed Assistant Oculist City Hospital, Boston, U.S. Highest number of marks by competitive examination.  
HAWKINS, J. V., M.D., has been appointed a Justice of the Peace for the Borough of Lyun.  
LUCAS, H., M.R.C.S.E., has been appointed Surgeon to the County Gaol, Huntingdon, vice M. Foster, M.D., resigned.  
MINCHIN, H., M.B., F.R.C.S.I., has been elected Professor of Botany in the Royal College of Surgeons, Ireland, vice the late Arthur Mitchell, M.D., L.K.Q.C.P.I., F.R.C.S.I.  
OXLEY, C. F., M.R.C.S., L.R.C.P.Ed., late House-Physician at Westminster Hospital, has been appointed Junior Assistant Medical Officer to the West Riding County Lunatic Asylum, Wakefield.  
PUZEY, C., L.R.C.P.L., recently Junior House-Surgeon to the Royal Infirmary, Liverpool, has been appointed House-Surgeon, vice G. B. V. Nash, M.R.C.S.E., resigned.  
ROBINSON, J., L.R.C.P.Ed., has been appointed House-Surgeon to the Cumberland Infirmary, Carlisle, vice Dr. Braidwood, resigned.  
TREMERAINE, Mr. J., has been appointed House-Surgeon to the United Hospital, Bath, vice Mr. T. D. Saunders, whose appointment has expired.  
TURNER, D., L.R.C.S.Ed., has been appointed one of the Medical Officers for the Parish of St. Mary, Islington, vice A. C. Cockerton, L.R.C.P.Ed., resigned.

### MEDICAL VACANCIES.

Birmingham and Midland Eye Hospital—House-Surgeon.  
Birmingham Borough Lunatic Asylum—Assistant Medical Officer.  
Bulth Union (Abergwessin District)—Medical Officer, vice Dr. Bloomenthal, resigned.  
Great Northern Hospital—House-Surgeon.  
Lock Hospital—House-Surgeon.  
Salford Union Workhouse—Resident Medical Officer.

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

KITCHING.—On the 20th of Jan., the wife of Thos. Kitching, M.R.C.S.E., &c., District Surgeon of Prince Albert, Cape of Good Hope, of a son.  
WILSON.—On the 10th ult., at Wendover, the wife of Henry Wilson, M.R.C.S., of a son.  
RUSSELL.—On the 20th ult., at Accrington, Lancashire, the wife of Wm. Smyth Russell, M.R.C.S.E., of a son.  
WIGG.—On the 21st ult., at Southminster, Essex, the wife of Thomas Carter Wigg, M.R.C.S.E., of a daughter.  
HAMILTON.—On the 21st ult., at Lyons, the wife of R. Hamilton, F.R.C.S.E., of Princes-road, Liverpool, of a son.  
CHARTERS.—On the 22nd ult., at Croft House, Thornton, Bradford, the wife of William Charters, L.R.C.P. & S. Ed., of a son.  
SAUNDERS.—On the 25th ult., at Cuckfield, Sussex, the wife of C. E. Saunders, M.D., of a daughter.  
MADDEN.—On March 31st, of a son, Great Denmark-street, Rutland square, Dublin, the wife of Dr. Thomas More Madden, of a daughter.

### MARRIAGES.

BAILEY—DUCE.—On March 19, at St John's Church Wednesbury, T. Bailey, Esq., Surgeon, Godstone, Surrey, to Eleanor, youngest daughter of the late J. Duce, Esq., Great Stanmore.  
COGAN—DUFFIELD.—On March 16, at Brighton, J. Cogan, M.D., to Agnes, youngest daughter of the late T. Duffield, Esq.  
GRAVES—CUNNINGHAM.—On March 21, at Holy Trinity Church, Paddington, F. C. Graves, M.D., of 1, Westbourne-park-villas, to Jessie Johnstone, eldest daughter of the late C. Cunningham, Esq., Accountant, Glasgow.

### DEATHS.

BULLOCK.—On March 26, at 84, Manor-street, Chelsea, E. J. Bullock, L.R.C.P. Edin., aged 47.  
DREMMOND.—On March 21, at 62, Marine-parade, Brighton, and of 15, Westbourne-terrace, Hyde-park, H. Drummond, M.D.  
STEELE.—On March 23, at Liverpool, Elizabeth Augusta, the wife of A. B. Steele, M.R.C.S.E., aged 48.  
WOODFALL.—On March 22, at Maidstone, J. W. Woodfall, M.D., in his 57th year.

## Lectures.

LUMLEIAN LECTURES  
DELIVERED AT THE  
ROYAL COLLEGE OF PHYSICIANS OF LONDON.

By J. RUSSELL REYNOLDS, M.D., F.R.C.P.,

HOLME PROFESSOR OF CLINICAL MEDICINE IN UNIVERSITY COLLEGE,  
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, AND TO THE NATIONAL  
HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

## LECTURE II.

ON SOME OF THE RELATIONS BETWEEN MEDICAL AND LEGAL  
PRACTICE.

The object of the first lecture was to show that medical testimony sometimes fails of its legitimate effect because it is not scientific; that of the second lecture is to explain why and how it may fail when it is. It was shown in the former lecture that when evidence is incomplete, inaccurate, or uncertain, it does not meet the requirements of the case; the purpose of this lecture is to prove that when scientific testimony is complete, accurate, and definite, it passes beyond or through the lines of legal precedent.

The points now to be considered are those which indicate the existence of a radical difference between the tendency of scientific study and of legal practice—that of the former being to destroy artificial lines, that of the latter to create and use them. 1st—That science in all its departments is obliged to make temporary use of artificial distinctions; 2nd—That as it advances these distinctions are swept away, and new lines of difference are substituted for them; 3rd—That, together with the discovery of previously unobserved distinctions, there is that, also, of unrecognised similitude; 4th—That the tendency of scientific growth is such as to show that likeness is greater than unlikeness—that the points of distinction are relatively trivial, while those of agreement are essential; 5th—That this is true of the simple as well as of the complex sciences—true of physics and of chemistry as well as of physiology and pathology; 6th—That science being guided by a law of growth, and legal practice governed by a law of precedent or past agreement, there must be collision between them when they attempt to express or expound each other; 7th—That, resulting from the adhesion to an agreement based upon antiquated science, wrong issues must be raised in cases of medico-legal investigation; 8th—That the illustrations of this are frequent in regard of the mode of dealing with the insane, with cases of infanticide, and rape; 9th—That common sense and legal technicalities are at variance in relation to the treatment of those who are admitted to be "mad;" 10th—That the medical witness may give some information on a case from his special knowledge, but that, in the majority of instances, he does not act upon scientific, but upon common grounds; 11th—That there is no universally applicable and valuable test of insanity; 12th—That "delusions" have only a relative value, determined by the readiness with which their nature can be appreciated; 13th—That the frequently employed tests with regard to "responsibility" are unsatisfactory; 14th—That the questions of respiration and of independent life are irrelevant to the cases of infanticide, although they may be valuable in regard of the birth of an heir; 15th—That in criminal assaults the points often raised have nothing whatever to do with the guilt of the accused, or the injury inflicted upon the accuser. The object of this second lecture was thus to show that some of the reasons for dissatisfaction with the results of medico-legal inquiry are to be found in the fallaciousness of the tests to which science is submitted, and not in the nature of science itself, which, although it may and must change its ground, is ever advancing towards a more accurate appreciation and valuable application of the truth.

## Original Communications.

ON DREAMING, CONSIDERED ESPECIALLY IN  
RELATION TO INSANITY.Read before the Medical Society of the College of Physicians, Dublin,  
March 20th, 1867.

By THOMAS MORE MADDEN, M.R.I.A.,

LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN  
IRELAND, MEMBER OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND,  
AUTHOR OF AN ESSAY "ON INSANITY AND THE CRIMINAL RESPONSIBILITY  
OF THE INSANE," "ON CHANGE OF CLIMATE, A GUIDE FOR  
TRAVELLERS IN PURSUIT OF HEALTH," &c., &c., &c.

THE subject of the following communication is a branch of medical psychology, which many years ago was discussed before the former Medical Association of this college in a paper by Mr. Andrew Carmichael, read before the Association on the 6th of April, 1813, by Dr. Brooke, and printed in the transactions for that year. As, however, I purpose to treat the subject from a different point of view to that adapted by Mr. Carmichael in his "Essay on Dreaming, including conjectures on the proximate cause of Sleep," above referred to, I mention this fact merely to show that the question of dreaming, considered especially in relation to the study of insanity, seems to be a matter not unworthy of the attention of this Society, also, which now represents the former Association of the members of the College of Physicians.

In considering the nature and causes of insanity I was often struck by the close resemblance which appears to exist between the state of the mind in insanity, and in the dreaming condition. And I have now attempted to digest the notes I made on this subject during some years into regular form, in the hope of being able to contribute something to what is known concerning a very obscure branch of mental science, and one which may possibly throw some light on the nature of the morbid action in the mind which constitutes insanity.

By the majority of scientific writers, dreaming has been considered from a purely metaphysical point of view, and perhaps on that account has received less attention than it deserves from physiological and pathological inquirers, who too often seem to ignore the truth, well expressed by Reid, that—"Medical cannot be separated from moral science without essential mutilation." I know hardly any work in the English language that treats of this question in a full and satisfactory manner.

The best account of the physiology of dreaming which I am acquainted with is that contained in Sir Henry Holland's "Chapters on Mental Physiology," which, interesting and suggestive as it is, yet leaves some parts of the inquiry altogether untouched, and hardly even alludes to the diagnostic and prognostic value of the signs furnished by this condition of the mind.

I therefore hope that I may claim the indulgent consideration of the Medical Society for the following attempt to elucidate the question of dreaming as one of the most interesting problems connected with mental physiology. And I believe that I shall be able to show that this condition of the mind affords indications which, if rightly interpreted, are calculated to throw light on the diagnosis and prognosis of some of the most obscure diseases which affect mind and body.

I. VARIOUS THEORIES OF DREAMING, ANCIENT AND  
MODERN.

What a dream really is? and how and why we dream? are questions which have been investigated by some of the greatest philosophers of every age, but which, nevertheless, still remain unsolved. Before laying my own views on these questions before the Medical Society, I shall first briefly allude to some of the most remarkable theories on the subject; as even in the wildest speculations on philosophical questions we may occasionally discover some vestige of truth, or at least, may learn to avoid the errors of our predecessors.

In Homer we find the idea that—"Dreams descend from Jove."(1) Herodotus makes Artabanus tell Xerxes that "Dreams in general originate from those incidents which have most occupied the thoughts during the day."(2) Epicurus, we are told, taught that dreams were occasioned by "images" which were supposed to emanate from all material bodies, and that being of extreme tenuity these images penetrated into the mind, although the senses were closed, during sleep, and excited in the sensorium a perception, or dream, of the object from which they proceeded. This absurd idea was subsequently adopted, and amplified by Lucretius.

In the treatise "On Dreams," commonly attributed to Hippocrates, which, although its authenticity is disputed by the late Dr. Adams, is of unquestionable antiquity, being quoted by Galen, we find an exposition of the opinion of the early Greek physicians on the subject—"When the body is at rest the soul being then in a state of movement steals over the organs of the body, manages its own abode, and itself performs all the actions of the body; for the body being asleep does not perceive, but the soul being awake beholds what is visible, hears what is audible, walks, touches, is grieved, reflects, and in a word, whatever the offices of the soul and body are, all these the soul performs in sleep. Whoever then knows how to judge of all these correctly will find it a great part of wisdom."(3)

Most of the early medical writers allude to the species of dreams to which Hippocrates refers in the passage I have just cited, and which they imagined often revealed the remedy for whatever disease the dreamer suffered from.

Galen tells us that Æsculapius was supposed to assist the sick in dreams, and in them that he pointed out the proper remedy for whatever disease the patient might suffer from.(4) When Galen himself was suffering from inflammation of the diaphragm, we read that he was instructed in a dream to open a certain vein, which he did, and recovered. Also the physician Abin Zoar acquired in the same way a knowledge of the medicine, by the use of which he was cured of a severe ophthalmia. But it was among the Greeks that this idea was fully developed and formed into a regular system.

In the first volume of Sprengel's great work on the "History of Medicine," is a most interesting account of the manner in which the Greek's prepared themselves before sleeping in the temples of Æsculapius, and of the dreams with which they were visited in these places.(5)

Speaking of the uses of dreams, Jamblicus says:—"And bodies, indeed, that are diseased it heals; but properly disposes such things as subsist amongst men erroneously and disorderly. It likewise frequently delivers the discoveries of arts, the distribution of justice, and the establishment of legal institutions. Thus, in the temple of Æsculapius, diseases are healed through divine dreams; and through the order of nocturnal appearances, the medical art is obtained from secret dreams."(6) Herodian tells us that Antonius being ill, "hastened to Pergamus, in Asia, with intent to apply to Æsculapius for the recovery of his health, and there amused himself with dreams."(7) Aristophanes gives a detailed account of the rites used to invoke a dream in the temple of Æsculapius in his comedy of *Plutus*, or *Wealth* (Act iii., Scene 2nd). But if, notwithstanding these rites and preparations, the patient did not dream of any remedy, we are told by Artemidorus,(8) that whatever the patient happened to dream about was considered as allegorical of the remedy. Though, as Sir Thomas Brown well observed, "A man might have been hard put to it, to interpret the language of Æsculapius, when, to a

consumptive person, he held forth his fingers; implying, thereby, that his cure lay in dates, from the homonymy of the Greek, which signifies dates and fingers."(1) Being thus vague, these dreams were interpreted by the guardians of the temples, who appear to have generally been shrewd and observant physicians. Plato's theory on this subject was, that dreams are caused by demons, or spirits, which he imagined filled the earth and air; and that some of these spirits being of good, and others of evil, natures, gave rise to corresponding dreams.(2) Wild and fanciful idea as this is, it is not a little strange to see it advocated by a very sober Scotch philosopher of the 17th century, with some slight modification. "Our dreams," says Mr. Baxter, "are promoted by separate immaterial beings." And again, he argues that "these beings lie in wait for, and catch the opportunity of the body, to represent, at the same time, something frightful to the mind."(3)

More rational than the last quoted speculation was Aristotle's opinion, which, in reality, differs very little from that supported by some modern metaphysicians. He says that every visible object makes an impression on the mind, but that this impression may remain in a latent condition, until it be called into active existence, during sleep, by motions in the brain, commenced before slumber has occurred, but continuing to operate in sleep, and giving rise to a dream, which is a "*Phantasma*" or appearance of a thing, after the object itself is removed.

In the "*Dæmonologia*" of Don Francesco Torreblanco, published in the early part of the 17th century, the opinions then prevalent on this subject are thus stated:—"The visions or dreams which occur in sleep are either to be ascribed to God, nature, or the devil. Those which are from God are distinguishable from those which are to be attributed to the devil, as we are told by Gregory the Great—'Holy men discern between illusions and revelations, and distinguish the sounds emitted, and images perceived in those visions when cast into deep sleep, so as to know those which emanate from a good spirit, and those which they suffer from (contrary) illusions.'"(4)

There have been many theories as to the moral significance of dreams, which at very remote periods of time have expressed a very similar idea, as may be seen by the following instances:—Zeno was of opinion that we might judge of our advancement in virtue from our conduct in dreams; and that if, in sleep, we discover that our minds are prone to yield to our passions, it is a clear indication that we have great need to watch over ourselves.(5) Sir Thomas Brown says the same thing in other words—"However dreams may be fallacious concerning outward events, yet they may be truly significant at home; and whereby we may more sensibly understand ourselves. Men act in sleep with some conformity unto their awakened senses; and consolations or discouragements may be drawn from dreams which intimately tell us ourselves . . . Persons of radical integrity will not easily be perverted in their dreams, nor noble minds do pitiful things in sleep."(6) The last opinion I shall quote on this point is that of probably the most philosophical medical writer of the 19th century, the late Sir Benjamin Brodie, who says:—"Dreams are, at any rate, an exercise of the imagination, and one effect of them may be to increase the activity of that important faculty during our waking hours. As they are influenced by our prevailing inclinations, so they may help us to form a right estimate of our own characters; and assuredly it would be presumptuous to say that they may not answer some still further purpose in the economy of percipient and thinking beings."(7)

I shall conclude this brief notice of the various theories

(5) Plutarch in "Life of Zeno."

(6) Sir Thomas Brown, "On Dreams." Works vol. iv., p. 357. Edition of 1835.

(7) Sir Benjamin Brodie, "Psychological Inquiries," &c. Part first, p. 168. Fourth Edition. London, 1862.

Poland, where it is common, and remained tenanted it in a peaceable manner until some of the joints accidentally came into my possession.

The specimens consisted of two fragments, which were three and a half, and five inches long when recent; they are composed of the mature joints. The animal was alive when I obtained it, the worm moving, and its muscular fibres contracting, though slowly; its colour was pale yellowish white; after being immersed in spirit, it diminished in length and breadth, and acquired a greyish yellow hue. The entozoon corresponds in all respects with the published descriptions given by Cobbold, in his work on "Entozoa." It is, therefore, needless to describe it more fully.

Dr. O'Brien Bellingham published, in the first series of the "Annals of Natural History," several papers on intestinal worms found in Ireland in men and animals, which afford a store of reliable information of great value regarding these creatures. Dr. Bellingham, who devoted years to their study, states that the solitary specimen of bothrioccephalus latus in his possession was given him by Dr. Aquilla Smith; it was found several years before when examining the intestines of a man who died in one of the Dublin Hospitals. He further says:—"I have only heard of two other instances in which it has occurred in Dublin; once it was met with by the late Dr. Macartney, and once by Dr. Graves, but I have had no opportunity of examining the specimens in either case." I have failed to discover any clue to the first of these cases; that of Dr. Graves is briefly recorded in a communication to the Pathological Society of Dublin (see *Dublin Medical Journal*, old series, vol. 17, p. 514.)

The genus bothrioccephalus, to which this worm belongs, as constituted by Rudolphi, contains few species. The greater number are parasitic, living inside fish or birds; they are rare in mammals, and very rare in reptiles. Man is infested by one of them, and we are indebted to Bremser for determining its characters and removing it from the tæniæ to which it had been erroneously referred.

## Hospital Reports.

### LONDON HOSPITAL.

STATISTICAL ACCOUNT OF ACCIDENTS ADMITTED DURING THE WEEK COMMENCING MARCH 26TH.

By JAMES ADAMS, House Surgeon.

Fractured ribs . . . . .	2
Fractured femur . . . . .	2
"    tib. and fibula . . . . .	4
"    fibula . . . . .	2

Total 325

The compound fracture of radius and ulna was a very severe accident. The patient, a little girl aged five years, had been trodden on by a horse; there was a laceration of skin about two inches in length, with a piece of the ulna about one and a-half inch in length protruding, this I removed by the bone forceps, the arm was then placed upon a splint

with the wound exposed, and the case is now progressing favourably.

Among the patients treated in the receiving room and made out-patients, a curious "run" of cases occurred. In eight consecutive days (6 days being of the preceding week, and the cases of those days being under the care of Mr. Disney Thorp, and the first two days of the week commencing March, 26th), no less than seven dislocations of the humerus occurred. Six of them were subcoracoid, and one subclenoid; reduction was effected at once in all; some by the heel in the axilla, and the others by extending the arm above the head. Chloroform was administered in two cases.

As seen by the table there were two cases of scald of the throat, both in children from drinking boiling water from the spout of the kettle; both occurred on the same day, viz.—Sunday, March 31st. One child was brought about three hours after the accident suffering from considerable difficulty in breathing, each inspiration being accompanied by a crowing noise; the chest, however, was well filled at each inspiration, and there was no lividity of face. The child was placed in bed, and flannels wrung out in boiling water were kept applied as hot as possible to the throat until the skin became quite red. In a few hours respiration became much easier, and by the following morning the child was comparatively well.

The other child had been taken to a chemist, who had given a powder and said that the case was of no consequence, so the mother delayed bringing it until the next day; when admitted, the child appeared to be dying; the face was livid and cold, the eyes fixed, and respiration was accomplished with the utmost difficulty. I immediately performed tracheotomy, but the child sank shortly after.

### METROPOLITAN FREE HOSPITAL

Under the care of Dr. CHARLES DRYSDALE.

TINEA DECALVANS (A CASE OF COMPLETE BALDNESS, WITH REMARKS).

MARY P., age 15, was brought to see Dr. Drysdale by Mr. Sterling, house-surgeon to the hospital, February 15th, 1867. This patient was almost entirely without hair on the scalp; with the exception of about a dozen hairs on the frontal region, and one or two on other parts of the scalp, there was nothing to be seen but a downy cotton-like growth, most visible on the occipital and the parietal regions. The patient was well nourished, and though not fat, was by no means thin. Her health was good, with the exception of occasional headaches—menstruation had occurred once or twice. There were some hairs, but not many, in the regions of the eye-brows.

*History.*—She is one of a family of four children; none of her brothers or sisters have suffered from this complaint. The baldness first commenced at the age of four years in circular patches, which enlarged and at length became, after partial reappearances, as at present, total. Dr. Drysdale observed that much of the hair was irrevocably lost; but that, if the downy hairs were carefully extracted, and a parasiticide composed of Hydrargyri Bichloridi gr.j. ad. aq. ʒj., were used for some months, it was possible that some of the hairs might grow again.

Willan described, under the name of *porrigo decalvans*, a species of tinea, which Mr. Cazenave afterwards described as vitiligo, in which the latter observer confounded it with another disease, where the hairs become blanched, but do not fall. Gruby, Audouin, and others have met in this affection a vegetable parasite *microsporon*, and the illustrious observer M. Bazin, has confirmed the existence of this parasite. We may then define tinea decalvans as a parasitic disease, which affects every part of the hairy system and causes a fall of the hair, and the presence of a cotton-like down upon the part affected, caused by the presence of a fungus called *microsporon* Audouini. At first, in this disease the hair becomes dull, dry, and less glistening, and easily pulled out whilst the skin becomes pale beneath. After the fall of the

hairs, a cotton-like down is observed on the surface of the scalp, upon which down a white dust is to be observed, consisting of the parasitic growth. In a later stage of the disease, we no longer find any down, and there is atrophy of the scalp and irremediable baldness.

The disease ordinarily appears in the form of rounded patches, surrounded by healthy hair, which patches continually tend to become larger from the extension of the parasitic growth. This may go on until every hair in the body is destroyed. The cure of this disease sometimes comes on spontaneously, as in the case above cited, for a time; in certain cases it does not go further than the downy period.

This result is much favoured by pulling out the hairs and using a parasiticide, such as gr. j. of Hydrarg. Bichlor. to aquae  $\mathfrak{z}$ i. with q.s. of alcohol. This application must be made for a long time to the parts affected. The appearance of the cryptogams under the microscope is similar to that in other parasitic diseases, except that the mycelium is in greater quantity, and the spores are said to be rather smaller.

The diagnosis of tinea decalvans is rather easy. There are two pathognomonic symptoms—(1) the fall of the hair, (2) the existence of down. It need rarely be confounded with favus or tinea tonsurans, since in favus there are crusts and cups, and the hairs do not all come out; again, in tinea tonsurans the hairs are broken, and the skin is coloured brown and covered with scales. The prognosis is generally grave as far as blindness is concerned, unless vigorous means are made use of. The disease is very contagious, and Dr. Drysdale has seen three cases of it in the same family at one time. It is, perhaps, more common in children, than in adults. The treatment must consist of epilation of a large space of the hair in the vicinity of the patch, and the long application, by means of a sponge, of the parasiticide lotion above referred to. In some cases, it is extremely difficult to extract the hairs, which break easily. When the disease has come to the last stage, all treatment is useless. Mr. Erasmus Wilson and other observers in this country seem to err in believing that cases like those cited above may be caused by nervous weakness. The baldness caused by wasting diseases, such as phthisis, syphilis, fevers, and senile baldness, &c., are easily diagnosed from that which is gradually caused by well defined patches progressing, as in this patient, because unchecked by treatment, towards total baldness.

## ST. GEORGE'S HOSPITAL.

### CASE OF HERNIA.

#### Under the care of Mr. POLLOCK.

L. A., aged 46, a married woman, was admitted on January 28th, 1867, under the care of Mr. Pollock, with strangulated femoral hernia.

She stated that on the 25th, at about ten A.M., she was carrying a pail of water up stairs when she suddenly felt faint and sick, and noticed a tumour in the right groin; had never been ruptured before; ice was applied.

There is a tumour in the right groin about the size of a walnut, very tender but not painful; the skin over it is reddened, and cannot be moved over the subjacent parts, being bound down to them. There is severe pain in the abdomen with frequent, though not stercoraceous, vomiting.

At four P.M., the operation was performed by Mr. Pollock; the tissues were found thickened by inflammation; the sac was opened and found to be almost dry, containing a small quantity of semi-purulent lymph, a piece of omentum in a state of intense congestion, bordering on gangrene; and a knuckle of small intestine completely sphacelated in one part, the gangrene, however, not implicating the entire circumference of the gut; the stricture was very tight; it was divided; the omentum ligatured and cut off; the bowel stitched to the margin of the wound, and the gangrenous portion slit open; a small quantity of fecal fluid escaped. There was little or no hæmorrhage during the operation; beef-tea two pints.

Five P.M., pil. opii, gr. ij., statim. Ten P.M., rep. pil. gr. j., st.

29th: Four A.M. Rep. pil. gr. j., st.

Had snatches of sleep during the night; vomited once, and now has nausea; there is slight tenderness in left side of the abdomen, but no pain; tongue clean and moist; pulse quite weak, 80; skin cool; there is slight fecal discharge from the wound.

Ten P.M. Rep. pil. gr. j., st.

30th: A great deal of fecal matter has been discharged from the wound; patient is very weak, and is evidently sinking. Sp. vini gall.,  $\mathfrak{z}$ vi, quot; arrowroot.

31st: Died.

For the notes of the post-mortem examination we are indebted to Mr. Pick, Curator of the Museum:—

*Externally.*—The body was in good condition.

There was a sloughy wound in the right groin, two inches long.

*Thorax.*—The lungs were congested and full of blood. The bronchi contained mucus. The heart was uncontracted, the valves blood-stained, the aorta atheromatous.

*Abdomen.*—The liver was congested. The spleen rotten. The left kidney was converted into a bag of cysts, and a calculus was formed, blocking up the ureter. The small intestines in the right iliac region were intensely injected and glued to the abdominal wall. There was an opening in them which communicated with the external wound, higher up was a second opening which communicated with the abdominal cavity, the mucous membrane being more destroyed than the serous.

The pelvis contained liquid feces. It is a question whether the rupture was finally caused by tearing the intestines apart in removing them in consequence of their already weakened condition, or whether it occurred during life.

Mr. Pollock remarked that this was one of those lamentable cases in which operative interference had been too long delayed.

It was evident from the length of time that had elapsed since the first symptoms of strangulation appeared, and from the state of the integument over the tumour, that severe mischief had occurred to the strangulated intestine. The skin was bound down by inflammatory thickening to the subjacent parts, and was a clear index to what had been going on in the sac.

It was of importance to diagnose between inflamed glands, and a hernia such as the present.

In both the appearances are similar. A swelling is formed in the groin, without impulse on coughing, and covered with reddened skin. The absence or presence of vomiting and other symptoms of strangulation, would be the data on which to found the diagnosis. But if, with symptoms of strangulation, the first incision revealed suppurating glands, it would be proper to pursue the investigation, and for the surgeon to satisfy himself that a hernia did not exist elsewhere, as both might coexist in the same case. In this instance the prognosis was unfavourable; for if the patient recovered from the immediate dangers that surrounded her, and an artificial anus were established, she might die of inanition, as it was impossible to say how low down the gut had been opened.

The almost dry condition of the sac was that described by Mr. Laurence, and was due to the extreme tightness of the stricture.

## HARVEIAN SOCIETY OF LONDON.—MARCH 27.

Dr. POLLOCK, President.

### COMMITTEE FOR THE PREVENTION OF VENEREAL DISEASES.

PRESENT—Dr. Broadbent, Mr. Weeden Cooke, Dr. Chapman, Mr. Curgenvin, Dr. C. Drysdale, Mr. Gascogen, Dr. T. Fox, Mr. James Lane, Dr. Meredyth, Dr. Menzies, and Dr. Semple. The Honorary Secretaries read answers sent from several hospitals as follows:—Mr. Gascogen and Mr. James Lane's returns showed that in the Dean-street hospital there was a

daily average of 179 male and 39 female out-patients, and 16 male in-patients. The average number of female in-patients in the female Lock Hospital being 66. In the Lock Hospital of Liverpool the returns gave the number of beds as 50, and the average number of patients in hospital as 45. No out-patients are treated at the Liverpool Lock Hospital. The Dublin Lock Hospital only admits *females* with venereal diseases. A grant from Parliament enables the hospital to maintain 100 beds; there are no out-patients, and the average number of Female in-patients is 86. In a full report sent by Mr. Holmes Coote, it was stated that the total amount of venereal cases seen daily at St. Bartholomew's Hospital was, on an average, 174. Mr. Coote wished it to be understood that the worst cases come from Whitechapel, the Commercial-road, and the East of London; that accommodation for such cases was urgently needed in that quarter, as the wards of St. Bartholomew's were filled with these East-end cases. Average number of venereal cases seen daily in the surgery, 43; in out-patients' room, 44; in the wards, 75; scattered through hospital, 12; total, 174. Sloughing sores have been, according to Mr. Coote, rather frequent of late in St. Bartholomew's Hospital. The severe cases come, for the most part, from the districts east of Finsbury; the women are very poor and dirty; young girls of 12, or even younger, are sometimes in hospital. A vast number of the girls, according to Mr. Coote, are kept and dressed by old women, who take nearly all their earnings; they follow them, watch them when ill in hospital, and dismiss them as soon as they see that they are marked or scarred. The report from Guy's Hospital showed that there was a daily average of 55 venereal in-patients, there being 25 beds for males and 30 for females affected with such diseases. This gave a proportion of venereal cases to the total of surgical cases seen as one to six. No return of the number of out-patients was sent by Guy's Hospital, which was much to be regretted. The report from the Middlesex Hospital showed that there were only 11 beds for venereal patients in that large hospital. No return, unfortunately, was made of the number of venereal patients seen daily. The report by Mr. S. Chater showed that the number of venereal out-patients seen daily at the Metropolitan Free Hospital was, on an average, 20, and that the proportion these bore to the total number of surgical cases seen was as 1 to 3. There were no beds for such cases in the hospital. In Staffordshire General Infirmary there are four male and four female beds for venereal cases, and these are frequently not filled, especially the female ones. The Southern Hospital of Liverpool sends all its venereal cases to the Lock Hospital, and it appears from the report that it has neither in nor out-patients with venereal diseases. The report from Chester Infirmary shows that there are eight beds for female venereal patients, and only an average of two occupants of these beds. Very few venereal cases come to that Infirmary. In Portsmouth Hospital there are 60 beds for female venereal patients only; no venereal out-patients. The importance of the late Government examinations in improving the health of the population, as far as venereal diseases is concerned, was well shown by the two following reports:—The Government Act came into operation in October, and so much has been effected by its means that the report from Assistant-Surgeon Knight from Sheerness Garrison Hospital shows that from 1st January to 22nd March, 1867, there have been only 36 admissions for venereal disease. Aldershot, on the contrary, has not yet enjoyed this sanitary system, and the contrast is well shown in a letter from Mr. Powell, Workhouse Medical Officer of Farnham. According to this gentleman, the average number of female venereal cases in his charge has been for the last three years 22; the average deaths 8 per cent., 15 per cent. having primary sores, and 23 per cent. gonorrhœa, the remainder had eruptions, phthisis, dropsy, &c. The largest number of deaths were from consumption than dropsy. There were two large venereal wards with 18 beds, but at present a fever ward was turned into a venereal ward. No case is refused, and Mr. Powell states that at present there was less than 200 cubic feet of space for each patient. The population of Aldershot is 16,720, of whom 10,000 are military. The Contagious Diseases' Act is soon to be enforced in that spot. The writer expressed his opinion that brothels should be licensed and inspected at Aldershot, and that it should be illegal for beer-house keepers to harbour any notorious prostitutes. He describes the majority of the cases of diseases among the prostitutes there as being chronic and non-infectious.

Mr. JAMES LANE remarked that he could now account for

the fact which he had noticed for some years back, that the very worst cases of sloughing phagedæna he ever saw at the Female Lock Hospital came from the Farnham Union.

Mr. CURGENVEN remarked that 200 cubic feet of space only was certain to cause phagedæna.

The PRESIDENT remarked that, with the exception of the reports made by Mr. Coote, Mr. Lane, Mr. Gascogen, Mr. Chater, and from the Lock Hospitals of Dublin and Liverpool, the returns were very incomplete. What the Committee desired to know was, the daily number of venereal out-patients, and the relation this number bore to the total of the surgical cases seen, so as to form an idea of the spread of the disease. The question as to the advisability of extending the principle of the Contagious Diseases' Act of 1866 to the general population was then resumed. The President was of opinion that the certifying of women, when leaving hospital, as free from disease might lead to the encouragement of fornication.

Mr. WEEDEN COOKE observed that an eminent surgeon of his acquaintance was the medical officer to a brothel, and so much good had been done by his inspections that that house was much frequented by persons who heard that disease was unfrequent in it.

Dr. TILBURY FOX remarked that it was not necessary to grant any certificate of health to the prostitutes, as if the Contagious Act was carried out, the very fact of their being seen in the streets would show that they were not diseased, as otherwise they would be in the hospital.

Dr. MENZIES considered that a police registration of all prostitutes would be a most beneficial arrangement.

Mr. GASCOGEN said that such a registration already existed in the form of a blue-book called Judicial Statistics. In this there was given the number of prostitutes in London and other towns (as, for example, about 6000 in London) for the guidance of the police. He contended that prostitution could not be ignored so long as there were so many unmarried men, soldiers, sailors, and of other classes. The present way of hunting down brothels was absurd. An informer, a member of the medical profession, at present made it his business to point out all such places, and inform as to their whereabouts to the police, for which he received a reward in half of the costs. He contended that the police should be allowed to license a brothel, and see that neither the neighbours nor the inmates were annoyed, so long as they remained quiet and retired.

Mr. CURGENVEN thought that certificates should not be granted to prostitutes.

Mr. LANE said it was important that it should be known that there was already a registration of prostitutes.

Dr. C. DRYSDALE had not quite made up his mind whether to recommend that the continental system should be extended to this country in its entirety. It had great advantages, but some great evils. On the one hand it certainly, as in Paris, Nantes, Lyons, and other French towns, much lessened the severity of venereal disease; but, on the other hand, it certainly much curtailed the liberty of the female sex. Women, he thought, had never enough freedom in any country, and having very few occupations by which they could gain a living, were sometimes forced temporarily to exist by prostitution. The French police system, he thought, stamped them too firmly with this passing misfortune, and, as it was well known, that about one-fourth of the prostitutes in this country returned into the ordinary population yearly, he questioned whether registration and police supervision should be compulsory, until it had been tried voluntarily, by means of a great addition to the Lock (female) accommodation, and the giving of certificates to those infected when free from disease. He quite agreed with Mr. Gascogen, that the police should licence certain houses in retired situations as brothels, the present system was a disgrace.

Dr. CHAPMAN thought that, as far as the army and navy were concerned, the State had a perfect right to enforce any laws which would keep them in health and working order. But he contended that the continental laws for keeping back venereal disease had not been so very successful in their attempts as to warrant us in too closely imitating them. If women had any rights at all, one of them must be the right to their own persons. He thought, too, that the tendency of such legislation was to make prostitution respectable, and as this was quite opposed to all true ideas of social happiness, he thought that they should be most cautious in adopting the system of registration and police supervision of prostitutes, unless no other means should be found of diminishing the extent of venereal diseases.

Dr. T. FOX thought that the public were quite ready to adopt

the Contagious Diseases' Act of 1866, with the exception of the certificate of health to prostitutes.

Mr. LANE said that they might be examined, but no certificate of health granted. Of 200 women lately examined at Woolwich, 85 were found to be diseased.

Dr. BROADBENT, whilst allowing the necessity of being careful in destroying the liberty of women, said that we must also think of protecting the public from disease.

Dr. MEREDYTH contended that prostitutes should not be allowed, as at present, to mix with the general public in theatres and promenades.

Mr. WEEDEN COOKE also complained of the indecency of the prostitutes who rode about in Rotten-row.

Dr. CHAPMAN contended that, as long as prostitution existed, it should be allowed to be seen, not kept quiet, in order that its evils should rouse society to further efforts to diminish the amount.

Dr. SEMPLE wished to know whether it was possible to distinguish gonorrhœa in the female from leucorrhœa, as this was practically important.

Mr. LANE said it was not; and that gentleman also added that the speculum should be used in all cases of examination of suspected women, or discharges would escape notice which existed at the os uteri.

Mr. WEEDEN COOKE observed that one serious difficulty in police registration and examination lay in the nomadic character of the prostitutes.

## Foreign Medical Literature.

SELECTIONS FROM THE *NEDERLANDSCH ARCHIEF VOOR GENEES EN NATURKUNDE*,  
Deel I., 3de Aflevering, Utrecht, 1866.

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

1. *A case in which a fork was swallowed, and removed by the formation of an abscess in the epigastric region, followed by recovery*, is described by A. H. van Andel, first physician to the Asylum for the Insane at Zutphen, in the *Nederlandsch Tijdschrift voor Geneeskunde*, Tweede afdeling, eerste aflevering, p. 58.

The case was that of a lady, aged 64, who, suffering from melancholy, had, two days before her admission on the 31st of August, swallowed a silver fork. It appeared that she had for some time contemplated suicide, and her intention was, by swallowing a fork, to put an end to her life. She had before been under treatment in the institution, during which period a similar occurrence had taken place with another woman. The fork had in this instance been removed by gastrotony; soon after the operation the patient died. She had a vivid recollection of this case, and hoped that having once swallowed a fork she also would die after the operation.

In the Institution she acknowledged what she had done, and wished to be operated on. Those living in the house with her also stated that the woman had swallowed a silver fork. On examining the abdominal integuments it was found that the fork was situated in the cardiac portion of the stomach, the points being directed upwards and forwards, while the handle was located somewhat posteriorly in the pyloric portion. The patient felt little pain, but a sensation of pressure and weight in the stomach. Under the influence of rest and the use of easily digestible food she recovered. On the 6th November the points of the fork were no longer felt, but a tumour was observed in the left side of the abdomen, above and to the left of the navel. On the 10th April a superficial projection, pointing towards the integuments, made its appearance upon the tumour, which, up to that time, had been round anteriorly, the integuments being movable over it. On the 3rd May, the patient began to complain of more pain,

and the integuments over the tumour were less movable. In the course of the month of May an abscess seemed to be developed in the seat of the projection, at three fingers' breadth from the umbilicus in a sinistral and upward direction, presenting, in the early part of June, the form of a circumscribed redness with swelling of the integuments.

The abscess opened spontaneously on the 9th of June with a very small orifice, whence a small quantity of pus mixed with fluid fecal matters made its appearance. Through the fistula no part of the fork could be felt; dark brown fœtid fecal matters were constantly discharged through the opening.

On the 12th of June the four prongs of a fork appeared in two-thirds of their length, in a nearly perpendicular direction to the abdominal wall, in the immediate neighbourhood of the fistula just described, four points having shortly before become visible, while a slight pressure on the integuments was sufficient to bring the fork into view to the above-mentioned length. Careful traction and manipulation showed that the wall of the abscess, which was in direct contact around and between the prongs, hindered the removal of the whole fork. After two incisions along the prongs, the fork was without difficulty brought into view in its integrity. On extraction, the handle was in its whole length covered with dark-brown, soft, fecal matters. After having been carefully washed, the fork appeared, in consequence of the presence of sulphuret of silver, entirely coated with blackish grey, while in the course of the middle of the handle crystals of phosphate of lime had become attached.

After the removal of the fork, the patient felt much relieved. The fistula was simply dressed and kept clean, and on the 14th July was completely closed. Around it considerable infiltration was perceptible, which gradually diminished, so that the patient entirely recovered from the results of swallowing the fork.

At the close of this communication the author quotes analogous instances of swallowed forks, and shows that in such cases it is best not to be in too great a hurry to have recourse to operative interference, and that an expectant method deserves the preference. As to the route taken by the fork, he believes that it perforated the wall of the stomach after the latter had, by adhesive inflammation, become attached to the colon; that thereupon the perforation of the adherent wall, and subsequently that of the opposite wall of the colon, took place, and that finally the abdominal integuments had been perforated.

2. *Turning by the Knee*.—A proposal to improve the technical proceeding of turning by the lower extremity. By SIMON THOMAS, Professor at Leyden (*Ned. Tijdschrift voor Geneesk.*, i., 1,).

Turning by the lower extremity is almost always effected by one or both feet; this method is generally practised and recommended. In its place the author proposes another, which, in his opinion, presents unmistakable advantages—namely, *turning by the knee*.

Only in two cases is the foot more easily reached than the knee—viz., in original breech presentation, where there can be no question of turning by the lower extremity; and in head or face presentation, with coming down of one or both feet. Except in these cases, the advantages of turning by the knee are the following:—1. In every case of turning, however the fœtus be situated, and whether the uterus be strongly contracted around it or not, the introduced hand reaches a knee sooner than a foot. 2. In every case of turning we know as surely—more surely or more quickly—where we shall find a knee than where we shall find a foot. 3. The force by which the fœtus is moved acts in every case of turning more advantageously on the lower extremity, when we make it act upon the knee, than when we draw by the foot; and, moreover, we can with greater ease, and in a manner more advantageous for the child, employ great force, when this may occasionally be unavoidable in a case of difficult turning. The proceeding to be followed to reach the knee or knees need not here be given step by step. The numbers given by the author in support of his proposal are the following:—

Cases of Turning.	Mothers.				Children.						
	Operated by Simon Thomas.		Operated by other Obstetricians.		Operated by Simon Thomas.			Operated by other Obstetricians.			
	Recovered.	Died.	Recovered.	Died.	Born alive.	Still-born.	Died before delivery.	Born alive.	Still-born.	Died before delivery.	
By the knee in shoulder presentation	21	21	—	—	15	5	1	—	—	—	
By the foot in shoulder presentation	26	12	—	13	1	7	4	1	8	4	2
By the knee in head presentation	13	10	1	2	—	8	2	1	2	—	—
By the foot in head presentation	16	8	5	2	1	7	5	1	2	1	—
Total ...	76	51	6	17	2	37	16	4	12	5	2

[The practice above recommended, of turning by the knee in preference to the foot, was many years ago advocated by the late Dr. Breen of this city, in an essay on the subject, published in the fourteenth volume of the *Edinburgh Medical Journal*, and has also been described by Drs. McClintock and Hardy in their *Practical Midwifery*.—TRANS.]

## Summary of Science.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES R. C. TICHBORNE, F.C.S.L., F.R.G.S.I., &c.

[THE Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

### ON THE REDUCTION OF NITRIC ACID AND NITRATES BY ZINC.

M. TERREIL (*Bulletin de la Société Chimique*), shows that the nitric acid is not at once reduced to ammonia by nascent hydrogen, but is always converted first into nitrous acid, and that this reaction, in conjunction with permanganate of potash, may be used as a test for the presence of nitrates in water or in any other solution. He also points out that the estimation of iron by permanganate (M. Margueritte's method) is liable to error, if every trace of the nitric acid is not destroyed, before the reduction of the persalt of iron to a proto-salt (either when brought about by zinc or by a sulphite). Permanganate of potash, according to M. Terreil, completely absorbs binoxide of nitrogen, and transforms it into nitric acid, it also oxidizes nitrous and hyp-nitric acid.

### WATER OF THE DEAD SEA.

This is a favourite subject with continental chemists. M. Terreil (*Comptes Rendus*, tom. lxi, p. 1329), however, has made some analyses that are interesting from the fact, that whilst one gives the physical and chemical properties of this water at the surface, the other is taken at a depth of 300 mètres (about 150 fathoms).

	At the surface.	At 300 metres.
The density.....	1.0216.	1.2563.
Dry saline residue....	27.078.	278.135.

It will be observed that the composition of these waters, from the subjoined analyses, is very different, and that it is not merely a simple matter of concentration. The author also gives an analysis of the river Jordan, which is not inserted here.

	Water on the surface.	Water at 300 metres.
Chlorine.....	17.628	174.985.
Bromine.....	0.167	7.093.
Sulphuric Acid.....	0.202	0.523.
Carbonic Acid.....	Traces	Traces.
Sulphuretted Hydrogen	Traces	Traces.
Magnesium.....	4.177	41.428.
Calcium.....	2.150	17.269.
Sodium.....	0.885	14.300.
Potassium.....	0.474	4.386.
Ammonia.....	Traces	Traces.
Aluminium and Iron	Traces	Traces.
Silica.....	0.006	Traces.
Organic Matter.....	Traces	Traces.

### RESPIRATION.

M. von Pettenkofer and Karl Voit say that more oxygen is absorbed during sleep than during the day, whilst less carbonic anhydride is given off during the night. During labour a man exhales more carbonic acid and water than during repose (not sleep). But the amount of oxygen absorbed is the same. It appears that during sleep the oxygen is stored up in the body for several hours. The above authors state that there is the same quantity of urea secreted in working as in resting days, showing that the work of the muscles is performed without an increase in the decomposition of albuminoid substances (*notice in Chemical News*).

### SOLUBILITY OF IODINE IN TANNIN, &c.

M. Kollier states that tannin augments the solubility of iodine. One part of iodine is dissolved in 450 parts of water at ordinary temperatures, when the water contains 3.3 parts of tannin, and at a higher temperature, 1 part barely requires 240p. of water, containing a trace of tannin. A solution of sugar dissolves less iodine than pure water.

### PRECIPITANTS OF THE ALKALOIDS.

The double iodide of bismuth and potassium precipitates the alkaloids. The antimony-salt acts in the same manner, but is not so satisfactory.

The double chloride of iridium and potassium, (also rodium and potassium) precipitates the alkaloids, particularly strychnine and brucine. To extract the alkaloids from the bismuth salt, it is only necessary to treat the precipitate with an alkali, and to agitate with benzine. The following are, however, almost insoluble in benzine:—Theobromine, morphine, solanine, curarine, narceine, and berberine.

### URIC AND KYNURENIC ACID.

G. Meissner proceeds, as follows, to separate these acids, as excreted by dogs. He boils with water and carbonate of baryta, and then filters, crystallizes the barytic kyanurate from the filtrate, and separates the uric acid from the residue left on the filter, by hydrochloric acid—kynurenic acid appears wholly or partially to obliterate the murexide test for uric acid.

### ACTION OF LIGHT UPON CYANIN.

M. Schonbein suggests the use of a solution of cyanin as a photometer. He finds that the depth of colour it takes on exposure to light is in proportion to the actinic power of the light, and that the phenomenon occurs in vacuum to the same extent.—(*Foreign correspondent of the Chemical News*).

### PERCHLORIDE OF LEAD.

There exists in the chlorine series a composition corresponding to peroxide of lead Pb. O<sub>2</sub>. This substance is a perchloride and shows consequently all the characteristics of similar compounds.

The alkaline chlorides give it stability, it is inclined to unite with ether, and becomes a powerful agent of oxidation.—N. Nickel.—*Journal de Pharmacie*.

### NEW PILE. ACTION OF NITRO-MURIATIC ACID ON SILVER, BY M. ROUILLION.

A mixture composed of two-thirds hydrochloric acid, one-third nitric acid, or three-fifths of the first, and two-fifths

nitric acid will dissolve gold or platinum, but does not penetrate pure silver—chloride of silver is only formed on the surface.

This superficial chloride as soon as it is formed becomes a protecting envelope to the remaining silver, and acts as an impervious varnish to the acids of the bath so well, that the silver thus protected can remain for any time plunged in mixture without sustaining injury. That is to say, without the formation of chloride extending beyond its surface. This pile has less strength than Bunsen's, but is more constant. It deserves to be tried against the others in use at the present time.—(*Journal de Pharmacie*).

#### HIPPURIC ACID AND SUCCINIC ACID IN ANIMAL ORGANISMS.

Dr. Meissner and C. Shepard, in the examination of blood and other animal fluids for hippuric and benzoic acids, where the presence of succinic acid is suspected, rely on the solubility in absolute alcohol of the alkali and calcium salts of hippuric and benzoic acids, the corresponding salts of succinic acid being insoluble. Normal blood, at least that of herbivora, always contains succinic acid, but never contains benzoic or hippuric acids. The hippuric acid found in the urine of herbivora is first produced in the kidneys, and is not simply separated by them from the blood. There is no clue to the nitrogenised substance, which, in the body of the animal, becomes converted into hippuric acid; whatever it may be, it certainly is not urea. The observation of Lautemann, that kinetic acid becomes converted in the human body into hippuric acid, is fully confirmed by these experimenters. Wöhler's early observation, that the administration to human subjects of succinic acid causes an increase both of the normal quantity of that acid in the urine and also of the carbonic acid, without influencing the excretion of hippuric acid, is also fully corroborated.

#### ON THE PRESENCE OF PROTAGONE IN THE BLOOD.

By M. L. HERMANN.

The author has found protagone in blood. It is contained principally, if not exclusively, in the globules, especially in red globules. To obtain it, stir with ether some defibrinated blood, the clot of which divides into small pieces. Let it remain in a jar placed in hot water for some days, stirring it frequently. This operation is repeated several times with fresh ether. On cooling the ethereal liquor at 0°, it should be muddy, if otherwise, the ether is evaporated gently until there is left a considerable crystalline residue. Placed in contact with water this residue swells. The water is drained off, and then it is treated by some cold ether to extract the cholesterine. The residue presents all the properties of Mr. Liebrich's protagone (a substance supposed by him to be the chief constituent of nervous tissue from which cerebrin and myelin are developed. It was prepared by M. Liebrich from brain-substance. Composition  $C^{116} H^{291} N^4 PO^{22}$ . E. S.)

#### ON THE DINOSAURIAN REPTILES OF SOUTH AFRICA.

Professor J. H. Huxley, in a paper he read before the Geological Society, describes a portion of a right femur twenty-five and a half inches long, so that the entire femur may be safely assumed to have exceeded thirty inches in length. The peculiar form of the bone and the character and position of the trochanters leave no doubt of the Dinosaurian affinities of the reptile to which it belonged, which must have been comparable, in point of size, to its near allies, the Megalosaurus and the Tyuanodon.

#### VEGETABLE PHYSIOLOGY.

*Stomata of Leaves*.—M. M. Duchartre and Bossingault allege that the quantity of carbonic acid decomposed by the leaves of plants has no relation to the number or superficial extent of stomata. They further state that in the case of fruits the green parts decompose carbonic acid, and yet contain no trace of stomata, therefore the stomata of leaves are not the breathing organ of plants.

*The starchy matter of plants*.—A paper laid before the

French Academy by M. Arthur Gris, states, as a conclusion, that the amylaceous matter contained in plants is partly resorbed during the development of the flowers; but that this process is not continued during the development of the fruit.

*The diagnosis of the Algæ*.—Upon this subject a controversy has been going on for some time past between M. Archer of the Dublin Natural History Society and Dr. Braxton Hicks of London. "The latter contends that there are so many intermediate forms between the earlier and later stages of the development of certain plants, which are in every respect like what Mr. Archer considers adult forms, that diagnosis from the examinations of specimens alone not undergoing development is unsatisfactory."—(*P. Science Review*).

*On the maturity of plants*.—The author M. A. Beyer's experiments are in connection with the changes which occur in fruits at different periods of their growth.

He has made observations on the changes in the gooseberry from the time of its formation to that of its complete maturity.

These observations refer to the decrease of sugar, in the amount of acid liberated, to the fatty matter, the nitrogen and the ash.

His conclusions are as follows:—As maturity progresses, the proportion of water diminishes and that of solid substances increase. The quantity of sugar always increases, but the first period of maturity the fruit encloses a maximum quantity of free acid. The diminution of which, in the later period, is only perceived when the dry material is examined.

Mineral matter diminishes progressively.

The quantity of nitrogenous matter shows the same changes as that of acid.

The fatty matter continues to increase if the total of the fruit is considered, but if the calculation is made from the weight of the solid substances it has its maximum in the first period, and diminishes afterwards by degrees.

#### ON THE DÉVELOPMENT OF SMALL ACARI IN POTATOES.

M. Guerin de Menneville exhibited at a late meeting of the French Academy, some specimens of potatoes covered with acari, but which appeared to be perfectly sound. M. G. Menneville remarked that two months of wet weather had produce myriads of acari, known as *Tyroglyphus feculæ*, on the Australian, and other varieties of potato growing on the imperial farm at Vincennes.

#### THE COMPARATIVE VALUE OF THE HEN AND DUCK EGGS AS NOURISHMENT.—BY M. A. COMMAILLE.

From the analysis made by M. Commaille, the duck has always the advantage, its fertility much greater, its nourishing value more considerable. But the hen eggs, from custom are more agreeable to the taste. The white of the duck's egg is of a blue shade which is not inviting, in the other it is more gelatineous, but in many cooking and useful preparations the duck's eggs advantageously replace those of the hen.

#### TOXICOLOGY "POISONING BY STRYCHNINE."\*

This is a report written by M. M. Tardieu, Lorain, and Roussin, on the occasion of the death of a woman named Pegard. They confine themselves to a detail of the chemical analysis of the organs extracted from the corpse, and physiological experiments performed upon living animals, with the products furnished by the analysis of the body. All the organs were perfectly preserved. The experimenters having found out that they contained no mineral substance had recourse to a direct search for the vegetable alkaloids. The stomach and intestines were divided into small pieces, these, together with the liquor contained in the first organ, and the alcohol in which they had been preserved, were introduced into a large glass flask with a fresh litre of alcohol. An alcoholic solution of tartaric acid was poured in, agitating all the time, until the whole exhibited a decided acid re-action. It was then heated to a temperature of 35°C. for 24 hours, agitating frequently. The mix-

\* *Annales d'hygiène publique et de médecine légale and Journal de Pharmacie.*

ture was thrown upon a straining cloth, and the residue treated twice with fresh quantities of alcohol, and finally the liquors were mixed and filtered through paper. Then liquors were afterwards evaporated at a temperature of about 40°.

The syrupy residue procured by the above operation, was diluted with twice its volume of distilled water, and again filtered. A concentrated solution of tannin was then added as long as any precipitate was thrown down, and the deposit separated from the supernatant liquor. The wet tannin precipitated was transported to a porcelain dish, and decomposed with a milk of pure "hydrate of lead." This was treated with alcohol, and after a digestion of an hour it was allowed to deposit. The supernatant liquor was passed through a filter, and the residue treated with a fresh portion of alcohol.

On evaporating the filtrates there remained a residue slightly coloured, of the consistency of honey, alkaline to litmus paper—having a taste partially bitter and partially saline. Some experiments made upon this residue to determine the presence of strychnine by the ordinary test for strychnine were without any results. Some physiological experiments were then tried with this residue. Six drops of a solution, prepared by dissolving 5 centigramms of the extract in 3 centimetres of acidulated water, were ingested into the cellular tissue of the abdomen, and back of a frog.

A similar operation was made on a second frog with a solution of hydrochlorate of strychnine prepared for the purpose. The experimenters observed all the symptoms of poisoning by strychnine in both frogs. Intense tetanic stiffness, contraction of the fore-legs, trembling of the breast, and convulsions of the stomach, and relaxation of the body. After these two experiments they extracted the strychnine from the residue by the following means:—The residue was diluted in 1000 cubes of distilled water, dissolved by three drops of pure hydrochloric acid, and heated at 50°. It was filtered, and then precipitated by a solution of iodide of potassium and mercury. This deposit washed by decantation was then treated by a small quantity of sulphide of ammonium, which determines the formation of an abundant black precipitate of sulphide of mercury. The residue was dried until all sulphurous smell had disappeared, and was then boiled with repeated doses of pure alcohol at 85°, they evaporated to dryness the filtered alcoholic liquors in a dish, and dissolved in some centimetres of acidulated water the white crystalline and very bitter residue. On adding to this solution a slight excess of a concentrated solution of carbonate of potassa, and then five centimetres of chloroform, treating with a second quantity of chloroform, agitating, and again separating, the bitter principal was extracted. The chloroformic solution were then evaporated to dryness at a gentle heat. There remained a residue crystalline, white, and extremely bitter, alkaline insoluble in water and soluble in alcohol. A small quantity of this residue gave an intense violet colour with sulphuric acid, and bichromate of potash, and was not coloured by sulphuric or nitric acid. A solution of the residue in hydrochloric acid gave a yellow crystalline precipitate with chloride of gold, and with chlorine, a cloudy white precipitate. Strychnine was recognised by the above reactions, whilst a hydrochloric acid solution of the crystals prepared from the poisoned woman on injection under the cellular tissue of a frog gave results similar to those of the first experiment.

The following important papers have appeared in the journals and periodicals within the last month:—

"On the Basicity of Tartaric Acid." By W. H. Perkins.  
"On the Tritration of Compound Ethers." By J. Wanklyn.

Both these papers appear in the journal of the Chemical Society for March. Prof. Wanklyn estimates the compound ethers by digesting them at a moderate temperature with an excess of a standard solution of potash, and then estimating the excess of caustic potash left. The difference shows the amount of compound ethers present. Most of the ethers are, according to Prof. Wanklyn, easily decom-

posed. Mr. Herbert McLeod, in the same journal, describes a new form of aspirator. The advantages of this aspirator consists in an arrangement by which the quantity of gas can be measured.

"On Vapour Density." By M. Cahours *Comptes Rendus*. LXIII. 14.

M. Deville, on the same subject, p. 18.

In the *Bulletin de la Société Chimique*, for February, will be found five papers from the pen of the indefatigable M. Berthelot, including one "On a New Mode of Making Oxalic Acid, and its Homologues." This consists in acting upon acetylene by permanganate of potash.

M. Wurtz, in the same journal, describes a new class of "Compound Ureas and Compound Ammonias."

Cosmos, of the 16th January, contains an interesting account of M. Gaffield's "Experiments on the Action of Solar Light upon Coloured Glass."

M. Siemens and Dr. Wheatstone have, within a few days of each other, communicated papers containing most important observations, which are almost exactly similar. It is frequently the case that some of our most valuable discoveries are thus simultaneously brought forward by different observers.

M. Siemens' paper is termed "On the Conversion of Dynamical into Electrical Force without the aid of Permanent magnetism."—Received February 4th, 1867.

Prof. Wheatstone's is "On the Augmentation of the Power of a Magnet by the reaction thereon of currents induced by the Magnet itself."—Received February 14th.

In the latter note the author says, "I intend to show that an electro-magnet, if it possess at the commencement the slightest polarity, may become a powerful magnet by the gradually augmenting currents which itself originates.

M. Stas' papers, in connection with the atomic weights, &c., are being translated in the *Chemical News*. The present memoir is "On the determination of the Quality of Silvers prepared by different methods."

#### METEOROLOGY OF MARCH, 1867.

THE past month has presented a series of phenomena of a more than usually interesting nature, besides which its severity has been greater than has been experienced for upwards of half a century. An analysis of the weather during so inclement a period, cannot but interest the profession, forming as it does a point from which may be viewed the prevailing diseases of the season.

Mr. R. H. Allnatt, whose labours we have on a previous occasion referred to, has published an epitome of his daily observations taken on the south-west coast of England, from which we extract the following paragraphs:—

Cloud.—The cloud modifications of the month were not greatly varied, nor did they assume the beautiful forms and gorgeous hues which sometimes characterize violent atmospheric fluctuations. The predominant combination was that of the cirro-cumulo-stratus, true rain-cloud, or nimbus, which existed on twenty days. No day was purely clear and cloudless, but the sun shone almost without intermission on three or four occasions which are marked by light cumulus, or cirro-cumulus.

Wind.—Violent and disastrous gales sometimes attained the force of hurricanes. On the 1st, a strong N.E. or polar wind blew until the morning of the 5th, when it moderated under the adverse conditions of decreased atmospheric tension and increased temperatures. On the 12th a cold high paroxysmal N.E. wind sprang up, and continued, with one day's intermission, till the 17th, on the evening of which it gathered strength and burst into a tremendous hurricane, which culminated on the 18th at six A.M., after which it gradually died away, having produced a series of wrecks along the line of the British coasts. On the 21st, at 8 P.M., another polar gale raged, of sufficient force to cause disasters at sea, and continued till the early morning of the 20th, when it was succeeded by heavy rainfall, great increase of temperature, atmospheric saturation, and a dead calm. On the evening of the 24th a high squally wind came from S.W., which persisting a few hours, ended in heavy

rainfall. The following day, the 25th, a strong equatorial gale visited the Irish coasts, and accounts again reached us of casualties at sea. These high gales were interspersed with minor winds of mitigated force, which on several occasions sprang up at midnight and died away in the early morning.

Barometer.—Throughout the violent atmospheric vicissitudes of the month the barometer maintained considerable steadiness of action. Its range was from 29.25in. to 30.75in., which is exactly one inch and a-half. The diurnal oscillations were frequent, but generally limited in extent. Once in the twelve hours on the 17th atmospheric tension diminished upwards of 4-10ths, but this was an isolated case, and was by far the largest amount of variation within so limited a period which occurred during the month. It coexisted with wind and heavy rainfall.

Thermometer.—The unseasonable amount of cold which prevailed at intervals in the western parts of England, and the comparative immunity of the eastern portions, have suggested an important solution in the possible deflection of the Great Gulf stream and the impact of the Arctic current. The latter effect may perhaps have been produced by the impediment offered to its usual channel by icebergs of unwonted magnitude in the Arctic regions, which, by diverting the current, threw it upon the western coasts. In the absence of demonstrative facts the theory is, at all events, plausible.

From the 1st to the 7th, inclusive, the day temperature ranged from 34 to 40 deg., making a variation of 6 deg., and the night from 29 to 35 deg., constituting also a difference of 6 deg. Mean day, 33.4 deg.; night, 31.1 deg. The night temperature was therefore 2.0 deg., and the day 4 deg. below their acknowledged means.

From the 8th to the 14th the day temperature ranged from 31 to 33 deg., and the night from 28 to 30 deg. The mean day rose to 37.1 deg., and the night to 35 deg., which is still considerably below the recognised average.

From the 15th to the 21st day temperature varied from 34 to 38 deg. The mean was 35.4 deg.; 5 deg. below the standard. The night ranged from 28 to 33 deg., the mean being 33, or exactly corresponding to the average nocturnal value.

From the 22nd to the end of the month temperatures increased, and registered 1 deg. above the average.

Rainfall.—The amount of water from heavy rains and widespread snowstorms has been enormous, and will, it is computed, gauge for the whole area of England an excess little short of 4in. March is generally a dry month, the mean rainfall being a fraction only above 2in. Last year there was a deficiency of 0.18in. In the past month the fall has been 5.17in., which exhibits an excess of 3.09 in. above the usual average. This, be it remembered, is the computation on the S.W. coast, where comparatively little snow falls, but in the north and in some districts still further west it attained an immense depth. In Bristol, for instance, Dr. Burder states that the combined amount from successive snow falls measured 8in. It is therefore a very moderate calculation which sets the gross excess of the month at 400 tons per acre for the whole of England.

Ozone.—The deficiency of this allotropic agent is remarkable, and has persisted more or less for some months. From the 25th, however, as will be seen by the table, the ozonoscopes have manifested signs of returning reaction.

Hygrometer.—The hygrometric conditions of the air were, of course, influenced by the persistent rainfalls, but they, nevertheless, maintained a fair average balance of dryness. On three days complete saturation occurred.

Thus it will be seen that the past month has been remarkable for its high persistent winds, low atmospheric temperature, and excessive rainfall.

## THE BRITISH PHARMACOPŒIA—I.

THE new edition of the Pharmacopœia, which is so soon to be issued, has been several times alluded to in our columns, and some of its most important and novel features pointed out. As we shall, however, have to enter with considerable particularity into the work, we commence a series of reports upon it before it is actually in the hands of the Profession. This, we believe, will be found a convenience to many of our readers, and enable them, on its publication, the more readily to familiarize themselves with the work which will henceforth enter so largely into the daily routine of their professional employment. Changes in abundance they will

find—many of them great improvements—some with which they will be disposed to find fault—others apparently useless. It is desirable that as soon as the work is published it should become the only authority, and therefore such changes must at once be accepted.

We are glad that no alteration has been made in the weights and measures since the former edition. It is, however, a valuable feature of the work that some of the formulæ are so arranged that they may be prepared with English grain weights and measures, or according to the French metrical system.

The most important point to the general practitioner and student is at once to become familiar with the changes of nomenclature that have been adopted, and in order to assist in this we give in full the tables which show these alterations:—

*Substances included in the Present Edition of the British Pharmacopœia, but not in the Pharmacopœia of 1864.*

[Those printed in italics were included in one or more of the Pharmacopœias of London, Edinburgh, and Dublin.]

<i>Acetum Cantharidis.</i> (Lond.)	<i>Liquor Potassæ Effervescens.</i> (Lond. 1836.)
" <i>Scilla.</i> (Lond., Ed., Dub.)	" <i>Sodæ Effervescens.</i> (Lond. 1836.)
Acidum Carbolicum.	" <i>Zinci Chloridi.</i> (Dub.)
Adeps Benzoatus.	Lotio Hydrargyri Nigra.
Amygdala Amara.	Mistura Sennæ Composita.
Atropiæ Sulphas.	<i>Mistura Spiritus Vini Gallici.</i> (Lond.)
" Sulphatis, Liquor.	<i>Morphiæ Acetas.</i> (Lond., Edin. Dub.)
Bismuthi Carbonas.	" <i>Acetatis Liquor.</i> (Lond., Dub.)
Bismuthi et Ammoniæ Citrat- tis, Liquor.	Oleum Sinapis.
Cadmii Iodidum.	" Theobromæ.
" Iodidi, Unguentum.	" <i>Vitellus.</i> (Lond.)
<i>Cannellæ Albæ Cortex.</i> (Lond., Edin., Dub.)	<i>Oxy-mel Scillæ.</i> (Lond.)
Cerri Oxalas.	Physostigmatis Faba.
Charta Epispastica.	<i>Pilula Aloes et Ferri.</i> (Edin.)
Collodium Flexile.	" <i>Conii Composita.</i> (Lond.)
<i>Confectio Opii.</i> (Lond.)	" <i>Ipecacuanhæ cum Scilla.</i> (Lond.)
<i>Decoctum Ulmi.</i> (Lond.)	Pulvis Opii Compositus.
Emplastrum Cerati Saponis.	<i>Pyrethri Radix.</i> (Lond., Edin.)
<i>Essentia Anisi.</i> (Dub.)	" Tinctura.
<i>Essentia Menthæ Piperitæ.</i> (Dub.)	Sodæ Citro-tartaræ Effervescens
<i>Extractum Lactucæ.</i> (Lond.)	" <i>Sulphas.</i> (Lond., Edin., Dub.)

	" Quiniæ.
	" Rhei. (Dub., Edin.)

*Substances included in the British Pharmacopœia of 1864, but omitted in this Edition.*

Catechu Nigrum.	Spiritus Pyroxylicus Rectificatus.
Cocculus.	Unguentum Cocculi.

*Substances the Names of which have been Altered.*

PRESENT NAMES.	NAMES IN THE EDITION OF 1864.
Acaciæ Gummi . . . . .	Acacia.
Aconiti Folia . . . . .	Aconitum.
Ammonii Chloridum . . . . .	Ammonia Hydrochloras.
Amygdala dulcis . . . . .	Amygdala.
Anethi Fructus . . . . .	Anethum.
Anthemidis Flores . . . . .	Anthemis.
Antimonium Nigrum . . . . .	Antimonii Sulphuretum.
Armoraciæ Radix . . . . .	Armoracia.
Arniciæ Radix . . . . .	Arnica.
Bela Fructus . . . . .	Bela.
Belladonna Folia . . . . .	Belladonna.
Bismuthi Subnitras . . . . .	Bismuthum Album.
Buchu Folia . . . . .	Bucco.
Calumbæ Radix . . . . .	Calumba.
Capsici Fructus . . . . .	Capsicum.
Carui Fructus . . . . .	Carui.
Cascarillæ Cortex . . . . .	Cascarilla.
Cassiæ Pulpa . . . . .	Cassia.
Cinchonæ Flavæ Cortex . . . . .	Cinchona Flava.
Cinchonæ Pallidæ Cortex . . . . .	Cinchona Pallida.
Cinchonæ Rubræ Cortex . . . . .	Cinchona Rubra.
Cinnamomi Cortex . . . . .	Cinnamomum.
Colocynthis Pulpa . . . . .	Colocynthis.
Conii Folia . . . . .	Conium.
Coriandri Fructus . . . . .	Coriandrum.
Cuspariæ Cortex . . . . .	Cusparia.
Digitalis Folia . . . . .	Digitalis.
Emplastrum Plumbi . . . . .	Emplastrum Lithargyri.
Ferri Peroxidum Humidum . . . . .	Ferri Peroxidum Hydratum.
Ferri Peroxidum Hydratum . . . . .	Ferri Peroxidum.
Felix Mas . . . . .	Felix.
Fœniculi Fructus . . . . .	Fœniculum.
Gentianæ Radix . . . . .	Gentiana.
Glycyrrhizæ Radix . . . . .	Glycyrrhiza.
Granati Radicis Cortex . . . . .	Granati Radix.
Hæmatoxyli Lignum . . . . .	Hæmatoxyllum.
Hemidesmi Radix . . . . .	Hemidesmus.
Hydrargyri Perchloridum . . . . .	Hydrargyri Chloridum.
Hydrargyri Subchloridum . . . . .	Calomelas.
Hyoscyami Folia . . . . .	Hyoscyamus.
Kamala . . . . .	Kamela.
Kramerizæ Radix . . . . .	Krameria.
Laurocerasi Folia . . . . .	Laurocerasus.
Liquor Ammonia Acetatis Fortior . . . . .	Liquor Ammonia Acetatis.
Liquor Antimonii Chloridi . . . . .	Liquor Antimonii Terchloridi.
Liquor Cantharidis . . . . .	Linimentum Cantharidis.
Liquor Ferri Perchloridi Fortior . . . . .	Liquor Ferri Perchloridi.
Maticæ Folia . . . . .	Matica.
Mistura Gentianæ Composita . . . . .	Infusum Gentianæ Compositum.
Nectandræ Cortex . . . . .	Nectandra.
Oleum Myristicæ Expressum . . . . .	Myristicæ Adeps.
Papaveris Capsula . . . . .	Papaver.
Pareira Radix . . . . .	Pareira.
Pilula Hydrargyri Subchloridi Composita . . . . .	Pilula Calomelanos Composita.
Pilula Saponis Composita . . . . .	Pilula Opii.
Piper Nigrum . . . . .	Piper.
Plumbi Oxidum . . . . .	Lithargyrum.

Podophylli Radix . . . . .	Podophyllum.
Potassæ Prussias Flava . . . . .	Ferrocyanide of Potassium.
Pterocarpi Lignum . . . . .	Pterocarpus.
Pulvis Ipecacuanhæ Compositus . . . . .	Pulvis Ipecacuanhæ cum Opio.
Pulvis Kino Compositus . . . . .	Pulvis Kino cum Opio.
Quassia Lignum . . . . .	Quassia.
Quercus Cortex . . . . .	Quercus.
Rhei Radix . . . . .	Rheum.
Rhœadus Petala . . . . .	Rhœas.
Rosæ Caninæ Fructus . . . . .	Rosa Canina.
Rosæ Centifolia Petala . . . . .	Rosa Centifolia.
Rosæ Gallica Petala . . . . .	Rosa Gallica.
Sabinæ Cacumina . . . . .	Sabina.
Sambuci Flores . . . . .	Sambucus.
Sanguisuga Medicinalis . . . . .	Sanguisuga Officialis.
Sanguisuga Officialis . . . . .	Sanguisuga Medicinalis.
Sarsæ Radix . . . . .	Sarsa.
Sassafras Radix . . . . .	Sassafras.
Scoparii Cacumina . . . . .	Scoparius.
Senegæ Radix . . . . .	Senega.
Serpentariæ Radix . . . . .	Serpentaria.
Soda Tartarata . . . . .	Sodæ et Potassæ Tartras.
Tabaci Folia . . . . .	Tabacum.
Taraxaci Radix . . . . .	Taraxacum.
Ulmi Cortex . . . . .	Ulmus.
Unguentum Zinci . . . . .	Unguentum Zinci Oxidi.
Uvæ Ursi Folia . . . . .	Uva Ursi.
Valerianæ Radix . . . . .	Valeriani.

*Preparations the Composition of which has been Altered.\**

## REFORM OF THE SANITARY LAWS.

An influential deputation from the Council of the National Association for the Promotion of Social Science waited, by appointment, on his Grace the Duke of Marlborough, at the offices of the Privy Council, on Tuesday, the 2nd inst., with the object of representing to his Grace the difficulties and anomalies which at present attend the carrying out of the various acts in relation to Public Health. The deputation consisted of Sir J. K. Shuttleworth, Bart.; Mr. Layard, M.P.; Colonel Sykes, M.P.; Dr. Rumsey, of Cheltenham; Mr. Charles Hawkins, Dr. Lankester, Mr. James Beale, Dr. Rendle, Dr. Stewart, Dr. Archibald H. Jacob, of Dublin; Mr. T. H. Gell, Dr. Hardwicke, Captain Clode, Mr. A. Pocock, and the Rev. W. L. Clay, Secretary. The deputation was received by the Duke of Marlborough, Lord Robert Montague, and Mr. Simon, Medical Officer to the Privy Council. On the introduction of the deputation, Dr. Rendle stated to his Grace the objects which the deputation had in view. His remarks were followed by able statements from Dr. Rumsey, Dr. Lankester, Mr. James Beale, and Dr. Stewart. We regret that the great demand on our space obliges us to withhold our *resumé* of their observations till next week :-

*Memorial to His Grace the Duke of Marlborough, Lord President of Her Majesty's Most Honourable Privy Council. From the Council of the National Association for the promotion of Social Science.*

THE Council of the National Association for the promotion of Social Science desires to submit to your Grace the following considerations respecting an amendment and consolidation of the laws relating to Public Health.

These laws are numerous and diverse; and as different subjects of legislative interference arise from year to year, become more complex and more difficult to interpret and apply.

Some of the enactments are general, some local. The provisions of the latter are often of universal value and applicability, and might beneficially be introduced into the former. In other instances there are different enactments relating to the same cases, with different penalties for the same offences. For instance sec. 63 of "The Public Health Act, 1848," and sec. 2 of "The Nuisances Removal Amendment Act," 26 and 27 Vict. c. 117, intended to prevent the sale of diseased meat, and collateral in their operation, impose a penalty, the one of £10, the other of £20, in precisely similar cases. This of necessity leads to confusion.

Some important enactments are permissive; indeed this principle very extensively pervades sanitary acts of the greatest importance, and consequently they are seldom acted upon. For instance, sec. 22 of "The Nuisances Removal Act, 1855," where, when ditches, &c., are a nuisance, it is left to "the opinion of the local authority" to decide whether the nuisance requires a sewer for its abatement; and secs. 23 and 24 of "The Sanitary Act, 1866," relating respectively to the provision of means for disinfection, and of carriages for the conveyance of persons sick of infectious disorders; sec. 27 of the same act, and sec. 81 of "The Public Health Act, 1848," concerning the establishment of places for the reception of dead bodies; and sec. 52 of "The Public Health Act, 1848," with reference to compelling a proper provision of closets in factories, are all permissive.

The bodies appointed to administer Health Laws are not always identical, as it is evidently expedient that they should be. There are natural connections which ought not to be disregarded—*e.g.*, the supply of water with the removal of waste; the large with the small means of drainage. These are under diverse authorities. Without bodies of more general and uniform powers, wider districts, and highly qualified Officers of Health precluded from private practice, Health Laws cannot be made fully successful in their operation. "The Sanitary Act, 1866," constitutes sewer authorities, differing in some respects from local authorities under other statutes. The Common Lodging Houses Acts are committed to the management of the police in the metropolis, to Local Boards of Health, to Town Commissioners and Justices in other places. The appointment of analysts rests with the Court of Quarter Sessions in counties, and with the Town Council in boroughs having a separate peace jurisdiction, instead of with the usual authorities for sanitary purposes. Further, this most important appointment is seldom made, as the law merely gives a permission to appoint.

The local authorities are more or less unlearned, and for that reason require plain and specific directions. They are interested in diminishing the rates, unmindful of the probable costliness of their parsimony; and they are, therefore, frequently unwilling to act in sanitary matters, except under compulsion. They are often ignorant of the importance of sanitary precautions, and indifferent to flagrant nuisances, and to the serious consequences arising therefrom to individuals, to others beyond the offending district, and to society at large. Hence the need of a special and central department to stimulate an unwilling or inefficient local authority, to act as a Court of Appeal, to diffuse to all the knowledge obtained from districts that have no connection with each other; to protect

individuals and minorities against injustice, and, being possessed of the highest practical knowledge, to construct or sanction bye-laws and local regulations.

The Building Acts, which should at least contain sound rules for insuring due attention to health in the erection of habitations, are very deficient indeed in this point of primary importance. In some few places bye-laws are even now made to serve the purpose. It is undeniable that without some very uniform and stringent additions and alterations to Building Acts (such as that which is now being promoted by the Metropolitan Board of Works), the construction of healthy dwellings, especially for the poorer classes, acknowledged to be required on a very large scale indeed, will most deplorably fail; and the new tenements will doubtless be as bad as the old, or even worse.

The sale of unwholesome and adulterated food calls for very serious attention, and for a much more efficient law. The present law is full of difficulties and defects, is much complained of, and is almost inoperative.

While, therefore, the Acts remain so complicated and multifarious, as are those now in force, it is impossible to hope for an efficient sanitary administration; especially as the principles underlying all true sanitary law are the same, more or less applicable in the same way in all places.

On these grounds the Council earnestly submit, for the favourable consideration of the Government—

1. That the laws of Public Health require to be revised and consolidated with plain and specific enactments on sanitary matters.
2. That permissive enactments are generally taken to be permissions not to act, and that therefore the most useful provisions should be made peremptory.
3. That the constitution of sanitary authorities should be more uniform; their areas of administration more extensive; their powers and functions more comprehensive; and that some provision be made for the addition of members possessing other and higher qualifications than those now required.
4. That the inefficiency in the administration of the Health Laws by the local authorities is in part due to the absence of a central power, which could be appealed to without reference to the courts of law, and could by means of judicious advice, and, if necessary, by legal compulsion, cause the local authorities to do their duty.

INTERNATIONAL MEDICAL CONGRESS.—The Central Committee of the International Medical Congress to be held at Paris this year, being anxious for the participation of the largest number of foreign members of the Profession, have taken active steps for the organisation of delegations from all parts of the world. The Congress will commence its sittings on the 16th of August, under the auspices of the Minister of Public Instruction, and it is anticipated that the occasion will be taken by a large number of the Profession in Great Britain to visit France. In each important district a corresponding delegate has been appointed to receive the names of those gentlemen who propose being present or contributing to the transactions of the Congress. In Dublin Dr. Kidd and Dr. Archibald H. Jacob have been selected, and in Birmingham Dr. B. W. Foster, and any information in reference to the Congress will be afforded by these gentlemen, or by the General Secretary, M. Le Docteur Jaccoud, 4, Rue Drouot, Paris. Members of the profession in France are subject to a subscription of twenty francs, which is remitted in the case of all others.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, APRIL 10, 1867.

### MR. BAKER BROWN AND THE OBSTETRICAL SOCIETY OF LONDON.

THE recommendation of the Council of the Obstetrical Society of London for the expulsion of Mr. BAKER BROWN from its ranks on account of “the published matters in relation to clitoridectomy,” was brought under discussion in the Society on Wednesday evening last. The suggestion has been adopted, and Mr. BAKER BROWN is no longer a member of the Society. This result was not outside our anticipation, because the decisive course which the Council adopted indicated a strong belief on their part that they would be supported in it by a majority of the members. The Society has decided, and Mr. BROWN has been expelled. A minority of 38 members have recorded their opinions in Mr. BROWN’s favour and against the Council, and though more than two-thirds of those present have stigmatized him, still the fact remains that the condemnation is by no means unanimous, and that many voices have been raised, if not in approval of his acts, in protest against the truth of the accusations or the interpretation attached by the Council to them. The evidence has been heard, the case discussed, and the verdict recorded, and we are thus at liberty to enter briefly into a *resumé* of the charges made against Mr. BROWN as published by the Council, and of his defence lately circulated by himself. We feel the less difficulty in contrasting these two documents, because they assume the form of *ex parte* statements; one of accusation, *soi disant* unprejudiced, the other in defence, avowedly one-sided. The Council have pressed into their service not only plain statements and unvarnished facts (the only evidence, in our opinion, on which the case should have been decided), but individual *dicta*—extracts from lectures, and even long leading articles, whose only effect towards the finding of a verdict, was to parade the accusations, ignore the defence, and prejudice the conclusion. To eighteen pages of such matter

the Council add a summing up of their case, as broad an appeal for support of their policy and the condemnation of Mr. BROWN as any lawyer’s address to a jury, and wind up with a threat that a contrary vote would be considered a want of confidence, and with the matter-of-course disclaimer of personal hostility. Mr. BROWN’s manifesto endeavours to answer each paragraph *seriatim*, with what success we shall presently show, and concludes with a repartee on his own side.

Now we do not wish to follow the example of either Mr. BROWN or the Council, and we believe we give expression to the general feeling when we say that this way of treating the question is not the right one. When we were promised the published matters on which the Council grounded their recommendation of expulsion, we expected to receive a simple record of Mr. BROWN’s acts and statements, and of the considerations which proved those acts infamous, and those statements false. The Profession have nothing to do, except in their private capacity, with letters or lectures, least of all with leading articles which should have been neither written nor quoted. We can compare, without regret, our own demand for a fair trial, studiously suppressed by the Council, and reproduced by Mr. BROWN, with the wholesale condemnation dealt out by our contemporaries in advance of the legitimate enquiry, none of which occupy a fitting place in a just indictment, and we conceive that by adopting this line of argument the Council have merged their dignity as accusers in their new function as prosecutors.

The parallel extracts we have selected with much care, eliminating any matter on either side not absolutely relevant to the facts. We have simply to search for a proof of the charges, and to estimate their gravity as against so severe a punishment as that inflicted on Mr. BROWN. We append to each charge the “printed matters” put forward by the Council in respect to it, and in the parallel column Mr. BROWN’s reply. Three substantial charges are made :

Firstly—“That clitoridectomy has been performed by Mr. BAKER BROWN on married women without the knowledge and consent of their husbands, and upon both married and unmarried women without their own knowledge of the nature of the operation.”

Letter of Dr. West, published Dec. 15, 1866.

Mr. Baker Brown’s Answer.

“I know a lady, aged 53, whose youngest child was more than 20 years old, who had suffered from a painful fissure of the anus, for which she underwent the usual operation of dividing the mucous membrane of the ulcer. The surgeon who did this, without saying one word to the lady or to her husband, or hinting in any way what he was about to do, cut off her clitoris. In answer to her inquiries why some other operation had been performed in addition to that which she knew was requisite, she at length learned what had been done; and further,

“I entirely deny operating upon this patient without her cognizance. She had been under treatment for some seven years. The clitoris was cut away by her express sanction—she binding me to secrecy both from her husband and her medical attendant—for, although she may not have been acquainted with either ‘the name or nature of the vice to which she was addicted,’ yet she confessed that she was in the habit of rubbing the clitoris and labia. Moreover, the nurse can attest that she even continued this practice after the operation. That the ope-

had the humiliation of discovering that the justification was that she was assumed by the surgeon to be addicted to a vice with the very name and nature of which she was alike unacquainted."

*Letter of James Paget, Esq., to Dr. West.*

"The passage from your lectures which you propose to send for publication in THE LANCET is exactly true. With part of the facts I was personally acquainted; the rest are related just as they were stated to me by the husband of the patient, and by her usual medical attendant, who was present when her clitoris was removed, but was not consulted about the propriety of the operation. Both these gentlemen are well known to me, and are of unimpeachable integrity."

*Evidence of Mr. Peaty in case of Hancock v. Peaty.*

"I had been told that she had attempted to poison herself, and I consented to let her go to Dr. Sutherland. I agreed to pay fifty guineas a-year for her board, and four of her sisters agreed to make up the difference. I cannot say whether she was really mad or not. Speaking conscientiously, I should say not; but she was certainly strange, and I have had no experience of mad people. I never gave the smallest sanction to her being taken to Mr. Baker Brown's establishment, and I am even now in the dark as to what the operation was that was performed upon her. I wrote a most passionate letter to her sister complaining of her being subjected to such barbarous treatment.

*Letter of Mr. Baker Brown, Dec. 1, 1866.*

"In the case of women of mature age, married or unmarried, I have yet to learn that an operation may not be performed, if thought necessary, for the well-being of the patient without consulting her friends, if it be her expressed wish that it should be kept secret."

Second charge—"That Mr. BROWN amputated the clitoris entirely on his own responsibility, and without the concurrence of the patient's ordinary medical attendant who was, notwithstanding, present at the operation."

*Letter of Mr. Brown, Dec. 22, 1866.*

"When I operated in the presence of her own medical attendant, I did so entirely on my own responsibility, without communicating to him my strong reasons for so doing or in any way making him a participator in the operation."

Third charge—"That Mr. BROWN stated falsely that the London Surgical Home "was not open for the reception of females of unsound mind," while,

rations has done her good, even at this distance of time, is clear, from a report I heard but three or four days ago to the effect that, whereas before she was a confirmed invalid, now she goes about in comparative health.

"I now regret that I was induced to keep the husband in ignorance of the cause which led me to operate; but it must be remembered my position was an awkward one. When a patient has put implicit confidence in her medical attendant, and has made most painful revelations, and then begs for secrecy, it is next to impossible to refuse attention to her plea; though experience makes you feel that, should she on any subsequent occasion find it necessary to screen herself, she may unhesitatingly make a 'scapegoat' of her best friend."

*Mr. Brown's answer.*

"Mrs. Peaty was brought home by her sister, she had extreme hysteria and a mind evidently weakened, though in my opinion she was not actually insane. I explained the cause of her illness, and the nature of the operation, and then with her and another sister's full concurrence, did operate. During the whole of this time I never saw or heard of her husband, nor did I afterwards ever have any communication directly or indirectly with him. If it be asserted that I ought to have known that she was at the time insane, surely when her husband was not aware of his wife's insanity at the date of her marriage with all his opportunities of intimacy with her, I can be excused by my lesser opportunities of knowing her."

Is it customary, when a married woman calls on a practitioner, with some venereal disease, to acquaint the husband with her fault; or, if a married woman comes to you with uterine disease, is it customary to ask the husband for permission before the speculum is used and the caustic applied? But my statement extended not only to married but to unmarried women of mature age, and did not apply so much to husbands, as to friends and relations generally.

*Mr. Brown's Defence.*

In all my operations, I never shirked, and I never will shirk, taking the entire responsibility. In my opinion, a consulting surgeon is bound to do so, having regard both to the welfare of the patient and the position of the practitioner.

at the same time, the Reports, and Mr. BROWN himself recorded the admission of cases of "incipient suicidal mania, acute nymphomania, epilepsy with dementia," &c.

*Letter of Commissioners in Lunacy to Mr. Brown,*

*Mr. Brown's Defence.*

"January 3rd, 1867.

"SIR,—I am directed to transmit for your perusal the enclosed copy of a paragraph which appeared in the Times newspaper of the 15th ultimo:—

"The Commissioners will now be glad to hear from yourself, as Senior Surgeon of the Home, whether there is any and what mistake in the paragraph, or on the part of the House-Surgeon, as to the objects of the Home; and, if any mistake has arisen, whether you have taken, or intend immediately to take any, and what steps to disabuse the public mind upon the subject of this apparent violation of the Lunacy Law.

"The paragraph in the Times above referred to, and headed THE LONDON SURGICAL HOME, contained the following:—'A peculiar feature of the Home is, that, in addition to the ordinary maladies which come under the head of surgical diseases, women are received who are of unsound mind, provided that their infirmities are not hereditary or of a long duration previous to their application for admission. In it the great experiment is being made for the first time of endeavouring to cure mental diseases by surgical operations.'"

*Mr. Brown's reply to the Commissioners.*

"136, Harley-street, Cavendish-square, W.,

"January 10th, 1867.

"SIR,—I have no hesitation at once in stating, as Senior Surgeon and founder of the London Surgical Home, that the institution is not open for the reception of females of unsound mind, and in no papers or advertisements issued or published by authority has it ever been stated so. During last year, one patient, a servant of ———, was taken in as suffering from hysteria. I immediately discovered she was of unsound mind, and, as quickly as possible, had her removed to Hanwell Asylum.—I am, etc., "I. B. BROWN.

"Charles Palmer Phillips, Esq."

*Extract from Speech of Mr. Brown, in Report of the Surgical Home, for 1864.*

"Two or three years ago I mentioned here that I thought we had discovered a fact so startling that it almost made one afraid to think of it. I stated that we thought we had discovered a cure for a class of suffering hitherto regarded as perfectly hopeless. I did not allude to the particular class of disease then, but I may mention it now. It comes under the head of [Epileptic Fits and Hysterical Mania. We have had many cases brought here, which have been almost without excep-

"In relation to the correspondence with the Commissioners of Lunacy, I here repeat that, if I had been called before the Council to explain, I could have satisfied any disinterested parties that there was no want of veracity on my side, and no desire to suppress the truth. ... The London Surgical Home is no more than any other hospital in London open for the reception of persons of unsound mind, and therefore is not and never has been advertised as such by the authorities of the hospital. It is quite clear, however, that as in other hospitals, such cases may have been admitted and treated; and surely no one will deny that in every hospital in London such a thing occurs. It is one thing, however, to say that an hospital is open for the reception of cases of unsound mind, and another to say that a case is occasionally, and under urgent circumstances, admitted. It is said that I have had cases of hysterical mania in the Home; but nearly all those cases were already published in my work, and it was presumed by my solicitor that any work treating on any form of insanity had been under the supervision of the Commissioners, and it was therefore unnecessary to allude to such works in my reply."

*Letter from the Author of the paragraph which appeared in the Times:—*

"DEAR SIR,—Having seen part of the evidence on which it is sought to procure your expulsion from the 'Obstetrical Society of London,' and in which it is inferred you were virtually the author of an article which appeared in the Times of the 15th December, 1866, I write to say that I am alone responsible for the notice in question. My visit to the Home was suggested by a gentleman quite unconnected with the Institution, and was paid more out of regard to the interests of the public than of the Home or its managers. On the day immediately after the notice appeared, a communication from you was forwarded to me, in which certain erroneous observations were pointed out—viz., that only women suffering from 'nervous diseases,' and not patients of 'unsound mind,' are received into the Home. As a non-professional man, however, I did not attach such importance to these points, as to feel the necessity of making any alterations.—I am dear, sir, your obedient servant,

"THE AUTHOR."

tion cured. The fit has vanished under surgical treatment, having been proved to depend upon physical causes. And so with regard to Mania. We have had cases of Epilepsy and Catalepsy where the patient has been cut off from all social pleasures and habits, excluded from their own friends, put away to distant places, and yet, by God's mercy, we have proved them in this Institution to be curable."

"'Curability of certain forms of Insanity, Epilepsy, Catalepsy, and Hysteria in Females,' published in 1866, by Mr. Brown.

"Incipient Suicidal Mania.—Many years' gradual illness—Operation—Cure. R. P., æt. 39, single; admitted into the London Surgical Home, October 22, 1861. Several years' illness—Two months' Insanity—Operation—Cure—'I was authorised to admit her.' Acute Hysterical Mania—Operation—Cure; admitted into the London Surgical Home. Epilepsy with Dementia—Operation—Cure; admitted into the London Surgical Home. Epileptic Fits with Dementia—Operation—Cure; admitted into the London Surgical Home.—Quotations from the above work, pages, 64, 65, 70, 71, 72, 73, 79, 80."

The debate of Wednesday night has added to these accusations and replications considerations which cannot but weigh heavily in the balance of public opinion. Truly we have had more of the thunder and brimstone of a discussion forum than of the solemn conference of men anxious to believe their brother guiltless, and in the oratorical contest the fortune of battle has certainly not been with Mr. BROWN. The course of Mr. SEYMOUR HADEN'S speech, rendered eloquent by the force of his apparently honest indignation, was hardly stemmed by Dr. ROUTH'S appeal for a charitable verdict, while the defence of Mr. BROWN, with whose most painful and difficult position we can easily sympathize, offered a paltry stem to the torrent of denunciation poured upon him. We confess to a feeling of extreme disappointment at the tone of this reply, and at the absence of the most powerful defence which lay within the grasp of the accused. We trusted to have been relieved by hearing an explicit and unquestionable reply to Dr. BARNES'S challenge. "Now, I ask Mr. BROWN, who is present (there he sits), if he will say here that he never operated upon a patient without the knowledge of herself, or of her friends, or of her husband." If we could not hope that the silence which followed was due to want of self-possession or some such feeling, we should be compelled to join in spirit in the vote of the Society. But can we not appreciate the confusion of mind—the bewildering influences of the situation—the apprehension of the public stigma to come—perhaps the regret for indiscretions of the past, and join with Dr. ROUTH in his appeal for favourable consideration.

Reviewing the course adopted towards Mr. BROWN from first to last, we cannot but think that the friends of the Society will experience as much regret at it as we do. Now that the prosecution has proved successful, the consideration recurs whether it was judicious to raise the question at all. The *cloaca* has been disturbed, and its foulness or fragrance pervades, not only the Profession, but the entire public—dissensions have been introduced between brother and brother, and fed fat with the exaggerations of rivals and the general gossip—one of our most noble Societies has incurred the opprobrious precedent of acting as a public prosecutor, perhaps with no very decisive result—the public has been advertised of the suspected existence of infamous practices in our ranks—and all for what? To crush a man who, if guilty, might have been much more effectually extinguished from social position and professional practice by the individual stigma of each member; and, if innocent, ought never have had it to say that he was persecuted by a clique, or condemned by a prejudging and irresponsible tribunal.

For ourselves, we have to say that we earnestly trust our pen may never again be called upon to act in such a cause. In contending to obtain an absolutely unprejudiced judgment, and to counteract the elements of petty personal jealousy or professional rivalry, the MEDICAL PRESS AND CIRCULAR will, we hope, have escaped the taint of palliating irregularities in our profession, or coquetting with the quackery which it has never yet failed to denounce.

## Notes on Current Topics.

THE PRINCE OF WALES AT ST. BARTHOLOMEW'S HOSPITAL.—We recently announced that the heir-apparent had accepted the office of President to St. Bartholomew's. On Wednesday last His Royal Highness, accompanied by their Majesties the King and Queen of Denmark, paid a visit to the hospital, and remained in the wards about an hour and a-half. They were received by Mr. Paget, who is now the senior surgeon, owing to the retirement of Mr. Wormald and Mr. White, the treasurer. The Royal party expressed satisfaction with the arrangements for the accommodation of the patients. We cannot refrain from once more alluding to the proposed liberal changes at this ancient hospital, and repeating an earnest wish that they may be effectually carried out. It is well known that Mr. Wormald only held the position of full surgeon some five or six years, having served in the grade of assistant some forty-three years prior. Such an occurrence is not likely to be repeated. We hope it is now impossible. As to the creation of special departments, nothing decisive has transpired. It is to be hoped, however, St. Bartholomew's may lead the way. The appointment of some able men outside the existing staff could not fail to increase the efficiency of the arrangements, and give general satisfaction. Hospital men rail at special institutions. Let them then provide what

is really wanted by the profession and the public, and thus extinguish the necessity for them.

**JUSTICE AND MERCY.**—The cases of Toomer and Wager, which have both been again commented upon very freely during the week, can scarcely be passed over in silence by a medical journal. It is notorious that in the former a most severe sentence was passed and is being carried out for an alleged rape, when all the medical evidence went to show that such a crime could not have been committed. The verdict of the jury was, in fact, a complete surprise to the court and to the country. Yet Mr. Walpole has been utterly deaf to the many appeals made to him to consider the sentence. On the other hand, Wager was convicted on unmistakable evidence of, perhaps, the most thoroughly brutal wife-murder in this generation. To the surprise and indignation of the whole community, in his case the capital sentence is at once commuted. Whence this astounding inequality? The defence made by Mr. Walpole in Parliament clearly shows that he is unfit to exercise the power confided to him, and renews with ten-fold force the oft-repeated arguments in favour of a regularly constituted Court of Appeal. We cannot possibly subscribe to such a blind-fold exercise of the prerogative of mercy as this. The only excuse for leaving it in the condition in which it remains, is the supposition that the revision was conducted with that degree of common sense which commends itself to the English mind, and to the exclusion of technical quibbles. But the intricate maze of lawyer's objections, or the inconveniencies of a second trial, would be a thousand times better than the alternate severity and leniency which the Home Office has lately displayed. Convicted on faint evidence, Toomer undergoes the severest penalty, while Wager, the wife-murderer, escapes the one penalty that alone has terrors for such as he.

**WORKHOUSE TREATMENT.**—"Died from disease, destitution, and want of proper care." Such was the verdict of a jury last week on a journeyman shoemaker, who died in Greenwich Workhouse, on the night of Sunday the 10th ultimo, a night in which shelter was sadly needed, as many a reader may recollect. This poor man having been refused admission at more than one of the common lodging-houses of Deptford, sought and found a temporary lodging with a former employer. He worked for his food and shelter, but the next Wednesday was quite laid up. The following Saturday the relieving officer gave an order for the medical man to visit him. This gentleman ordered the patients' admission to the workhouse. The horses usually employed for this purpose were engaged elsewhere; so in the evening a butcher's open cart was used to convey the poor sufferer to the Union-house, about two miles distant. Arrived there, and the order presented, it was endorsed "no room," and the butcher's cart was again called into service to take the patient back to Deptford. The next day delirium set in and a straight-waistcoat was used. The evening after he was again taken in the same cart to the Workhouse and admitted, though, in order to make room for him, a patient in the lunatic's ward was removed from his bed. Three hours after his admission, the poor fellow died. Well might the coroner say it was "the most distressing case that had ever been brought under his notice." It would, however, be incomplete without some items brought out in the evidence at the inquest. It appeared that besides the house being full when this poor man was

first brought, three lunatics were waiting for admission, and two other cases had been turned back. Clearly the accommodation was insufficient for the requirements of the parish, to say nothing of the distance that many have to travel to the workhouses. It is well that under the new act these grievances are likely to be remedied. We hope soon that such cases as these which have lately too often cropped up will become impossible. In the richest country in the world, with a poor-law in full force, it is a sad comment on our boasted civilisation, for men to die of "destitution and want of proper care."

**ORDER OF THE BATH.**—We are glad to perceive that there has lately been a distribution of the most honourable Order of the Bath amongst the Medical Officers of the Army and Navy. It is a step in the right direction, for duly rewarding distinguished services in the field, but we particularly regret observing that, in the Naval Service, no Irish names appear. Whether this be due to an oversight, we are quite unable to say, but the selections have been, undoubtedly, English and Scotch. Such strange facts do leave their marks behind. Can it be that there have been no medical officers from Irish schools and colleges in the thickest of the fight, and where the fire was hottest? It cannot be this, for we could name many of our pupils who were complimented for rendering assistance to the wounded, in positions eminently dangerous, under a cannonade that was fitly described as "un feu d'euufus," and we recollect clearly names being mentioned in despatches, but we refrain from quoting them now, lest we should be suspected of personal motives while contending for principle. The omission which we are now pointing out must cause a deep prejudice in the minds of our alumni against the naval service, and the sooner such oversights are rectified, the better for its interests. Poor Cindrella's willing brothers are welcome for the posts of danger, when hard knocks are imminent, but when the danger ceases, and when C.B's. are conferred, their names are absent from the lists, for we suppose this to be one of the instances in which "No Irish need apply."

**AGRICULTURAL LABOURERS.**—It appears that in some remote parts of England, men manage to exist and bring up families on wages of seven or eight shillings per week. How on this wretched pittance they keep body and soul together, how much they spend on coal during such a winter as we have lately passed through, what they eat and drink, and wherewithal they are clothed—even in the more clement season to which we are looking forward, are questions we have no pretence of being able to solve; while, as for the many moral bearings of such a fact, we must remit them to the many excellent writers who have dwelt upon them. A remedy for this state of things has been carried out by Mr. Girdleston, the clergyman of the parish of Halberton. He has assisted the labourers in his district to move to places where wages were higher, and thus enabled not a few to better their condition. The plan has been in operation more than half a year, with uninterrupted success. This is a kind of practical philanthropy in which the Medical Profession will rejoice to join, and which we, accordingly, take an early opportunity of commending. Throughout the country it is well known that the doctor knows and deplors the hard struggles for existence of the poorest classes—perhaps even more intimately than the clergyman. He sees the consequences of poverty in many

a case of disease he is powerless to arrest, and his influence is always thrown into the balance in favour of the suffering poor. Mr. Girdleston, in his truly charitable work has had to encounter much opposition from the farmers of Halberton, who have subjected him to all the petty annoyances in their power. No doubt they cherish the same kind of feelings towards him that "Guardians of the Poor" have so often indulged towards medical officers. Like them, he can smile at their opposition and go on in the path of duty and benevolence. The farmers themselves will in time learn wisdom. If wages rise in their neighbourhood, the poor-rate will probably fall, and in an improved condition of the labourer they will find the means of an improved cultivation. In the meantime a great work will be accomplished by the mere transference of labour from an overstocked market to one where there is scarcity. Good will result to all parties. We wish Mr. Girdleston a still larger success, and imitators in every district where the same conditions exist.

**CHEMICAL TOYS.**—Dr. Divers, in a letter to the *Times*, cautions the public against the dangers of numerous toys that have lately been sold in large quantities. Pharaoh's serpents are made of sulphocyanide of mercury. Devil's tears are composed of the metal sodium. Sensation cigarettes are charged with gun cotton. Parlour lighting, sold under a variety of names, consists of pyroxilin and so forth. It would be needless for us to inform our readers of the manner in which these substances, and many others, might give rise to accidents. The public should have had sufficient warning by this time, but playing with fire has always been a favourite amusement, and we might as well protest against a new sensation as a new fashion. As to the science inculcated by these toys the less said the better.

**THE PRACTICE OF ABORTION IN AMERICA.**—The crime of child-murder on the *fœtus in utero* has, it would appear, reached so great a frequency in America, that its professors not only carry on their secret trade with a profitable impunity, but they openly advertise, in their own proper names, their readiness to perpetrate the crime, or to provide others with the means of doing so. The *Philadelphia Reporter*, of March 2nd, reprints at full length a circular extensively disseminated by a person named Newton. We cannot defile our columns with this pestilential address, but may say, briefly, that the author of it offers to send by post an instrument called the "genitive regulator," intended to effect the removal of the impregnated ovum. Here is a literal extract:—

"Our plates give full information relative to the genitive organs of the female, which are to be sold or presented to each confidentially, through the aid of the practitioner—our agent—subject always to their judgment or dictation. They show the ovum. Also, application of instrument by the female's own hand, and how the instrument comes in contact with the ovum, causing it to be removed without irritation or disagreeable sensation or detriment to health, but an absolute benefit.

\* \* \* \* \*

*"Directions for Using the Genitive Regulator.*

"Within a few hours after the cessation of the catamenial discharge, and while the os uteri is dilated, introduce the regulator and pass it carefully into the uterus and turn it a few times in order to separate the embryo umbilical, as represented in the plates; after which it will pass off as

foreign matter, leaving the person free from danger until the next period, when it should be repeated, which is done without risk or pain."

**SCHOLARSHIPS FOR NATURAL SCIENCES AT CAMBRIDGE.**—We are glad to find that Downing College offers one of its foundation scholarships, of the value of £50 per annum (with rooms and commons, making the value £90 or £100), tenable for three years, as a reward for proficiency in the Natural Sciences. The examination will begin on the 5th of June, and be open to all members of Oxford or Cambridge, who shall have passed the previous examination or the responsions, and shall not have resided more than six terms. Other scholarships are also to be competed for at the same. Natural Science forms part of the examination as well as classics and mathematics. These are open to students who have not entered at the University, that is, we believe, to all students without any restriction, provided they are not members of the University. Particulars, however, can be obtained from the Rev. W. Pike, or John Perkins, Esq., tutors of the College.

**THE "CAT."**—In spite of the many objections that have been so constantly urged to retaining the punishment of flogging in the army, Parliament has resolved that it shall not be abolished. It is undeniable that difficulties surround that solution of this question which naturally commends itself to humane men. There is something so revolting in mangling the flesh of the victim, and so many tales of horror have been inflicted upon the public, many of them unhappily too true, that we should shrink from adding to them. On the other hand, it has been very strongly urged that no other punishment holds out sufficient terror to the criminal to serve as a substitute for death, which enters so largely into foreign military codes. Abroad delinquents are shot without compunction, and with all the out-cry that has been made the British soldier is more considerably treated than that of any other country. Nevertheless, the lash, we believe, is condemned. In future it will only be inflicted by court-martial, and for the most heinous crimes. It is a fact that only a very small minority of the worst characters have been lately condemned to corporal punishment. There can be little doubt that it will be found less and less necessary as the army improves, and we trust that the use of the "cat" in time of peace will soon be scarcely known in the army. It will become intolerable for the soldier to be liable to this disgraceful punishment, except for those offences in which it is employed in other cases.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 3.

Dr. HALL DAVIS, President, in the Chair.

SPECIAL MEETING.

**THE PRESIDENT:** Gentlemen,—We are met here this evening specially, in pursuance of the notice which I read at the last meeting of the Society, to consider and vote upon a resolution which was notified at that meeting. In the first place, the resolution will be proposed by Mr. Seymour Haden, and will be seconded by Dr. Barnes; then the reply of Mr. Brown will be heard, and any other remarks from other Fellows of the Society. The ballot will be taken in the next room, and it must be distinctly understood that those gentlemen who

do not vote must be considered as voting for Mr. Brown. The vote will be according to the rule which I have referred to.

Dr. MURRAY (Hon. Sec.): The rule is this:—If, on a ballot taking place, two-thirds of the Fellows present shall vote for the removal, the President shall declare the Fellow in question removed accordingly." Therefore, those gentlemen who are present will be considered as voting.

Dr. SEYMOUR HADEN moved "That in pursuance of the resolution of the Council, notified to the Society's general meeting, March 6th, Mr. Isaac Baker Brown be and is removed from the Fellowship of the Obstetrical Society of London." Now, if it should be asked, and it will be very naturally asked, why a Fellow—like myself—who has never taken a part in any of the discussions of the Society, should come forward to move this very important resolution, I think, perhaps, the best answer can be found in that very fact that I never have taken any part in any of the discussions of the Society, and especially with regard to the question before us. I may add to that that I have positively no knowledge of Mr. Baker Brown—none whatever; that I have therefore no prejudices to blind me, nor any animosities to gratify. I think, also, it will be as well to state that I have had no better means of forming a judgment upon this case than any other Fellow of this Society. I have simply read various publications upon the subject, many of which have been contributed by Mr. Baker Brown himself, and I think I may say that upon the indictment drawn up against himself by Mr. Baker Brown, and upon that alone, I came down to the Council and moved a resolution for his expulsion. I wish to take at once upon myself the whole responsibility of moving that resolution, because I am perfectly conscious of having done it upon broad Professional grounds, and without the smallest reference to Mr. Baker Brown, or to any member of the Council whatever. We have to remember, gentlemen, what we are as the Obstetrical Society of London—we have to remember that, in choosing the particular branch of Medicine which we follow, we have constituted ourselves, as it were, a body who practise among women (because I suppose that nineteen-twentieths of us do so practise); we have constituted ourselves, as it were, the guardians of their interests; and in many cases, in spite of ourselves, we become the custodians of their honour. (Hear, hear.) We are, in fact, the stronger, and they the weaker. They are obliged to believe all that we tell them. They are not in a position to dispute anything we say to them, and we therefore may be said to have them at our mercy. We, being men, have our patients, who are women, at our mercy; and I think, under those circumstances, that if we should depart from the strictest principles of honour—if we should cheat and victimise them in any shape or way, we should be unworthy of the Profession of which we are members—(hear, hear, and applause)—and certainly unworthy of being Fellows of this Society. (Loud cheers.) Now, feeling this, and feeling the urgent necessity for some such movement as we are engaged in to-night, I think, without any breach of confidence as to what took place at the Council, I cannot do better than state what happened when I brought the resolution under their notice. I came down, as I have said, wholly on my own responsibility, having mentioned it to no one. I found the Council engaged in endeavouring in every possible way, apparently, to meet Mr. Baker Brown upon less serious grounds than those which ultimately became necessary. I sat for two hours at that Council, and became perfectly convinced that there was no way of dealing with Mr. Baker Brown except by the resolution which I have just read. It was under those circumstances that I proposed the resolution, and that the Council adopted it *nemine contradicente*. At the same time, it is only fair to the Council to state that after a couple of days' interval they, feeling the extreme importance of the measure that had been proposed to them, called another meeting of the Council actually with a view, if possible, to hear objections and to arrive at some other result. But it was impossible. After sitting for two hours more, and twenty members of the Council being present, they came to the resolution that there was nothing to be done but to expel Mr. Baker Brown. (Hear, hear, and applause.) Now, having said that I think this Society is the right place in which to bring forward the resolution, I will state what are the broad motives under which I have thought it my duty to move it. I have already stated that they are not in the least personal. The motives which have induced me to bring it forward may be included, perhaps, in what I might call the growing insensibility on the part of the profession to the in-

roads of quackery, and its consequent decline in public opinion—those are the reasons which have brought me here to-night. The quackery of former days was comparatively innocent to the quackery of the present time. It was executed, whatever it was, by mountebanks outside the camp, who blew their trumpet *extra muros*, as it were, and made bad jokes, and gathered up a few halfpence, and there the thing was at an end. But now, the quackery of the present day is dangerous in this respect, that the quack of the present day has found out that he can base his operations upon an actual legitimate professional footing. He can obtain a degree, and from that moment, if he does become a quack, he becomes a quack of the most dangerous character. I may perhaps be permitted to draw attention to at least two forms of quackery which strongly affect the Society. One of them consists in this—in the diagnosis of disease which has no existence—(applause)—in the laying of women upon their back for weeks and months together, and in daily ministrations, cauterisations, and leechings to people who have literally nothing the matter with them. (Hear, hear, and applause.) I say that that is a form of quackery certainly not rife in this Society, thank God! but a form of quackery carried on with great success by at least one, if not more, Fellows of this Society. (Hear, hear.) The other form of quackery, and the only other form which I shall think it worth while to allude to, is the one under our immediate consideration. That form consists in this, if I understand it, in the pretended cure of real disease by means which have no foundation in philosophy or in fact, and which, in addition, have more or less of a secret, unpunishable, compromising character. The plan is this: a small house is taken—this may be done by one man—some name is given to it at once. It is an "Hospital for Women," or it is a "Home," or something of that kind; it does not matter what it is as long as it contains an appeal to women. We will say in this instance it is a "Home." Then three sets of appeals are sent out in the form of circulars, and they are of this kind. One is addressed to the middle classes, principally to women; that appeal is for money. Another is sent out to the upper classes, to the titled people; that is for patronage; that is for the long list of great names, headed, in this instance, by the Princess of Wales—so little do these patrons know what they are about. That is the way in which this long list of patrons is obtained. The third appeal is to the clergy, and it is always couched in these words—"for their co-operation in the good work"—that is invariable. (Laughter and cheers.) The next thing, all being compared, is to call a general meeting—which consists, of course, of the promoter of the scheme, and a few—a very few—other people, and some weak clergyman is sure to be put into the chair—that is certain. But it is my duty to go a little further. Having made these specious promises, what wonder that some poor weak woman or even that some weaker man, should take a wife or a daughter to the Home, and place her under the promoter of this scheme? It is sure to happen; and what occurs is simply this. The patient is put under chloroform—the inducement, of course, has been enlarged upon—the operation is so very trifling; it is a mere nothing, perhaps, except the cutting of a fibre or the excision of a nerve—it is nothing. The husband remains downstairs. The patient is taken up and put under chloroform, and her clitoris cut out before she has recovered from the anæsthetic. Down comes the promoter of the scheme to the expectant victim below, invites him to write a cheque for 100 or 200 guineas, or whatever it may be before he leaves the house. Now, if he objects to this, which he is very likely to do, I do not say that he is informed, but, at all events, he is made to feel this—"your daughter," or "your wife," as the case may be, "has undergone a disgraceful mutilation because she has been given to disgraceful practices; if you can afford to tell your friends this, and to tell the man who is to marry her that she has had her clitoris cut out, and that for disgraceful practices well and good; but if you cannot afford to tell them this, I think you had better pay the money and say no more about it." (Cries of "No, no," "Oh, oh!" and great uproar.) Yes. (No, no.) What! (Cries of "No, no," "Chair," and great uproar.) Yes. The nature of this quackery is that—[interruption.] I have not said that this is done; I have said that the nature, and the end, and the aim of this particular form of quackery is an operation which is in itself a mutilation. I will not call it an operation—it is a mutilation; and it is in itself questionable, compromising, unpunishable, and therefore secret. Now, if I went so far as to say that there was no difference between that and the practice of the Messrs. Goss, or some such name, M.R.C.S.—(a laugh)—who stand between

their patient and the door, and tell their patient they will expose him unless he pays a certain fee, I should be going a little further than the facts would warrant me. I do not mean to be unfair, or to go one step beyond what the circumstances warrant; but as a fact I have positively stated that there are many women who dare not speak of this, and that Mr. Brown knows it well when he cuts out their clitoris. (Cheers.) Well, but after all the question still remaining is this—Is this quackery? I shall prove before I sit down, which will be very shortly, that Mr. Brown himself confesses it to be quackery, and in this way: he states all that I have read to you, but the end and aim of all that he states is, that he cures insanity by a surgical operation. There can be no doubt of that, and that the "Home" is of all places the best; indeed, it is the only place at which this beneficent treatment can be obtained. Very well, then, Mr. Brown has distinctly asserted that he cures insanity, in many of its forms at all events, by means of this operation. But that does not prevent his writing a letter to Phillips, the Secretary of the Lunacy Commissioners, to declare that in no papers or advertisement issued or published has it ever been stated that females of unsound mind had been operated upon, or admitted even into the Home. (Hear, hear.) Now does not Mr. Brown himself admit that what he said previously is untrue? Either he has cured these people, or the whole thing is a sham. If he has not cured them, and if it is true that they have not even been admitted into the Home—as one must believe him in something—I choose to believe that when he wrote to the Lunacy Commissioners to say that no cases of insanity had ever been operated upon, or even admitted into the Home—I choose to believe that in that single letter Mr. Brown states the truth; and therefore I think we have convicted him of quackery, and that clitoridectomy is a quackery. On the part of the Council, I think I am warranted in saying that, after all the pains they have been at, after the scrupulous pains they have taken, after the labour they have been engaged in, all for the honour and welfare of this Society, if the vote to night is adverse to them, they will be obliged to regard it as a vote of want of confidence. (Hear, hear.) They will not do less—it is impossible they can do less. Now, the point is simply this: If this meeting should support Mr. Brown, it endorses his principles, and accepts his acts. (Hear, hear.) That is the point. I entreat you to let no casuistry of Mr. Brown's, or, indeed, of any other speaker, interfere with your healthy understanding of that point. That is the point: you endorse his principles and you accept his acts if you do not support the Council to-night—(hear, hear)—and in future, Professional honour and truth will be measured by the standard that you thus deliberately set up. (Loud and long-continued applause.)

Dr. BARNES: Mr. President,—I think I never in my life rose on a more painful occasion to myself, and never have I listened to an argument more convincing to show the necessity of the steps that have been taken than the speech that we have heard from Mr. Haden to-night. Of course, it may be said—and we have had rumours about—that this movement has been started by Professional rivals of Mr. Brown. There is no motive of the kind, and I may state this, that one or two members of the Council, who may have been in personal conflict with Mr. Brown, took no part whatever in the proceedings; they were not present, or, if present, they took no part in the matter. Our opposition is directed entirely against a gross infringement of Professional honour, a most shameless and abandoned course of profligacy and falsehood; and if these things are associated with any individual, our opposition is against him, and our hostility goes no further than that. I may say in the first place that the reason why it was not thought necessary to publish these matters was, that they had already been published, and those published matters contain Mr. Brown's own replies. The charges were made distinctly by Dr. West in language which no man could mistake, and by a man of the most unimpeachable honour and integrity. Mr. Brown goes on to say, "My writings have always been addressed to the Profession"—as if he made a distinction between his writings and his other publications. Are not his speeches to those weak-minded clergymen that we have heard of, and to others that Mr. Haden has referred to, publications? Have we not had the most distinct appeals made to them? Have we not had pamphlets sent round to the Profession and speeches made containing the most disgusting particulars, circulars sent round from his own house—a thing that no Professional man that I know of has ever yet ventured to do—(hear, hear)—begging for subscriptions, and enclosing prospec-

tuses, and even enclosing this paragraph of the *Times*, with an alteration of a few words? The next point is too important to pass over. He says—"I entirely deny operating upon this patient without her cognisance." That refers to the case in which he was accused of doing this by Dr. West. Upon that point Dr. West reiterates from his own personal knowledge that it was the case, and I think Mr. Brown will hardly get out of the matter by saying that he had a private compact with his patient without the cognisance of her medical attendant or her husband, and that she "sold" him. (Sensation.) More than that, Dr. West does not base his accusation upon that point. He says—"I state this deliberately, because I know that this is by no means a solitary instance of the removal of the clitoris by Mr. Brown without the consent, without the knowledge of the patient and her friends." How does Mr. Baker Brown think to escape from that? He simply states that that most direct, most positive affirmation of Dr. West is a vague statement, not worthy to be gone into. I ask Mr. Brown here if he will deny that fact in this room—if he will say here that he never operated upon a patient without the knowledge of the patient herself, or of her friends, or of her husband? I think he dare not say it, and if he did, I think twenty men in this room would confute him on the spot. Then there is the case of Mrs. Peaty. We need not dwell very much on that point, because it is really not very important. The great reason the Council placed it in the published matter was this, that it had gone before a public court of law; it had got into all the daily papers that this form of clitoridectomy—mutilation without the knowledge of the patient or the husband—had become a matter of public scandal, and that was one reason why the Council could not pass it over—why we were compelled, in vindication of the honour of the Society, to bring it before it. But Mr. Brown cannot even make a reply without some equivocation or some indirect statement which amounts to a falsehood. He says here that the operation was performed in the usual way at the Home in the presence of her own medical man, Dr. Taylor, with whom she had resided before her marriage. Now, we have a letter from Dr. Taylor:—

"To the President of the Obstetrical Society.—Sir,—May I take the liberty of calling your attention to a mistake of Mr. Baker Brown's in Nos. 12 and 13 of his reply to the remarks of the Council of the Obstetrical Society? Dr. Brown there states that I was present at the operation performed on Mrs. Peaty as "her own medical man," thus implying that the operation was with my consent. Now, I never attended Mrs. Peaty either before or on that occasion, and my presence at the Home as a student in ovariectomy was no unusual occurrence. Indeed, I was surprised at seeing Mrs. Peaty there, not having seen her since the time of her marriage, nearly twelve months before. May I ask the favour of your making this known to the Fellows of your Society? and believe me to be, with much respect, your obedient servant, J. TAYLOR, M.D."

Dr. BARNES—Now, there was another point on which we insisted very much, because it goes to the root of all honourable professional intercourse. (Applause.) No man should venture to perform an operation in the absence or without the knowledge of the other person who is there; and yet Mr. Baker Brown attempts to justify that charge by saying, "I operated entirely on my own responsibility," for that is what he says, "and, in my opinion, a consulting surgeon is bound to do so, having regard both to the welfare of the patient and the position of the practitioner." That might be so under certain circumstances, but the cases are very different in some respects. If a medical man is in a room with another, who is the ordinary medical attendant of the patient, and who, perhaps, enjoys the patient's entire confidence, and is her personal friend as well as medical attendant; if an operation of this serious nature—mutilation, for it can be called nothing else—is to be performed, without the consent of that medical man, when it is all over, and by-and-by disappointment arises, then the patient and friends begin to find fault and consider who was in fault. She says "There was my friend, my ordinary medical attendant—why did not he protect me from this mutilation?" The medical attendant says—"It was done by Mr. Brown on his own responsibility; I had nothing to do with it." Is that an answer? I ask if any woman, or any person in the world, would accept that as an answer or a vindication of a medical man who had been deceived or compromised against his own will. (Applause.) The proper course is, it appears to me—and it must appear so to every honourable man—that if a Surgeon feels that he

is morally bound by his own convictions to carry out his own practice and his own operation, he should say so plainly to the medical attendant, and give him an opportunity of retiring, or protesting, or placing the case fairly before the friends of the patient, and leaving them to decide whose advice they will follow. The explanation with regard to the Lunacy Commissioners is one which I can hardly venture to characterize among a society of gentlemen. (Hear, hear.) I hardly know how to refer to it in terms which are sufficiently within the bounds of conventional speech and yet to do justice to the matter. Mr. Baker Brown is written to by the Commissioners of Lunacy to ask for an explanation of a paragraph that appeared in the *Times*, and he writes to them saying that this paragraph appeared without his knowledge and consent—was furnished by a person indifferent to him, and that he took means, which he hoped would be successful, to correct the mistake. Now, was there any correction in the *Times*? Was the editor of the *Times* ever written to, calling upon him to explain that the Surgical Home was not open for the reception of females of unsound mind? No the editor of the *Times* was written to by the anonymous author of this paragraph whom we do not know; he was plainly connected with the press, but he is evidently not a responsible editor of the *Times*. But whether that be so or not, the answer is given that he has taken steps, which he hoped to be successful, to correct the serious error; and he took credit with the public of having cured cases of insanity, yet, to screen himself from legal proceedings, he denies it before the Commissioners. He thinks he is safe by a sort of travesty of the plea of not guilty. A man is accused of a heinous crime, no matter what it is, and before the jury or judge he pleads "not guilty;" and Mr. Baker Brown thinks that a fiction of that kind will serve him here, because he has applied to his attorney who advises him to write and say he has had no cases of that sort in the asylum. (No, no.) I will read the letters.

Dr. BARNES—Mr. Baker Brown will allow me to say he has already made two replies—they do not agree one with the other; and he may make a third if he pleases, but I doubt, if he does, whether it will agree with the others. (Laughter.) Now, I was saying that the solicitor advises him to tell a falsehood, and he told that falsehood to screen himself from the heavy charge. For his answer was taken in that sense by the whole of the Profession and the world; and he ought then to have answered these points if he could fairly have answered them. I will say one word more before I sit down on the quotations from the medical journals, on which he insists very much. We have inserted here the leading articles from several medical journals—the *Medical Times and Gazette*, the *Lancet*, and the *British Medical Journal*; these were parts of the published matters which undoubtedly guided us in framing this charge—they were published matters long ago, before the meeting of this year. They contain distinct charges, and they were expressions of Professional and public opinion which showed us that there was no alternative but to bring this matter before the Society. That article in THE MEDICAL PRESS AND CIRCULAR insisted upon so much was published after our proceedings, therefore it was not part of the published matters, and we could not possibly have anything to do with it. I have only one word more. The Profession will judge by the voice of the Society in this matter. They cannot do otherwise. We have put ourselves forward as the exponents of Professional opinion in this matter, and as we pronounce so will be the judgment of the public; and I say that we cannot, unless we are prepared to bow our heads in shame and degradation, go on as we have been doing without speaking on the subject. (Loud applause.)

Mr. BAKER BROWN—Mr. President and Gentlemen, I am glad at last that I have an opportunity of speaking, for I think you will agree with me—all those who have not made up their minds already what to do before they have heard my reply—that never in the whole history of Medicine was such an unfair proceedings taken as has been taken by the Council in this matter. I have been charged with all sorts of offences. They have met in secret council again and again. They have never intimated to me in the slightest degree what their charges were. (Cries of oh, oh.) They have never, if you observe, called me before them to ask what explanation I could give. (Loud cries of oh, oh, chair, and confusion.) I appeal to the sense of the meeting for common fairness. (Hear, hear.) I say they have left out to-night one of their gravest charges—and why? Because my

answer completely upsets their accusation against me of want of truth. The whole of this hinges upon the neglect of the Council in investigating the subject of clitoridectomy as scientific men. Instead of examining the subject, which I challenged them to do again and again, they have neglected it, and tried to get rid of it by expelling me. Now, gentlemen, it is not a question that concerns me. It is of no moment to me whether I am in this Society or not. I repudiate the insinuation, which is as unfounded in fact as it is ungenerous of Dr. Barnes. I made nothing from the Obstetrical Society; and I should apprehend, after what has passed to-night, that it will not tend to the honour of anybody to belong to the Obstetrical Society. (Cries of oh, oh.) I say so distinctly. You have heard the mover to-night say that there are other men, Fellows in our Society, having their secret practices. Why do you not fix upon them? [A voice—One at a time. (Hear, hear, and a laugh.)] Why not cleanse your own Council of secret operations and make them pure before you attack me? I have not received fair play. If you had called me before your Council and said—"We do not think this is right—we will pass laws which we think better," while I remained a Fellow of the Society, I would have obeyed those laws or have left the Society. But if it had not been for the last meeting of the Society, what would have been the consequence? I should never have heard the charges until to-night. You would never have known what they were. They would have been mysterious charges made against me affecting my honour, and I never should have known them if my friends had not come down at the last meeting and insisted on their being published. They have been published, and you have all heard them, and are there any charges amongst them which can justify expelling a Fellow from the Society? I maintain there are not; and if I may judge from the sympathy which has been manifested for me, and from the number of letters that I have received from men whom I do not know, and whom I have never met, I believe that if you were to poll the Society by proxy papers they would be with me, feeling that I have not had common fair play as an Englishman. You never yet heard of any man being condemned without being heard. You never yet heard of any man being called a thief, a liar, or a murderer, without his being called up to state whether it was true or not. But you heard to-night from Mr. Haden, whom I have not the honour of knowing, that he made up his mind to move this motion of expulsion without ever having heard one word of my reply.

Mr. SEYMOUR HADEN: Not at all. I have read your reply.

Mr. BAKER BROWN: It was known in London a fortnight ago that you were the mover of this resolution, and you never heard my reply. I say there is not a single man—not even Dr. Barnes himself—who has been as open in his practice as I have been. There is not one man in the profession who has stood up as I have done, and shown his practice openly. Look at this "Home" which Dr. Haden has scandalised and slandered in the most shameful way possible. I say that the way in which he has described the proceedings there is untrue from beginning to end. (Mr. Haden: "No, no.") (Great uproar.) I maintain that my late colleagues in the room have all performed this operation. I maintain they will all assert that I never did the thing that I have been accused of doing; that I never went down and demanded a fee from a husband or father. There were no fees demanded at the Home. It is a gross scandal upon the Home, and upon all those gentlemen associated with me. In that Home there have been, according to the entry book, 3417 entries of medical men who have visited it in the last seven years, since its formation. I do not consider that they are the signatures of 3417 individual men, for many gentlemen have been there again and again—much oftener than they state; but if I did the thing in secret—if I had practised quackery—why should I invite all the profession to come and see me? Why should they come without an invitation? Why have they come from the north, from the south, the east, and the west—from the antipodes, from Australia, from Sidney, and Melbourne, and from every state in America—why have they come? They would not come unless they saw everything really professional. Has not my work been open? Has it been secret? I deny the charge. I have done nothing in secret. I deny the charge of untruthfulness. My writings have been as open as Dr. Barnes's have been, and as practical as his have been; and it is not true to state that I have been secret and had an object in

being secret. I have been open. I have come to the conclusion that the operation of clitoridectomy is a justifiable operation—not my operation, recollect, gentlemen, but an operation that has been practised from the time of Hippocrates, and has been mentioned by all writers since that period again and again. Why, at your own very Society's meeting there were instruments in the room, I think, of Dionis, invented on purpose for clitoridectomy. (Cries of oh, oh.)

Dr. BARNES—For circumcision.

Mr. BAKER BROWN—Clitoridectomy is nothing more nor less than circumcision. (Cries of oh, oh.) You may say oh, oh, but I maintain that clitoridectomy is neither more nor less than circumcision. (Loud laughter, hisses, and groans.) I have heard the same noises before in this room. I have heard the same noises before within ten years, when a man dared to get up and say that the speculum ought to be used. Why, look how my friend Dr. Henry Bennet was met in this room, because he dared to use a speculum in examining a woman's uterus. How did they treat him? Did not these very men try to ruin him? Did not they condemn him, and write him down? (Cries of no, no.) They did; and yet Dr. Bennet's practice has proved to be a standing practice in the profession. I say if you discuss the question whether clitoridectomy is an operation founded upon pure psychological facts, investigate it like men. Dr. Tanner brought a paper forward in a scientific, proper way, and he declared it was a question which must be considered, and which could not be passed by in the profession. I asked for a committee again and again. I asked for a committee and it was not granted. Is that the way to meet the subject? If the operation is so bad, and so unfounded in practice, then ignore it, and come to a proper determination upon it. If you, as a Society, say it is a subject which cannot be treated—it is not an operation which can be performed—then come down and say so, and if I perform it afterwards, expel me. I am no more a quack than you are, or any one in this room. I am as highly educated, and have done as honest work, as any of you have done in this room. I am not the founder of a small "Home." I founded St. Mary's Hospital, or at all events, I took the largest share in it, and this little Home that you speak of, has fifty beds in it, and it is open to the whole profession. I say you have given me no reasons. You have given me twenty pages of matter of other men's accusations, but have you put one single word in my favour in these charges? Have you put one single reply of mine to the charges made against me. Surely I know as much about the physiology of the female genitals as Mr. Haden does. Have not I done it openly. Look at St. Mary's Hospital. Who was the first that performed ovariotomy and all other operations on the female genitals publicly? I contend I was. Am I quack and a worker in secret? I scout the charge. I am an open and honest worker. I have fought the battle for the profession in a great many things—not only in ovariotomy but other things too—and have had to bear the brunt and burden of the day. There are men in this room who will continue the practice in spite of what you are doing. I know one man in a hospital says he will do it in defiance of you, and he is a Fellow of your Society, and one of your own Council is Consulting Physician to it. He is doing the very things for which you condemn me. (Name, name.) I hope the gentleman is here; he is not ashamed of it, and is able to give his name himself. I tell you as a fact. (Loud cries of name, name.) There is no confidence at all. I will give you the name if you think it necessary. I have performed this operation because I believed it to be a justifiable operation. I have done it to the best of my judgment, and in a way which I considered professional. I may err—we all may err; but if I have erred call me before you, and show me where I have erred. You have not shown me yet. I was asked to believe that there had been no injustice and no personality. Why, gentlemen, I have in my pocket a letter from a gentleman who was written to by a member of the Council to ask him to come up and vote, and his remark was, "The case must be a very bad one if it wants whippers-in." It is well known that every effort has been made by the Council to bring voters up, and they now put forth a threat, which we have heard twice repeated to-night, that if the motion is not carried the Council will resign. Surely their case must be a very weak one, and they must have a sense of injustice in their hearts towards me, if they can throw out those threats. If the case is so plain, there surely can be no need for using those extraordinary

measures against a Fellow of the Society. I published the truth; and as for matters of opinion they have quoted, and as for the Commissioners of Lunacy, I had answered the letter, and had said—"Excepting those cases already published in my book." My solicitor who advised me—for, recollect, I had internal evidence that those Commissioners were put upon me by the very parties that are mixed up with this motion—(Cries of "Oh! oh!" and "Chair, Chair.") Then you are told there was no writer of the article in the *Times*. Is a man a forger? Are we all liars, according to Dr. Barnes' statement? I never knew the gentleman until he came to ask permission to go over the Home. He is an *attache* of the *Times*. I have shown the letter to a friend of mine, and they will bear me out that he is a *bona fide* man who writes to the *Times* regularly. I did not know anything about what was going to be in the article until I saw it in the paper, and I wrote to him the next day. In my reply you will see the letter written by himself, and I will show the original to the President. I say then, sir, as an Englishman, I stand upon the rights of an Englishman, and I say that I have been prejudiced without a hearing; and I ask you to-night in this room—I put it to your consciences—whether I have done that which deserves the punishment only accorded to a malefactor, for your law never intended that a man should be expelled from the Society because of his opinions—because his opinions differed from those of the Council. If that is to be law I ask you where you will stop. If you pass a vote to-night expelling me, you must go on to other members of the Society. You must go on to members of your own Council who have been convicted of want of truth, and who have been convicted of unprofessional acts. And Mr. Haden himself, by his own showing, must go on with it, for he would not dare to say I was the man who laid the women on their backs and used the speculum, and applied the caustics, and so on. He must go on with it. Then, who are to be the judges? Are the Council to be the judges? They must clear themselves first. Where are you to stop? It is a grave Professional question, and I maintain again it is a question that will not bear the light of the open day; and I know of my own knowledge, from the amount of letters I have received from men all over the country, that I have the kind sympathy of a great many men in the Profession not in this Society. You may pass a vote condemning me to-night. I do not think you will. I do not think there are so many against me in this Society. But if you do I tell you frankly I shall not consider it a stigma, and as it will apply to myself, I am surely the best judge of what I consider a stigma, because I feel that I have not been treated honestly and fairly. (Hear, hear.)

Dr. ROBINS (of Charlotte-street, Fitzroy-square)—I have never spoken to Mr. Brown in my life, but I do feel, having listened to and watched all that has been said in this matter, I observe they are extraordinary. (Laughter.) But I cannot believe that Mr. Brown has acted in *mala fides*. I will ask the whole Obstetrical Profession has not Mr. Baker Brown given as many hostages as any other person to the Profession?

Dr. SQUIRE—As no other member of the Council has risen upon a question of fact, I, whose only merit may be that I attended every meeting of the Council, deny that Mr. Brown asked for a committee. It seems to me that the way in which the Council were forced into action was that it was published in two medical journals. I myself saw, to my great astonishment, a publication that the Council had been already asked to inquire into this matter, when the Council had received no such request; and at the next meeting of the Council we found in the meantime a letter had been sent, but withdrawn, and never came under our notice at all. And here Mr. Brown to-night, and Mr. Brown, jun., at the last meeting, say this committee had been demanded.

Dr. SAVAGE—Mr. Seymour Hayden addressed us in the most powerful manner on the part of the prosecution—(cries of "Order, order" and great uproar)—I repeat, on the part of the prosecution. But, in fact, what has been produced has been this—an abstract with everything that could possibly be turned in favour of Mr. Brown carefully abstracted from it. I do not consider that quite fair. However, Mr. Brown has had the opportunity of replying, and has sent round a circular which may be considered parallel to the one sent round by the Council, so that I have little else to say. Mr. Brown may say what he pleases. He may say he does not care. He may say it will make no difference. But I know it does make a difference.

I should be ashamed to be connected with this Society if I did not feel that if I had misconducted myself in such a manner as to deserve to be sent out of it I should forfeit my position in the profession. My object in joining the Society was simply to contribute my mite of information to the advance of obstetrical science. I cannot follow Mr. Haden in his statement of our out-of-door ethics at all. I know what we owe to each other, and that is fairness and common honesty. There has been much acrimony displayed against Mr. Brown. I am very sorry indeed that Mr. Brown undertook his own defence. I am sorry he ever uttered a word. I am very sorry indeed for Mr. Brown that he ever offered the Society an opportunity of inquiring into his conduct with regard to clitoridectomy. It had better have remained just as it was—to be estimated by the profession according to the results as they turned out from time to time.

Dr. ROUTH—I really do think, and am afraid, that Mr. Brown has damaged his cause by having spoken in the way he has done, and I am sure that there is much to say in his excuse, inasmuch as when a man is put in the very difficult, painful, and unenviable position in which Mr. Brown has been placed, if he is not listened to with that attention which he ought to be listened to, and if he is constantly interrupted—(No, no)—then, sir, that gentleman is sure to become confused, and his reply, instead of being one which will be in his favour, may be construed to be one which is just the reverse. Now, sir, I hope that in this state of facts the Society will listen to me as I endeavour to make a few observations to show why I think it would be wise in you and in the members of the Obstetrical Society generally not to carry out this severe and harsh sentence against Mr. Brown. Now, sir, in the first place, I must start with this proposition. I do not care what the press generally may say. I am now speaking in general terms as to the conduct of A., B., and C. It is perfectly well known in these days that a particular class of papers take up a particular bias of doctrine, and upon that bias of doctrine they write. I will take an instance. Supposing any one of us wanted to form an opinion on John Bright—(Question, and uproar.) I do hope, and I appeal to the Society—I stand here really with a wish to do justice towards a fellow-man who is in great distress, and I stand up here as a man, to say a word in his favour. Now, sir, I say if you wanted to form an opinion of John Bright, would you take that opinion from the *Standard*? If you wanted to form an opinion of Lord Stanley, would you take it out of the *Evening Star*? Certainly not. Why? Because those papers have peculiar doctrines, and it is part and parcel of their doctrines to oppose Mr. A., B., or C., because he holds different opinions to themselves. In the same way, I say you are not justified in taking, as grounds of justification, the opinions in the medical articles of any journal; and so far I believe that that document which has been issued by the Council has been formed in accordance with those articles. Mr. Brown has spoken in the strongest terms of Dr. West. Now, I have had the pleasure of meeting Dr. West on a great many occasions: I know he is a man whose name will be handed down to posterity as a great name in our profession. But, sir, would I pin my faith to Dr. West as to any matter of doctrine? Have I not got the right given to me, thank God! that I can always use my knowledge of right and wrong to know whether Dr. West is right or wrong? It appears to me to say that because Dr. West says such and such things are so, it does not follow, because Mr. Brown says such and such things are not so, that therefore Dr. West is right and Mr. Brown is wrong. The inference is perfectly illogical. It is said Mr. Brown went and operated upon a lady—it is stated here on the authority of Dr. West—against her consent. Now, that is a grave charge. What does Mr. Brown say? Mr. Brown said—“Yes, I did. I now see that I committed an error.” But I will ask you this. I do not talk to those gentlemen who have the experience of the world upon them, but I ask the young men of the Profession—those who are rising up—I ask those young men, if a woman came to you and told you, “I am doing such and such things—I do not want my husband to know it.” I think there are very few young men (loud cries of no, no) who would not do as Mr. Brown has done. Supposing a lady came to you and told you she was in the family-way; but, unfortunately, this lady being a married lady—I take a case that may occur and has occurred—she will tell you—she will probably let out the fact—that her child is not her husband’s. (Oh, oh, and

laughter). Now, I will ask you is it any part of your duty, having got this information, to go to the husband and say—“That wife of yours is not virtuous.” Certainly not. Now sir, I will go to another point. It is said Mr. Brown has been in the habit of cutting off the clitoris of persons without informing them of it. Now, if that be so, I will merely ask you if you had to operate upon a patient—I do not care what the operation may be—is it customary to enter into the minutiae and to describe every particular phase of the operation to the patient? (Yes, yes.) Then if it is the custom, there are very few Surgeons who keep to it. (Oh, oh, and question, question.) That is the question. It is because this goes so home in the matter that you call out question. But I know this to be the fact, and you and every one of you know it also to be a fact that very often persons are operated upon, the Surgeon giving them a general idea of what the operation may be, but not going into all the minutiae of the operation. It has been said—and the most unmeasured terms have been used—that Mr. Brown has been guilty of falsehood. Now, sir, let us look at the case exactly as it is. Let us understand what took place before the Commissioners of Lunacy. An article appears in the *Times* calling the attention of the Lunacy Commissioners to Mr. Brown’s practice. As the result of that, we find a few days afterwards that a letter is addressed to Mr. Brown, and he is asked to give his opinion with reference to certain people who have been taken into his Home and operated upon for being of unsound mind. And what is more, the House-Surgeon is brought forward, and he admits positively that sometimes people of unsound mind were taken into the Home. What does Mr. Brown say? Does Mr. Brown say that he has not taken in any cases? That is the main point, and the wisdom of the lawyer proved it so. He merely says this—“That during the past year”—those are the words—“during the past year—”

Dr. WYNN WILLIAMS—“Ever—.” (Cries of “Read, read.”)

Dr. ROUTH—“I have no hesitation in stating, as Senior Surgeon and founder of the London Surgical Home, that the institution is not a Home for the reception of females of unsound mind; and in no papers or advertisements issued or published by authority has it ever been stated so.” Now, sir, what is an institution that is open for the reception of insane persons? I really think you must look to the meaning of words. After all, we can only speak according to English. What is an institution open for the reception of insane persons? As I read it, it is a lunatic asylum, according to the plain English construction of phraseology. But it before any person you like who is accustomed to write according to orthographical rules. I maintain, as far as that is concerned, Mr. Brown is perfectly right. The authorities have never stated that that Home was open as a lunatic asylum. I do not say that altogether the thing admits of a perfectly clear interpretation, but every man, I think, would have done pretty nearly the same thing if he had fallen into the same difficulty. I say I admit that; but I do not think it is justifiable to turn round upon Mr. Brown in this way. I think the Council are in error. They ought to have rather passed a vote of censure, after full, free, and entire investigation of the question, against Mr. Brown. If they had done so, Mr. Brown no doubt would have resigned, and we should have got rid of all this annoyance which has taken place, and which has been exceedingly injurious to the Society. I do not mean to say to-night that Mr. Brown has not been injudicious, that he has not been enthusiastic, that he has not laid himself open to several of the charges that have been brought; yet, inasmuch as I believe honestly—and certainly you will admit I have as much right to my belief as any other man—that he has acted more from ignorance as to what he really meant to do or to say than from wilful malice, I feel, as a man who would wish to follow the attribute of mercy and consideration towards a fellow-man, that I should not be justified in voting against Mr. Baker Brown, and in supporting the action of the Council. Consider—and now I appeal to you all, gentlemen—the extremely unhappy position in which you are going to place Mr. Brown. Consider the injury which you do personally to the man. Is the punishment not greater than the offence? If you will not consider Mr. Brown at present, consider what he has done for science; and there is nobody here [present, not even his enemies, who will deny that he has done good in the profession. (Hear, hear.) Consider, lastly—and here I appeal to you as men of feeling—the injury you do by such a step to those who have

not erred with himself, and who are the members of his own family. Sir, I confess for my part, believing that I have the heart of a man, that I cannot bring myself to vote in favour of this motion. I cannot bring myself on this occasion to put my hand into that box against Mr. Brown. And bear this point in mind, that if we could be clean dissected, every one, there is no doubt whatever that many of us have been guilty—if not wilfully, at least by accident—of many an unprofessional act. ("Thank you; thank you.") I say, if not wilfully, nevertheless we have done it; and, under those circumstances, I should say, having in consideration the injury that you do to the man whom you wish now to ruin—(Oh, oh, no, no)—let the man that is perfectly pure and immaculate among you throw in the first ball.

Dr. TYLER SMITH—I do not think any one could repeat without grave consideration the words uttered by Dr. Routh. It appears to me the great vocation of the meeting to-night is to defend women who have been and are liable to be injured by the practices in question. There are a great number of females in London, and scattered throughout the country, who are in this case, and I may say that for the last two or three years I have never gone into the country to see a patient without having complaints of cases made to me upon this matter of clitoridectomy. There are numbers of families where the husband is annoyed, and the wife made wretched for life, by this operation having been performed with or without the consent of the patient and her husband. Then there are a number of young women upon whom this operation has been performed without the, at all events perfect, knowledge of themselves and their relatives; and these young women are in as deplorable a condition as can be imagined. If they are honourable, should any proposal of marriage come to them, the parents are obliged to tell the parties proposing that they have been mutilated, and thus they are obliged to expose themselves to the possibility of being treated as imperfect persons. Now, I think our sympathy should be with women in this position and their friends, and not with those who are instrumental in producing such unhappy results. It appears to me that the two main matters which we have to consider are the performance of the operation upon married women without the consent of their husbands, and upon unmarried women without the knowledge of their friends and of the patients themselves. Now it is substantially admitted by Mr. Brown in the documents we have before us that this is his notion of right practice, and that he does not shrink from this responsibility. I say that we, the Council, have not entered into the question of clitoridectomy in itself; we have avoided this matter; we have confined ourselves to the consideration of the questions in ethics arising out of the mode in which it has been performed. (Hear, hear.) I have not heard from any speaker in favour of Mr. Brown, or from Mr. Brown himself, anything which could in the slightest degree justify the performance of this operation upon young women without their knowledge, or upon married women without the knowledge of their husbands. I pass by Dr. Routh's observations as idle as the wind. You cannot compare the case of a pregnant woman, or a case of syphilis, or the use of the speculum, with the operation of clitoridectomy. Clitoridectomy leaves her a different woman after the operation from anything she has been before. Dr. Routh had nothing to do with the pregnancy of the woman who confided her secrets to him; it was no crime of his. (Laughter.) He does not participate in the crime by not revealing it to the husband; but if he is an operator in the case of clitoridectomy I maintain he is the faulty person. But on the last occasion I mentioned in this room that I had known cases where clitoridectomy had been performed under terrorism, where patients had been threatened that if they did not submit to this operation they would become insane. Now, I want to hand you a letter from a distinguished practitioner in the country, confirming what I then said. It refers to an unmarried lady of rank. The writer says, "Permit me to say that the result of the operation was found unsuccessful; more than this, it has produced a great aggravation of the previous evil. At the time this operation was performed but little information could be obtained from reliable sources of its alleged value. We had to trust solely to the strong assertions of a person who we had every reason to believe would not advise a proceeding of this kind, unless certain of the good results that would follow. Moreover, the patient was told in my presence that unless she submitted to this mutilation she would soon be in a mad-house." It seems to me that this is as bad a form of terrorism as can be exercised upon a defenceless woman.

(Hear, hear.) Now it appears to me that a main point in Mr. Baker Brown's speech or defence is, "If I have erred I will never do it again. Point out my fault, and it shall never be committed afresh." If we could believe Mr. Brown, I would not stand up upon this occasion. If we could believe Mr. Brown, I think it would be our duty to condone this offence, however great it may be. But what do I find? On January 31 Mr. Brown wrote his letter to the Council, withdrawing his offer of a Committee of Investigation. He withdrew it (note the date) on January 31. On February 4, Mr. Woollaston Pym, the Secretary of the London Surgical Home, wrote this letter to the Medical journals:—"I am directed by the two senior Surgeons, Mr. Baker Brown and Mr. Philip Harper, to state that, solely in deference to the opinion of the Medical press on clitoridectomy, they have determined not to perform the operation in this institution pending the Professional inquiry into its validity as a scientific and justifiable operation. An early insertion of this note in your journal will oblige." This appeared in the *Medical Times and Gazette*, the *Lancet*, and the *British Medical Journal*. Now, on February 21, Mr. Brown performed essentially clitoridectomy in the London Surgical Home, and I maintain that in doing so he was guilty of a breach of faith with every individual member of the Profession who had read that letter of Mr. Pym's. On interrogating the patient subsequently, she told me she did not know what had been done to her; that the nature of the operation had never been explained to her, nor had she been asked if she would consent to the operation. (Sensation.) Now, it seems to me that we cannot give credence to any promises that may fall from Mr. Brown. It appears to me that we must eliminate from practice clitoridectomy, as performed under the ethical conditions of Mr. Brown, or we really must fall down and become worshippers of Priapus. (Applause.) It appears to me the present occasion is one of the most solemn which have ever occurred in the history of the Profession. I know of no other occasion on which medical men have been thinking continuously for months, upon such a question of right or wrong—(hear, hear)—of ethical behaviour as the present. And it appears to me that we must either sink lower than the Profession has ever sunk, now the matter has been widely and thoroughly discussed, or we must really clear ourselves of this subject. If Mr. Brown could perform this operation alone—if he could go his own way—if he could separate himself from us—if we had nothing to do with it—we need not interrupt him. But we have to do with it. He stands not in his own strength; he stands as one of ourselves—(applause)—and we are bound, as it seems to me, to protest against the doctrines which he has urged as to this form of operation.

Mr. BAKER BROWN—I am sure you will allow me one word in reply to what has fallen from the last speakers, in all common fairness. With regard to the case Dr. Smith has related, and the letter he has read, a gentleman of Scarborough called me in to that case. I gave him my opinion honestly. I believed, and still believe, the patient was verging on insanity, produced by perpetual masturbation. He took time to consider, and she also. Two or three days elapsed; a nurse was sent for, and came down from London; and then and there, with his assistance and sanction, the operation was performed. I gave my opinion as an honest man, that she would become insane unless the operation was performed. I believe that masturbation does produce insanity. Am I to be told that I exercised terrorism? I did not see that patient alone. I saw this gentleman who called me in to see her. I gave my opinion, and performed the operation which I thought to be right. But there was no terrorism; and no large fee taken, for I think I had only had ten guineas—certainly not more than twenty (a laugh) for the operation.

Dr. TANNER (of Brighton)—It appears to me we do not meet here for the purpose of discussing the mode of performing operations, neither do we meet as philanthropists, for the purpose of discussing Mr. Brown's moral character, or what were the intentions he had in performing those operations. (A voice: we do.) On the contrary, I assume we meet here as the gentlemen constituting a public body, who have emerged from the difficulties and clouds under which we lay during previous centuries, having achieved a position and satisfied the public that their health in our hands, as men of honour and gentlemen, is safe, and that we shall never presume to go beyond the bounds of what is right, nor at once haphazard, to say, "Because I think so-and-so is right, therefore I will go and do what I think," until we have got something better than one's own poor judgment to go upon. I

take that which has been written and been proved; and if I have a question of doubt in my mind, I put it before a number of men belonging to such a Society as our own, to have their opinion upon it—before I implicate the whole profession by such conduct as Mr. Brown's.

Dr. BARNES—I will merely call to mind the fact that not one of the main charges has been touched upon by Mr. Brown or his friends. He expressly evaded the question I put to him. (Cries of enough, enough; divide, divide; and applause.)

The ballot was then taken, and at its close the scrutineers sent in the following report.—“We, the undersigned scrutineers of the ballot for the removal of Mr. I. Baker Brown from the Obstetrical Society of London, do hereby state that the following is the result:—

For the removal of Mr. Brown . . . . .	194 votes.
Against the removal . . . . .	33 ”
Non-voters . . . . .	5 ”

Total 237

Thus it appears that the motion of the Council for the removal of Mr. Brown from the Obstetrical Society is carried by 36 votes above the required majority of two-thirds.” The names of the scrutineers were appended—Dr. T. H. Tanner and Dr. Edward Parson.

The PRESIDENT—In accordance with the Rules, sec. 2, cap. 4.—“That if on a ballot taking place, two-thirds of the Fellows present shall vote for the removal, the President shall declare the fellow in question removed accordingly”—I therefore declare that Mr. Isaac Baker Brown is removed from the Fellowship of this Society.

Mr. NUNN proposed that a vote of thanks be given to the Council of the Society for their manly, and straightforward, and patriotic conduct of this painful affair.

Mr. CHANCE—I beg to second that. I think the thanks of the entire profession are due to the Council.

The motion was carried *nem. con.*, and the meeting separated.

#### LATEST INTELLIGENCE.

##### THE PRINCESS OF WALES.

THE Princess continues to suffer from the inflammation of the knee-joint, to which we have previously alluded, respecting the progress of which affection our information was quite correct, and that those journals which partially contradicted us were altogether in error. Medical men will readily understand that variations common enough in the progress of such a case will occur. During the week Mr. Prescott Hewett has been called in, and is now in attendance as well as Mr. Paget.

## Medical News.

SCHOOL OF PHYSIC PROFESSORSHIPS.—On the 5th inst., the Royal assent was given to the School of Physic Amendment Act, which we have already given in full in our last number. By this Act Professors Law, Apjohn, Aquilla Smith, and Banks, are respectively re-instated in their Fellowships in the King and Queen's College of Physicians in Ireland.

DUBLIN OBSTETRICAL SOCIETY.—Twenty-ninth Annual Session, 1866-67. Sixth Meeting in the Rotundo, Small Room, down stairs (entrance by Cavendish-row), Saturday, 13th April. Tea at eight, chair to be taken at half-past eight o'clock. Communications—1. A. Walsh, Case of Ovariotomy; 2. S. L. Hardy, Case of Hematemesis in an Infant; 3. J. A. Byrne, Case of Fibrous Tumour of Uterus; 4. H. Gogarty, Case of Early Abortion, Retention of the Placenta and Phlebitis; 5. H. Kennedy, on Fever complicated with Pregnancy; 6. J. H. Sawyer (President), Three Cases of Anomalous Labour; 7. J. Ringland, Case of Retroversion of the Uterus complicated with a Fibrous Tumour.

ODONTOLOGICAL SOCIETY.—At the ordinary monthly meeting of this Society, April 1st, 1867—the President, G. A. Ibbetson, in the chair—Dr. Richardson exhibited and described various modifications of the Ether Spray Apparatus introduced by him; and C. Spence Bate

Esq., F.R.S., read a paper upon the Dentition of the Moles (*talpa europæa*).

The Annual meeting of the Briton Medical and General Life Association was held on the 29th March. The Report stated that 3649 proposals had been received for £1,011,835 12s.; that 2947 policies had been issued, assuring the sum of £304,979 18s. 2d., and yielding in new annual premiums the sum of £26,252 12s. 4d.; the income had increased to £226,151 0s. 1d.; the claims for the year were £141,364 3s. 11d.; the balance of income over expenditure was £65,434 14s. 10d. Mr. Francis Webb occupied the chair; and, in moving the adoption of the report, said the gratification which it had always been the good fortune of the Board to experience on such occasions was somewhat alloyed and mingled with sorrow, through the loss by death of their late chairman, Dr. Barlow. The Directors had respected him as deeply on account of his talents and constant attention to the duties of the Board as for his kindness, courtesy, and gentlemanly qualities. They had also to deplore the loss of three of their trustees, and of Dr. Babbington, one of their consulting physicians. Although they had shared in that high rate of mortality which offices in general had experienced during the past year, there was no reason to look despondingly at the affairs of the Company. If the losses had been heavy during the past year, it must be remembered that the Association had carried over more than 42 per cent. of the receipts the preceding year. The doctrine of averages would readjust any little inequality of the kind. The progress of the institution appeared to be most satisfactory. Notwithstanding the fearful panic and consequent depression of last year they had received proposals for £1,000,000 and upwards, and had issued 2947 policies for £304,979 18s. 2d., producing £26,252 12s. 4d. in new premiums, being an increase of more than £1000 over the new premiums of the preceding year. The average of the policies issued during the year was £320, whereas that of the preceding year was £260, thus showing they were not only increasing in quantity but in the quality of their business. Their income had increased to about £226,000, and their investments were all of a safe and highly satisfactory character. One other circumstance which appeared hopeful for the future was the increased assistance and the constant help they obtained from the medical profession. Each week showed how heartily and cordially the medical profession throughout the whole of England were helping the Association, and how entirely correct were those who represented them here in London in the New Equitable in assuring the Directors that when the office was thoroughly understood, such would be the result. After referring to the indisputable whole world policy now granted by the Association, and to the brightness of the future prospects of the Company, he concluded by moving the adoption of the report. Dr. Tyler Smith seconded the adoption of the report, which was carried *nem. con.* The retiring Directors and other officers were re-elected; a dividend of 8 per cent. was declared; and after the usual votes of thanks had been passed to the consulting physicians, surgeons, consulting actuary, district managers, and agents, to John Messent, Esq., the actuary and secretary, and to the chairman, the meeting separated.

#### NOTICES TO CORRESPONDENTS.

*Inquisitor*.—Certainly a Licentiate of the College may sign himself physician and surgeon if he thinks fit. The midwifery licence qualifies fully.

*A Subscriber and Well-wisher* is thanked for his suggestions. We are alive to the orthographical inelengancies of the contributions referred to, but we do not consider ourselves called upon or even entitled to correct them. The task would be endless, and would involve us in responsibilities which should properly attach to the contributor. We have to exercise a certain amount of supervision to see that communications are intelligible and of scientific interest, but we can go no further.

☞ Owing to a press of matter several important communications are unavoidably postponed until our next issue.

# LIQUOR CARBONIS DETERGENS,

OR

CONCENTRATED ALCOHOLIC SOLUTION OF THE ACTIVE PRINCIPLES OF COAL TAR.

To prepare the Emulsion of Coal Tar, which is applicable to all domestic and therapeutic purposes,

Take Liquor Carbon. Detergens ... .. 1 part.  
Water ... .. 4 parts. Mix.

The following well-authenticated cases will sufficiently show the value of the results effected:—

**Gangrenous Sore.**—Deodorisation at will with the compresses impregnated with the Emulsion at a strength of one-fifth; *rapid cure.*  
**A Wound consequent upon two large Carbuncles; foul odour.**—The same application was followed by immediate deodorisation; sleep restored after the first dressing; wound cleansed; speedy cicatrisation.  
**Ulcers of Leg, probably of Syphilitic origin.**—Rapid improvement in the nature of the puriform secretion, with instantaneous relief; healing promoted.  
**Voluminous Anthroz.**—The Coal Tar Emulsion at one-tenth changed the aspect of the wound, relieved the patient, and removed the slight odour emitted; the cure was more prompt than if ordinary dressings had been resorted to.  
**Impetiginous Eczema of the Ears, with fetid secretion.**—Instantaneous deodorisation, absence of pain, very rapid decrease in the abundance of the suppuration, prompt detachment of the crusts; cure effected in ten days.  
**Interrigo of the Ears, with ulceration and copious puriform discharge.**—Emulsion diluted to one-twentieth; sudden deodorization; cure effected in ten days.  
**Oeana emitting a very offensive smell.**—The patient discharged from a public establishment on account of the disease. Application of the

remedy with a piece of lint, and sponge attached to a whalebone rod; prompt disappearance of fetidity, diminution of the suppuration and swelling; modification of the nature of the secretion; recovery.  
**Ulcerated Chilblains.**—Emulsion diluted to one-fifth; rapid recovery, despite the persistency of cold weather.  
**Pedicularis capitis et pubis.**—Lotions with the alcoholic solution; rapid destruction of the parasites.  
**Ulceration of the ankle of three weeks' duration.**—Recovery after a single application of the remedy.  
**Adhesion and Retention of the Placenta after Parturition; marked putrid odour.**—Injection into the uterine cavity of the Emulsion at one-fifth; deodorisation after one injection, which occasioned a very transient but sharp sensation of heat.  
**Chronic Inflammation of the Gums, with slight hemorrhage.**—Application of the remedial agent, diluted to one-twenty-fifth, with a tooth-brush; rapid cure.  
**Chronic Gleet four months' standing (male).**—Injection in the proportion of 2 drachms to 8 oz. of water, used three times daily; after using the lotion the discharge increased, but altered in character; continued a few days longer (without any medicine); discharge completely stopped on the fourteenth day.

The Emulsion has been used with much benefit in cases of "constitutional ecthyma," giving rise to fetid emanations.

Sold in Bottles, containing One Imperial Pint, at 4s. (Bottle included); and for the Use of Public Institutions Manufactories, Etc., in One Gallon Stone Jars, at 24s. each.

**Liq. CARBONIS DETERGENS.**  
 —We are very sceptical of the value of new remedies, and it was in a spirit of scepticism that we tried the liq. carbonis detergens. It is represented to be a concentrated alcoholic solution of the constituents of coal tar, and to contain all the active ingredients of the tar, to wit, benzine, naphthaline, and phenic acid. The addition of water, with agitation, makes a durable emulsion, in which the tar remains in a state of fine suspension, almost equivalent to solution. Our therapeutical experience of the preparation is very satisfactory indeed. In our hands it has been a most effective agent in the case of various skin diseases, especially of the chronic eczematous class; and one case of psoriasis which had resisted all other kinds of treatment speedily got well under the application of the liquor carbonis detergens. We esteem it a very valuable addition to our list of skin remedies, and worthy of a very extended trial by the profession. In the above classes of disease, and in various others, such as fetid ulcers, &c., the preparation is put into the form of soap. Messrs. W. V. Wright and Co., of Old Fish-street, London, are the manufacturers.—*The Lancet*, December 22, 1866.

## PURE COAL TAR SOAP.

REGISTERED AS

TRADE MARK.

**LIQUOR ET SAPO CARBONIS DETERGENS.**—These form a very valuable addition to our resources. The liquor holds in alcoholic solution the active principles of coal-tar, and is a most ready, cheap, and effective agent. It is valuable for all the medical and surgical purposes to which a deodorising or antiseptic wash can be applied; and, whenever it is desirable to correct foetor, to arrest putrefactive action, and to cleanse a foul surface, the liquor, mixed readily with water, will be found most valuable. The soap contains a large proportion of this material, incorporated by hydraulic pressure. It answers its purpose admirably, and is the only true antiseptic soap with which we are acquainted. For medical men, especially those in attendance on lying-in women, those who frequent the post-mortem or dissecting-room, or those who are attending fever cases or handling wounds, its use will be of the greatest advantage. There are many forms of skin disease in which it would be useful, especially the chronic and parasitic forms. It is a very hard and economical soap for general use; it does not soften and waste in water as many soaps do; and it is pleasantly scented. Both the liquor and the soap are articles of great utility.—*British Medical Journal*, January 26, 1867.

It is a most economical Soap, and from the peculiarity of manufacture differs from all others. For daily use it will be found most refreshing, and, whilst it imparts a softness and cleanness to the skin, it is calculated to ward off *Infectious Diseases*. We are most anxious to secure the recommendation of our medical friends, and hope they will give it a trial.

Lectures.

LUMLEIAN LECTURES

DELIVERED AT THE

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

By J. RUSSELL REYNOLDS, M.D., F.R.C.P.,

HOLME PROFESSOR OF CLINICAL MEDICINE IN UNIVERSITY COLLEGE,  
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, AND TO THE NATIONAL  
HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

ON SOME OF THE RELATIONS BETWEEN MEDICAL AND LEGAL  
PRACTICE.

LECTURE III.

It has been already shown that medical testimony may fail of its legitimate effect, sometimes because it is not scientific, and sometimes because it is. The purpose of the present lecture is to prove that in the established mode of taking scientific evidence, and in the pitting—as it were—of one expert against another, scientific testimony virtually destroys itself. The theory upon which the production of expert testimony rests is this, that it should be such as to guide the jury. It is presumed that the jurymen does not know certain things, and that with regard to them he needs direction from a scientific person. This he may obtain, or might obtain, if the evidence of experts were given as it was intended that it should be; but as a trial is now conducted, the jury is not guided by the scientific witness, but is asked to decide between a number of contending witnesses, each, presumed, more learned than itself. In order to do this satisfactorily, each jurymen ought to be wiser and more learned than each and all of the scientific witnesses. If he be so, it is a great waste of time, words, and money to produce scientific evidence; if he be not, it is absurd to ask him to decide such a disputed question between such disputants.

The points to be decided, for example, in opposed cases of claim for compensation on account of injury are those of diagnosis and prognosis, and a jury is asked to determine these points in very obscure cases, where and when the most learned doctors fail to see eye to eye. The injustice of such a proceeding is often very great; it is felt by all concerned in the inquiry; by plaintiff, defendant, scientific witness, counsel, judge, and jury.

The injured man is not fairly treated, or represented; for the accounts that are given of his state are those of many medical examiners, who have seen him at different times, under different circumstances, in divers places, and with opposite intentions. Each examiner on each "side" takes his own impressions, and conveys them to the court; and there is no free interchange of scientific thought between the contending witnesses. There is an undue reserve in the matter of consultation, and often what is termed a consultation does not deserve the name.

The expert is asked questions which he cannot answer positively; a line of defence is often set up so wide of the mark that it had not been previously considered; and the expression of honest scientific doubt is often made the means of doing great injustice.

The counsel, by being informed on one side only, often make confusion worse confounded; for they are dealing with matters that they do not fully comprehend, and often fail entirely in their attempts to perceive the points of difference between the scientific witnesses.

The judge is often entangled in a web of words from which even he cannot manage to extricate himself; and the onus of decision lies upon the unfortunate jury.

The jury is asked to make a diagnosis, and furnish a prognosis; and twelve unscientific gentlemen are requested to agree when half-a-dozen scientific gentlemen cannot do so, the points upon which they are to agree being precisely those with regard to which the doctors differ in opinion; the materials for their decision, moreover, being the statements that these doctors make. The jurymen

has to weigh not only facts but men, and to decide which witness is the most entitled to his credence. He must, under these difficult circumstances, make a diagnosis for himself; because he cannot rely upon either the age, experience, reputation, or skill of the opposing witnesses, for all these may be so evenly balanced, that they neutralise each other. The production of expert testimony is therefore so elaborate that it virtually destroys itself.

In order to meet the evils that have been enumerated, the following suggestions are made:—1st, That in all scientific evidence, there be a clear line of distinction between facts and opinions. 2ndly, That there be a clear statement on both sides of *all* relevant matter, and that due credit be given to opinions which differ from those of the particular individuals giving evidence. 3rdly, That the symptoms as described or felt by the patient be clearly distinguished from those observed by the physician; with regard to one set of symptoms, there is the testimony only of the plaintiff, with regard to the other there is the evidence of the expert. 4thly, That there should be constructed some fixed schemes or schedules for the observation of cases, analogous to those, for example, which are employed in life insurance offices. 5thly, That there should be some general professional agreement as to the use and meaning of words of constant occurrence in the common cases for medico-legal inquiry. 6thly, That the Profession abstain as far as possible from the attempt at prognosis, with the view of obtaining a more equitable mode of dealing with cases in which the future of the patient is the real point upon which the claim depends; such, for example, as the payment of an annuity, or the insurance of a life. 7thly, That commissions should be appointed to report upon the progress of science, and thus demonstrate the necessity for the removal of old and artificial lines of distinction. 8thly, That the question of the appointment of medical assessors to the Courts of Law, should be considered by the Profession, and its conclusion on that matter authoritatively stated. 9thly, That there should be the fullest and freest interchange of opinion between the witnesses on the two sides of a disputed case; it being believed, that by such a method of procedure nothing would be lost except what it would be well to lose, and that much, now quite unattainable, would be gained by our Profession and the public.

THE CROONIAN LECTURES

DELIVERED AT THE

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

By Dr. ANDREW CLARK.

ABSTRACT OF LECTURE III.

The first part of Dr. Clark's third lecture was occupied by an account of the various experiments made upon animals for the artificial induction of phthisis, and by a critical review of their results. The modes of experiment performed by himself were four. The first plan consisted in keeping animals in conditions unfavourable to health; the second, in causing them to inhale irritating matters with the air; the third, in injecting various matters into the veins; and the fourth, in inoculating with grey tubercle, as first successfully practised by M. Villemin. The result of the first plan was the development in the lungs of yellow lumps which rapidly coalesced and converted the lung into a cheesy-like mass. These lumps were in the beginning composed of epithelium-like cells in various stages of endogenous development or molecular decay, and closely resembled lobular masses of scrofulous pneumonia. They were one of that large variety of lung deposits to which the term TUBERCLE was so vaguely applied, and whose claims to the title *tubercular* would be discussed further on. The second plan, less satisfactorily executed than either of the others, yielded less uniform and definite results. The most common effect was a sort of fibrous disease of lung with cheesy

deposit, resembling in character, though never equalling in degree, the pathological changes induced in the lungs of masons, miners, grinders, and others by the inhalation of irritating particles. The injection of cuttle-fish powder or of sand into the veins was followed by the appearance in both lungs of spherical masses of a yellowish or greyish colour, varying in bulk from the size of a mustard seed to that of a pea. These masses were composed chiefly of cells like the white cells of the blood, having some portions of the injected matter in their midst. When cuttle-fish powder was used, it was readily disintegrated and absorbed, but previous to its final disappearance the crystalline forms contained in it were often found to have made their way from the blood-vessels through the lung to the pleura, upon whose surface they could be felt or seen. *Secondary deposits were sometimes found in the liver and kidney.* When sand was used, the lung deposits produced by it were less frequently absorbed; and in the lungs of dogs whose veins had been injected nine months before, yellowish-grey nodules were found, distantly resembling the grey granulation of man, but quite distinguishable from it by its physical and microscopic characters. In fact, these lumps were nothing more than groups of vesicles, affected with one of the two structural varieties of pneumonia already described. But by far the most interesting and important experiments were those of inoculation, first successfully practised by M. Villemin, and repeated immediately afterwards by Dr. Andrew Clark. When pieces of fresh grey tubercle were introduced into a subcutaneous wound in the neck of the rabbit, a hard swelling, often going on to suppuration, formed at the spot in three days, whilst, in the course of a fortnight or three weeks, grey granulations appeared in the lungs, and afterwards in other organs of the body. Similar results ensued in other rabbits when the inoculating material was taken from the swelling in the neck of a rabbit previously inoculated with grey tubercle from man. The tubercles thus produced in the lungs of rabbits had nearly all the naked-eye characters of the true grey granulation. They projected from the cut surface of the lung; were semi-transparent, dense, tough; and appeared to exist in all parts of the lung indiscriminately. They were, therefore, quite distinct from the masses indifferently called yellow tubercle, which was a common stage in the history of the most various products from grey granulations to pus; and they were quite distinct also from the nodules of scrofulous pneumonia already described as common to the rabbit when placed in conditions with respect to food and air, unfavourable to health.

So far, then, as concerned the production of grey tubercles in the lungs of rabbits by the insertion of pieces of grey tubercle into subcutaneous wounds in their necks, Dr. Clark could testify, from repeated trials, that the experiments of M. Villemin were conclusive. But when it was inferred from these experiments that the grey granulation thus induced in rabbits was identical with that occurring in man, and that the grey granulation was the specific local expression of a specific virus capable, like that of syphilis, of being indefinitely propagated by inoculation. Dr. Clark held that the conclusions were not justified by the evidence adduced in their favour, and must be received with extreme reserve. The grey granulation of the rabbit differed in some important points from that of man. The former occurred as commonly at the base as at the apex of the lung; it was seldom, if ever, seated in the areolar tissue surrounding the bronchi and blood-vessels, or in the substance of the pleura; it was cellular instead of nuclear or corpuscular in structure; it was often absorbed; and as yet it had not been found to give rise to those secondary changes produced by the grey granulation in the lung of man. And, even admitting that the grey tubercle produced in the lung of the rabbit by inoculation was structurally identical with that of man, or homologous with it, it did not follow that its presence was due to the action of a specific virus communicable by inoculation, in the strict sense of that term. For, first, the experiment consisted in the introduction into

a subcutaneous wound of pieces of grey tubercle, which there decomposed and gave rise to great local irritation; and this, therefore, was no mere affair of ordinary inoculation. And, in the next place, Dr. Clark had twice succeeded in producing grey granulations by using for inoculation non-tubercular instead of tubercular matters. Moreover, if tubercle were really inoculable in the sense that syphilis was, the disease would be more communicable from husband to wife, more extensively hereditary, and much more common than happily it is among men engaged in studying the morbid anatomy of phthisis.

Years ago a true inoculation was tried for the induction of tubercle by Klencke, among others. But it was plain, from such accounts of the results as had come down to us, that the lesions met with in the lung were not true grey granulations, but the so-called yellow tubercles or islets of scrofulous pneumonia, which was the peculiar disease of the lung of the rabbit, and had, in all probability, occurred in the cases referred to independently of the act of inoculation.

Dr. Clark considered it of the utmost importance to the right interpretation of the results of these experiments to keep before the mind the absolute distinction which exists between the grey granulation and the so-called yellow tubercle. Without the light of this distinction, there was no way out of the obscurity in which the subject was involved.

## NOTES OF A LECTURE ON DISEASE OF THE JOINTS.

By HOLMES COOTE, F.R.C.S.,

SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

IN speaking of inflammatory diseases of the articulations, I wish it to be distinctly understood that there are but two structures which admit of primary inflammation—namely, the synovial membrane and the articular extremity of the head of the bone. Of the former we have a familiar example in the case of hydroys articuli; of the latter, in the case of ulceration of articular cartilage. But this latter term is falling into disuse, for the ulceration of the cartilage depends upon a morbid condition of the cancellous tissue of the bone, and is consequently a secondary affection. Hence this group of affections is divided into "synovitis" and "disease of the joint;" the former for the most part transitory and easily managed, the latter more obstinate and attended with severe pain. It may be readily surmised how tardy is convalescence in the second instance, for the part of the bone intended to support the weight of the body is no longer in a condition to perform that function; it is painful and tender, and between its free surface and the cartilage now loosened there is a layer of exquisitely sensitive granulations. Hence the limb almost insensibly assumes that position in which there is the least amount of pressure between the opposed surfaces. In the case of the knee the joint is always flexed. In the further progress of such a case we find the ligaments softened by secondary inflammation, and they become elongated, so as to admit of displacement of the bones. During the acute stage any attempt at extension adds greatly to the patient's sufferings, and cannot, indeed, be borne.

The disease may be said to go on until the bone has recovered its healthy state, but it unfortunately often happens that before that time has arrived the articular cartilage has been in great part, if not wholly, destroyed; and then we meet with those cases, so common in the Hospital, where the patient recovers with a bent and deformed limb.

In former times a bent limb was often amputated as a useless and inconvenient appendage, but we have now two methods of correcting the deformity; one by forcible extension, the patient being rendered insensible by the use of chloroform; the second, a painless proceeding by means of gradual extension, and although cases occur in which one proceeding may be demanded in preference to the other, yet I prefer, as a rule, the gradual extension.

You cannot form any estimate of the amount of laceration of internal parts when force is used, and structures may be damaged which you wish to preserve.

Those cases which do not yield to forcible extension are cases of bony ankylosis—a somewhat rare occurrence—and you may generally ascertain whether the obstacle be bony or not by pulling at the limb. In the case of osseous ankylosis, the parts being immovably fixed, there is no muscular contractions in the muscular structures around. In the case of fibrous ankylosis, the more common form, there is some amount of yielding, and the surrounding tendons are felt to spring from their sheaths on the application of extending force.

In the event of the tendons opposing any serious amount of resistance they may be readily divided subcutaneously; but this is a measure rarely necessary in the young.

You are aware that I am no advocate for the resection of diseased joints. The successful results which are brought about by soothing remedies, rest, and by patience, have been amply illustrated by cases which you may see in the hospital.

We cannot always arrest morbid action; but we may keep the limb in that position which is easiest to the patient, and thus favour recovery. The restoration of the limb to its proper form is a matter of later consideration.

## Original Communications.

### ON DREAMING, CONSIDERED ESPECIALLY IN RELATION TO INSANITY.

By THOMAS MORE MADDEN, M.R.I.A.,

LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND, MEMBER OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, AUTHOR OF AN ESSAY "ON INSANITY AND THE CRIMINAL RESPONSIBILITY OF THE INSANE," "ON CHANGE OF CLIMATE, A GUIDE FOR TRAVELLERS IN PURSUIT OF HEALTH," &c., &c., &c.

(Continued from page 333.)

INDEED, it must, I think, appear most probable that as long as vitality remains there can never be a complete cessation of thought; and the mind, during sleep, as well as during the waking state, continues to operate, even though in the former condition the consciousness of its operations be suspended, and though the mind may then act faintly or imperfectly; or, perhaps, in a totally different way from that in which it acts during the waking state. Every one who has had occasion to sit up with invalids, and to watch them during sleep, knows that dreamers are seen to toss about in bed, to express various emotions in their countenance, are heard to moan and talk in their sleep, and are known to enact their dreams, as in the case of somnambulists, all without any recollection whatever of having dreamt, and such persons, when they are aroused from a dream in which they have given manifest signs of their state, will often insist that their sleep has been perfectly calm and undisturbed.

It is evident that the condition of the mind of a dreamer, must be very different from the mental state of the same person when awake. In the latter case the current of thought (except when the individual is absorbed in deep reverie, which is a state very analogous to dreaming) is influenced and modified by the constant succession and change of external impressions transmitted by the senses. But in sound sleep all impressions from the external world are either entirely shut out, and the mind is no longer in any degree under the dominion of their suggestions; or else, as is perhaps more frequently the case, these impressions are so faintly or imperfectly conveyed as to produce sensations and results altogether different from those they would have occasioned in the waking mind.

The laws of association of ideas, which have been applied by metaphysical writers to explain the nature of dreaming, cannot be accepted by physiological inquirers as affording any satisfactory insight into the character of

this remarkable condition. For, even in the waking state, as must be obvious to every one, ideas frequently arise perfectly unconnected with any preceding train of thought, and not suggested by any cognizable external cause. It seems, I think, indubitable that the same must occur in dreams, in which state impressions or ideas, probably long existing in the mind, although obscured by more recent impressions may, when, as is the case during sleep, the thoughts with which we are occupied are suspended, be renewed by the uncontrolled imagination acting on the memory, and bringing up before our mental sight images as distinct, for the time, as when they were originally imprinted on the mind. Such a renewal of former mental impressions, variously combined, constitutes a dream.

The theory advocated by Spurzheim, that dreams are occasioned by certain organs of the cerebrum remaining awake while all the other portions of the brain are in the sleeping condition, affords the most plausible explanation of the remote cause of dreaming. This hypothesis may be easily amplified if we admit the conjecture that the exhaustion of nervous power which occasions, and is repaired by sleep, is seldom, if ever, complete; and that the unexpended nervous energy acting on the organ of the mind gives rise to dreams. The character of the dream in each case being, perhaps, influenced by some physical impression made on the waking part of the brain, and transmitted to it by the nerves from distant parts of the body.

Impressions, however, may also originate from within the brain itself, as well as be transmitted to it from without. That such may be the origin of some dreams is more than probable for such, as far as we know, is the nature of those sensations, for example, which patients who have undergone a capital operation, occasionally refer to limbs which no longer exist. Of a character, too, are those hallucinations of the organs of special sense that occur in the course of many febrile and nervous complaints, and also in some chronic maladies. These false perceptions of taste, sight, and hearing, occasionally commence in dreams, although they may be continued into, and influence the waking senses. Thus, for instance, a gentleman under my care suffering from dyspepsia, dreamt one night that he was compelled to eat *mal gre lui*, a quantity of molasses, and on awaking perceived an intensely sweet taste on his palate. This lasted for eight or ten days, and for that time altered and perverted the flavour of everything the patient ate or drank. A somewhat similar case is recorded by Dr. Millingen in his "Curiosities of Medical Experience" (p. 311), in which the sense of vision was effected by an hallucination commencing in a dream. Closely related to this part of the inquiry into the nature of dreams, a subject of considerable interest in connection with the medical jurisprudence of insanity presents itself. In his well-known work on "Obscure Diseases of the Brain," Dr. Forbes Winslow narrates several instances in which dreaming appears either directly or indirectly to have led to the commission of serious crimes of various kinds. "A person," says this eminent psychological physician, "apparently well, has gone to bed without manifesting the slightest tendency to self destruction, and on being suddenly aroused from a frightful dream has destroyed himself." (1) The same author also refers to some cases in which murder was apparently committed under the influence of dreams. And, in a communication I had the honour to read before this Society on the 21st. of March, 1866, I made some observations on a very remarkable case of a somewhat similar character to those described by Dr. Winslow. (2)

### III. VOLITION NOT NECESSARILY SUSPENDED DURING SLEEP.

We find it asserted by some physiologists that the essential character of sleep is the suspension of volition. But this proposition is far from being generally true,

(1) Dr. Forbes Winslow "On Obscure Diseases of the Brain, and Disorders of the Mind," p. 592. London, 1861.

(2) Dr. Thomas More Madden "On Insanity, and the Criminal Responsibility of the Insane," pp. 15, 16. Dublin, 1866.

unless, indeed, we admit that dreaming and sleeping are two separate states of existence. For although the power of controlling and changing the subject of our thoughts is generally suspended in dreams, yet there are many and striking exceptions to this law recorded, especially by Abercrombie and Reid, in which the dreamer had the power of stopping a dream at a particular point. And, even without referring at all to the question of somnambulism, another objection to the theory that volition is of necessity lost during sleep is presented by the well-known phenomena of incubus, or night-mare, in which volition, although without the power of executing the act willed, appears to be exerted. Dryden has so admirably rendered Virgil's description of this state that I cannot refrain from quoting it:—

"And as when heavy sleep has closed the sight  
The sickly fancy labours in the night,  
We seem to run; and destitute of force,  
Our sinking limbs forsake us in the course:  
In vain we heave for breath, in vain we cry;  
The nerves, unbraced, their usual strength deny;  
And on the tongue the faltering accents die."  
(ÆNEID B. xii., L. 908.)

In such dreams it is evident that it is not volition, but the power of co-ordinating the movements which are willed that is suspended by sleep. The cerebellum in dreams being probably quiescent while the cerebrum is active, and therefore no voluntary action can respond to the exercise of the will.

#### IV. CHARACTER OF THE VISUAL IMPRESSIONS OF DREAMS.

It is a generally received opinion that the impressions of visible objects seen in dreams are effected in the retina, from which they were originally, at some previous time, transmitted to the brain, and thence are returned during the dream by the optic nerve, and produce their impression on its ocular expansion. If this theory were correct, however, it would be impossible to explain the phenomena of dreams in persons born blind, or in whom the retina has been destroyed by disease, and who, nevertheless, continue to dream of visual objects. It therefore seems, I think, more probable that the visible objects of dreams are independent of the ordinary channels of vision, and are produced directly within the sensorium.

#### V. SLEEP-TALKING

Into the question of somnambulism I shall not attempt to enter on the present occasion, as the subject is too extensive. But I should gladly, if I should ever have the time and opportunity, for so doing, treat of it as a distinct and most interesting subject of investigation. I may remark, however, that in the state of sleep-talking, which is a form of somnambulism, it appears as though the mind had regained its command over the voluntary muscles which are connected with the vocal organs, and that these respond to the will, and perform their accustomed functions in proportion to the vividness of the dream as well as the strength of volition and state of health of the dreamer, being most energetic when the sleeper's health is most delicate. In those rare cases in which the dreamer responds to questions, and to a certain extent is capable of entering into conversation while still asleep, the person's condition is evidently that of partial or imperfect sleep. For not only is the external impression transmitted through the *portio mollis* of the seventh cerebral nerve in the ordinary manner, but, moreover, it produces its ordinary action on the portion of the brain connected with the sense of hearing and volition is excited and transmitted to the voluntary muscles of the parts by which the response is made, thus clearly showing that these organs are not under the dominion of sleep.

#### VI. TRANSITORY CHARACTER OF THE MENTAL IMPRESSIONS MADE BY DREAMS.

The evanescent nature of the impressions made on the mind by dreams is a matter of familiar observation. It is nearly always exceedingly difficult and generally, indeed, impossible to recall to memory an hour or two after we

awake the very subject of even the most vivid dream; and when we do succeed in recalling the subject our recollections are generally vague, indefinite and obscure. This very curious fact, has, I believe, never been in any way accounted for. The only condition that appears to present an analogy in this respect to dreaming, is the state produced by the action of certain stimulating narcotics, such as alcohol, opium, and chloroform, under the influence of which acts are performed and things are suffered of which no trace at all (or at any rate one as indistinct as the recollection of a dream) is left on the memory when the effect of the drug has passed off.

#### VII. "SLEEP-INDUCING HALLUCINATIONS."

Under the above name, Mons. Maury and other recent French writers on this subject describe a form of spurious dreaming which presents a very close analogy to insanity, and that which M. Maury states is very common even in persons whose mental as well as bodily health are equally good. These "sleep inducing hallucinations," as they are called, consist of spectra, which appear before the mind just at the moment of sleep, and which, according to M. Maury, are reproduced in the ensuing dream. (1) My own observations, however, lead me to think that this phenomena is not so commonly met with as the writer I have just referred to supposes. In fact, of the very large number of persons I have questioned on this subject very few indeed were conscious of these "pre-somniferous hallucinations." I know one person to whom they sometimes occur, but as far as he is conscious of are never reproduced in the succeeding dream. Occasionally these hallucinations are so vivid that the delusion continues even after the eyes are open. Some months ago after having passed a restless night, this individual was dozing off towards morning, when in the transition state between sleeping and waking, two spectra, whose faces he felt quite familiar with though they were of colossal size and were clad in the costume of last century, appeared standing one at each side of the foot of the bed, over which they leaned upon their halberds. To assure himself that he was not dreaming, he opened his eyes and sat up in the bed, but the hallucination still continued for some time as distinctly as before, and then suddenly disappeared. This case presents a good example of the close resemblance between the phenomena of the state just described and insanity. Here was an impression produced by a hallucination on one of the senses, which was as vivid, for the time, as if it had been produced by an objective cause, and had this hallucination extended to the other senses, and if the person had not been able to reason rightly that this impression was unreal, the illusion would have become a delusion, and the individual would have been insane. So nearly do the confines of sanity and insanity approach in dreams. The individual to whom the foregoing hallucination occurred explained it by "the Laws of Association," as laid down by the Rev. Dr. Wills. For, the day after the dream I have spoken of, this gentleman visited the exhibition of the Royal Dublin Society, and there, to his surprise, recognised the figures he had seen in his dream in the nudes in Mr. — excellent painting of "Goldsmith Mourners," which, he says, must impressed itself on his mind at a preceding visit, although he could not recollect having seen it before.

The most noticeable points of resemblance between dreaming and insanity are the loss of all power of discriminating between the possible and the impossible, the absence of surprise at the most astonishing scenes and events, and the ready credulity with which absurd contradictions and impossibilities are quietly accepted by the mind as facts. Another peculiarity of the mind in dreaming, is want of consecutiveness, and connexion between the various dreams which succeed each other, the mind passing with ease from one subject to another in no way connected to it in the same manner as it also does in insanity.

## VIII. OCCASIONAL MANIFESTATION OF MENTAL POWER DURING DREAMS.

One of the most remarkable phenomena in connection with dreaming is the occasional manifestation of intellectual activity by persons in this condition. Though this fact is doubted by some psychologists, and amongst others by Rosenkrantz and Baron von Feuchtersleben, who asserts that "intellectual problems are not solved in sleep, because intense thought is without images, whereas dreaming is a creation of images."<sup>(1)</sup> This assertion, however, is directly opposed to many well-known cases, in which the full powers of the mind have been exercised by persons apparently in a sleeping condition.

Sir Thomas Brown goes so far as to believe that "Sleep is the waking of the soul; the ligation of sense, but the liberty of reason." Condillac states that while engaged in his "Cours de Etude," he frequently developed and finished in his dreams a subject which had engaged his attention when he retired to rest. Condorcet had presented to him in sleep the solution of a difficult calculation that had puzzled him all the preceding day.

"Nous avons quelquefois," says Cabanis, "en songes des idées que nous n'avons jamais eues. Nous croyons converser, par exemple, avec un homme qui nous dit des choses que nous ne savons pas. J'ai connu un homme très-sage et très-éclairé (Franklin) qui croyait avoir été plusieurs fois instruit en songe de l'issue des affaires qui l'occupaient dans le moment." Cabanis accounts for this by supposing that the mind continues to occupy itself in such cases with its waking thoughts, and continues these with the fictitious creations of the dreaming imagination.<sup>(2)</sup> The same thing is said to have occurred to Brindley, the engineer, when constructing the Bridgewater canal. Dr. Gregory, too, stated that he found his dreams often occupied by thoughts and arguments "so just in point of reasoning and so good in point of language" that he made use of them in his lectures.

Goethe says in his *Memoirs*: "The objects which had occupied my attention during the day often reappeared at night in connected dreams. On awakening, a new composition, or a portion of one I had already commenced, presented itself to my mind. In the morning I was accustomed to record my ideas on paper."<sup>(3)</sup> In Lord Jeffrey's life it is stated that this judge of unenviable notoriety entertained a somewhat similar opinion. "He (Lord Jeffrey) had a fancy that though he went to bed with his head stuffed with the names, dates, and other details of various causes, they were all in order in the morning, which he accounted for by saying that during sleep they all crystallized round their proper centres."<sup>(4)</sup>

The well-known history of the composition of Coleridge's poem of "Kubla Khan" during sleep may also be here cited as a further illustration of my statement. We read that in the summer of 1797 Mr. Coleridge, being then *in ill health*, was rusticated in a quiet farm-house in the country. On one occasion, having previously taken an anodyne, he fell asleep in his chair, while reading in "Purchas Pilgrimages" a passage referring to the Khan Kubla. He slept on for three hours, and during this time, as he subsequently asserted, he had the most perfect confidence that he composed from two to three hundred lines of poetry whilst still asleep, and did not experience the least consciousness of effort in so doing. When he awoke he had a perfect recollection of the whole poem, and instantly wrote down the fragment which exists of "Kubla Khan." But whilst thus engaged he was called out of the room for about an hour, and on his return he found that he had lost all distinct recollection of the poem, although he still retained a dim consciousness of its general purport, and even remembered a few scattered lines.<sup>(5)</sup> The late Sir B. Brodie (in his "Psychological Inquiries") relates a somewhat

analogous case, in which a friend of his, whose mind had been deeply occupied with some abstruse scientific point, about which he failed to satisfy himself, imagined that the matter had been cleared up suddenly in a dream. It would be easy to add to these cases, but enough has been said to prove that the exercise of mental power is not incompatible with the sleeping state.

It must be admitted, however, that such cases as the foregoing are comparatively rare exceptions, and that the faculties most commonly exercised in dreams, are the memory and the imagination, unbridled by the judgment.

The sense of the ludicrous is occasionally highly developed in dreams. I know a gentleman who seldom indulges in a pun when awake (although when he does attempt them they are generally good), but when asleep he frequently fancies that he has made a capital pun, which amuses him exceedingly at the time, though on recalling—which he can always do in the morning—he finds that it is very far from being as witty as he had supposed.

Sir Thomas Brown thus recorded his own experience on this subject—"I am in no way facetious, nor disposed for the mirth and galliardise of company; yet in one dream I can compose a whole comedy, behold the action, apprehend the jests, and laugh myself awake at the conceits thereof. Were my memory as faithful as my reason is then fruitful, I would never study but in my dreams, and this time also would I choose for my devotions; but our grosser memories have then so little hold of our abstracted understandings, that they forget the story, and can only relate to our awakened souls a confused and broken tale of that that hath passed."

(To be continued.)

## PSEUDO-HELMINTHOLOGY: OBSERVATIONS ON CERTAIN SUBSTANCES LIABLE TO BE MISTAKEN FOR INTESTINAL WORMS.

By Dr. WM. FRAZER, M.R.I.A.

HONORARY MEMBER OF THE MEDICO-CHIRURGICAL SOCIETY OF MONTREAL, ETC.

*Cells of Orange Pulp mistaken for Entozoa and for Hydatids.*—Three examples of this curious mistake have occurred to me. The first was referred for investigation some years ago from the north of Ireland by a physician who wished to ascertain whether the strange substances his patient had passed from his bowels were hydatids, as their appearance had given rise to much uneasiness. When informed of their nature his reply was, "I beg to thank you for your kindness in examining the supposed hydatids, the patient has been using oranges, and you are perfectly correct."

The second case was submitted to me by Dr. Austen. A delicate child had got an active vermifuge under the idea of worms being the cause of her ill health, and undigested cells of orange pulp were discovered in the alvine discharges, these were alleged to be genuine intestinal worms, but doubts having risen about these supposed ascarides, he wished to have them examined. Dr. Austen's own impressions were opposed to their being worms, and his note in reply to my letter was, "You are perfectly correct as to the supposed worms, the child had eaten an orange or two for several days consecutively, the matter is really rather ludicrous."

In the third instance, a young gentleman of delicate appearance was brought me by Dr. Kirwan; he displayed some substances floating in a phial of water, which he had picked out of the evacuations, and believed he saw them *distinctly moving*, they were cell walls of orange pulp, the contents being quite digested. When told what they were, he admitted that he had eaten the fruit. He was suffering from impaired digestion, and complained of irregular action of the bowels.

*Undigested Celery mistaken for Ascarides.*—Some years since a gentleman brought me several long undigested fragments of celery stalk, chiefly consisting of the stringy

vascular tissue, which he fancied were worms, he had seen some ascarides lumbricoides passed by a child, and was convinced he was infested by them. The microscope showed their vegetable nature and rendered their recognition easy. It is not unusual for persons who have feeble digestion to excrete unaltered vegetable substances consisting of indurated vascular tissues or of sclerogen, and even the cellular portion of vegetables may pass off undigested, and it must be admitted in excuse for this patient's error, that the fragments of celery he mistook for entozoa were not unlike semi-digested ascarides.

*Plastic lymph intestinal exudation mistaken for Tape-worm.*—In this distressing case a physician of great promise was attacked with plastic lymph exudation of the intestines; he had suffered from griping abdominal pains and a train of nervous symptoms, when some fragments of lymph matter being expelled, he was supposed to have tape-worm and advised to use drastic purgatives and anthelmintics, these had the immediate effect of aggravating his symptoms, severely injuring him and increasing the number and size of the expelled masses. The specimens that I examined were of pure white colour, seldom exceeding half an inch in length and of irregular shape, consisting of granular substance which passed into fibrillation on the surface that appeared to have been attached to the intestine. The lymph fragments continued to form at intervals for several weeks until he left Ireland for a protracted sea voyage, and soon after his departure he ceased to pass these plastic masses.

*Larvæ of Diptera supposed to be Worms.*—In two instances, of which I have preserved no notes, dead larvæ of some fly were brought to me under the idea of their being intestinal worms, they were stated to have passed from the bowels, which was possible, though their presence might admit of other explanations.

*Elastic-ligamentous Tissue supposed to be Tape-worm.*—Some years ago a woman in the wards of the Hardwicke Hospital, under the charge of Sir D. J. Corrigan, fancied she was attacked with tape-worms, the alleged worms were submitted to me for microscopic examination, they proved to be a quantity of fragments of ligamentum nuchæ which she had eaten weeks previously, they lodged in the cœcum, causing distinct fulness in that region, and required repeated purging for their expulsion. This case was recorded by Sir D. J. Corrigan in one of the early numbers of the *Dublin Hospital Gazette*, and affords a good illustration of the value of microscopic examination in determining the nature of doubtful substances.

### CASE OF DEPRESSED FRACTURE OF MASTOID PORTION OF TEMPORAL BONE:

WOUNDS OF PHARYNX, TRACHEA, THORAX AND ABDOMEN: RECOVERY.

By JOHN P. QUINLAN, Esq., L.R.C.S.I., etc., Borrisoleigh.

I was called out of bed on the night of the 14th of March, to attend a man named Carroll, about 30 years of age, who had been attacked about a mile from Borrisoleigh, on the road leading to Upper Chanto. I found, on arriving at the scene of the outrage, that he had been conveyed to a neighbouring house, having (as was evident on inspection in the morning of the road where he had been lying), lost a considerable quantity of blood. I observed on examination that he had sustained the following injuries.

Two scalp wounds, one on the right parietal bone, about an inch below and behind the anterior fontanelle. This was somewhat "elliptical in shape," running parallel to the saggital suture, and presenting at its inferior edge a partially separated portion of integument in the form of a tongue-like prolongation as if the wound were inflicted with a two bladed instrument. The pericranium was exposed through nearly the entire extent of the wound. The incision was about an inch in length. The other, of somewhat similar extent, began immediately behind the ear, on the same side, crossed the mastoid portion of temporal

bone rather in an oblique direction from below, upwards and backwards. The mastoid portion was broken off nearly in the line of the external wound. It was also depressed.

The face presented several incised wounds, one in particular beginning just at the ala of the nose on right side, and extending directly upwards to within about half an inch of the orbit, its course being parallel to the lateral cartilage, here it would seem that the weapon glanced off the superior maxilla, and caught again in the structures over the supra-orbital ridge after passing the eye-ball. The structures were divided down to the bone for nearly an inch in a direction upwards and outwards. This incision began about the situation of the pulley of superior oblique muscle, and the supra-orbital ridge of the frontal bone was slightly depressed. The other facial wounds were slight. On the right side of the neck I observed a clean incised wound crossing the sterno-mastoid muscle, in a transverse direction, about two inches above its sternal origin, and dividing its superficial fibres. On the left side was another, beginning about an inch from the symphysis menti, and extending along the ramus of the lower jaw, as far as the angle. The left side of the neck presented several incised wounds, completely dissecting up the integuments and subjacent structures, as low as the pomum Adami, exposing it and the submaxillary glands, but without wounding any important vessel, the cervical portion of the facial artery having escaped injury.

The trachea was perforated about its second or third ring, to the left side of the median line, and the separated muscular structures flapped considerably during respiration.

The pharynx also was wounded near its termination in the œsophagus. The fluid which the patient drank trickled freely through one of the wounds on the left side of the neck. There were five or six punctured wounds of the thorax, but, with one exception, none entered the cavity.

On examining the abdomen, I found six punctured wounds. I cannot say whether all entered the cavity, but one at least passed through the parietes, as I found the omentum protruded, to the extent of about an inch and a-half, through an aperture about an inch above and to the right side of umbilicus.

I found some sand from the road where he had been lying entangled in the folds of the protruded portion. This was very carefully cleansed before being returned. The other wounds were treated on ordinary principles. I visited him again next morning. The wound of the trachea seemed healed, at all events there was no longer the flapping of the integuments, which I have noticed as having been observed the previous night.

The pharyngeal wound, however, was still open, as fluids drank by the patient continued to escape. There was considerable dysphagia and pain; he was now quite conscious.

Being obliged to attend the assizes in Nenagh, I recommended that he should be removed to Thurles, where his friends lived; here he was attended by Dr. Russell, with whom I visited the patient on the 23rd (March), and ascertained that the wound of the pharynx closed within three days after the receipt of the injury. The difficulty of swallowing also, which was at first such an urgent symptom, was also now entirely removed.

I learned also from Dr. Russell that he had not suffered from any inflammatory symptoms either of the pleuræ or peritoneum, and required nothing whatever but to have his wounds dressed in the usual way.

I saw him again on the 28th (March). He was then quite convalescent.

**CATTLE PLAGUE.**—The cattle-plague has again appeared in Northamptonshire, on the farm of Mr. Joseph Goodman, of Drayton Grange, Daventry. Sixteen of his beasts were slaughtered on the night of the 27th ult., and the local cattle-plague committee have declared his premises infected with an area of one mile from the boundary thereof. The disease, however, is not rinderpest.

## Hospital Report.

RICHMOND, WHITWORTH, AND HARDWICKE  
HOSPITALS.

Dr. LYONS'S CLINIQUE.

### ERYSIPELAS AS A SEQUELA OF TYPHUS.

SOME remarkable examples of erysipelas occurring in the sequel of typhus fever have been presented in Dr. Lyons's clinique, illustrating the spontaneous origin of this latter morbid state, and its active communicability when once so developed. The occurrence of the erysipelatous tendency has been noted on two distinct occasions in the same ward, separated by an interval of nearly two months. In the first instance a patient recovering from well-marked spotted typhus, and suffering from a bed sore on the buttock which, however, healed kindly, presented without marked premonitory symptoms an erysipelatous blush on the face. The nose, eye-lids, fore-head, and head and face generally, soon participated in the morbid condition, and the patient's state for some days was such as to cause well-grounded alarm. Under the use of tonics (bark and ammonia), with liberal stimulants, the patient ultimately made a good recovery. As a disinfectant carbolic acid was freely sprinkled on the bed-clothes and the floor, and all means were adopted to limit the extension of the disease. When this patient was nearly convalescent it was found that a second typhus case began to exhibit erysipelas of the head and face. This latter case was remarkable for the extreme typhous prostration, and the dark colour of the rash it had presented, having been in fact an instance of the lowest form of putrid typhus, with extreme depression of the circulation and temporary obliteration of the cardiac impulse and first sound. That such a case, when not fully convalescent from the typhus state, should exhibit a pathological condition in many respects so different as erysipelas, is, in Dr. Lyons's opinion, not a little remarkable.

This patient ultimately recovered. In all seven cases were affected with erysipelas in this first epidemic, of which one only died (of erysipelatous pericarditis.) The disease then disappeared from the ward, but in about two months subsequently again presented itself as the sequel of a case of pure maculated typhus. This case ultimately recovered. A second patient likewise went favourably through his primary fever, and the subsequent erysipelas, but a third case much worse, and with protracted diphtheria, partially developed an erysipelatous rash upon the face, which did not extend beyond the nose and adjacent portions of the cheeks. A day or two subsequently, metastasias to the heart took place suddenly; rapid pericardial exudation and serous effusion ensued, and the patient succumbed on the twenty-seventh day from the commencement of his fever (typhus.)

### RENAL DISEASE—UNUSUALLY SMALL KIDNEY.

P. N., æt. 40, by trade a harness-maker, was admitted into the Whitworth Hospital on the 13th of February last under the care of Dr. Lyons.

It was ascertained that the patient had been long given to intemperance; after Christmas he drank for a fortnight, and subsequently was attacked with sore throat, puffiness about the eyelids, and slight swelling of the abdomen. He was a man of pale and anæmic appearance. His urine was found to be highly albuminous and of a clear colour. Dr. Lyons prescribed for him one fluid dram of the solution of Perchloride of Iron, in eight fluid ounces of water, half-ounce every third hour; and also twelve pills, of which two were directed to be taken every alternate night according to the following formula:—*R.* Pil Rhei Co; Pil Colocynth, Co aa. gr. xxx; olei Crotonis gtt. ii. Misc. Further, a blister was applied to the throat; and this (we were informed) gave the patient much relief.

On the 14th of February the urine was of a very pale colour, and its specific gravity from that date to the 24th February was tabulated thus:—

S. G. 14th, February	1008
17th	1010
18th	1008
20th	1008
21st	1007
24th	1008

On the 26th of February he was discharged much relieved; the swelling had quite disappeared from the eyelids and abdomen, but still albumen continued present in the urine

On the 1st of March he was re-admitted, having been again drinking during the three days following his discharge. He was then (1st March) found to have a sore throat, of which he complained most; he was anæmic as before, but had no return of dropsical symptoms. The heart's sounds were normal; the urine, of which he passed large quantities during the day, was albuminous of clear colour, and of S. G. 1008. He expectorated small quantities of blood; and was ordered the same treatment as on his first admission. No symptoms of an urgent nature showed themselves until the 12th of March, when he seemed to have caught cold. He could not get warm, and his nose became red and swollen. On the 14th he complained of pain in his stomach; and this pain shifted from the epigastrium to the right hypochondriac region. He also complained of a general uneasiness. The pain was relieved by a linseed poultice. In the evening a very distinct double frotement was heard all over the præcordial region. Pain was felt on pressing in the left costo xiphoid space. There was not any tenderness over the heart; the pulse was 104, and strong. At this time he had a distressed look about his face; his breathing was still laborious and deep; while he felt very uneasy in bed he had no difficulty in lying on his left side; he was described as being "silly" in his manner, and drank a large quantity of water.

15th. The friction sound is still audible, and it is intensified by pressing a little with the stethoscope; the breathing is laborious and deep; the patient appears to be very uneasy with tossing about in the bed, and expectorates small quantities of blood; the pulse is quick. His face presents the appearance of great distress, and he complains of acute pain over the heart, which, he says, is "broken." Three leeches were applied over the præcordial region, and their application was followed by considerable relief to the patient.

16th. Distress in breathing, restlessness, tossing about in bed, and pain in the præcordial region continue. The friction sound is also still audible; mucous rales are heard all over the chest; pulse 92. Six leeches were applied over the heart, this gave some ease.

17th. At 6 a.m. he experienced great dyspnoea and expectorated frothy mucus. As on yesterday, there is every appearance of distress in his face; and mucous rales were audible over the chest; pulse 92, and total absence of delirium. He was ordered stimulants, and a linseed meal poultice to the leech-bites. Died at 6.50. a.m. more suddenly than was expected.

On making a post-mortem examination, Dr. Lyons found evidences of extreme, general, and acute pericarditis. A considerable amount of lymph had been exuded, and there were also found bands partly connecting the surface of the heart and the parietal pericardium. Traces of inflammation of the larynx were also discovered; the glottis was thickened, and was very red on its posterior inferior surface. One of the kidneys was in a state of advanced fatty renal degeneration. Its cortical portion was diminished, and the pyramidal portion was deeply stratified with fatty matter. The other kidney was extremely small, weighed under an ounce, and if divested of its fatty matter weighed only 359 grains. On making a section through this kidney, Dr. Lyons found it also to be in an advanced state of degeneration. He did not, however, think that its very small size could be accounted for by the progress of the disease in the other kidney; and in fact he could not then satisfactorily account for the difference between the two in this respect. In cirrhosis the diminished kidney was found to be hard, granular, on the surface, and otherwise differed in

appearance from the present case. He inclined to the view that it was simply an instance of a kidney originally ill developed, which, like its fellow, became attacked with disease, and its intertubular tissue became degenerated. He had no doubt, however, that it was smaller after the attack of the disease than it was before it.

In remarking on this case, he noted that the patient had gone on for a long time with scarcely any symptom of disease. For nearly three weeks before admission to hospital he worked at the trade of a harness-maker, having no idea of being in any way ill. Dropsical symptoms were absent; he passed light-coloured water, and suffered from a little headache, and these symptoms could be otherwise accounted for than by the hypothesis of his case being one of renal disease. The disease progressed rapidly; he suffered from laryngeal, and then from cardiac symptoms. Dr. Lyons exhibited the kidneys here referred to at a recent meeting of the Dublin Pathological Society.

#### TYPHOID FEVER WITH ENORMOUS ABDOMINAL DISTENSION.

W. B., a man of full age, was admitted into the Hardwicke Hospital under the care of Dr. Lyons, about the fifth or sixth week of his illness. From what could be ascertained of his history, his case was considered to be that form of typhoid fever, in which the fever in the first instance is comparatively insignificant, and in which the enteric lesion is not brought into activity for several weeks after the primary attack. On admission he was found to labour under great depression, and without entering into minute details of his case, it may suffice to say that its principal phenomenon was intense pain of the lower half of the abdomen, and distension of the whole abdominal cavity to such an extent as had hardly ever before occurred in Dr. Lyons's experience. He was placed under appropriate treatment, but died unexpectedly, and Dr. Lyons considered it desirable to make a post-mortem examination. On opening the abdomen there was an escape of noxious gas, and on proceeding further the intestines were found to be enormously distended. The colon was very large; the small intestines were also largely dilated; and they forced up the colon before them to a great height, so carrying the cæcum from its natural situation that it was dragged a couple of inches above the point at which it ought to have been found. It may be well to mention here that one chief object which Dr. Lyons had in making the post-mortem examination was to determine whether, under similar circumstances in similar cases, it would be possible to afford mechanical relief from without during life. With this view he performed an operation on the dead body in order to get access to the cæcum at the portion which lies uncovered by peritoneum, but failed to reach the intestine, in consequence of its abnormal position, as already detailed. Dr. Lyons was not aware that this operation had before been performed in the human subject with the view of relieving unnatural intestinal distension from without, but he stated that such had often been resorted to in the lower animals, with a like object. He mentioned a case of a similar kind to that now under consideration, in which a female had been taking for six months a large quantity of alum daily, with the view of preventing excessive hæmorrhage at her ensuing confinement. In that case the abdomen reached an enormous amount of distension. The next case which occurred to Dr. Lyons's memory was that of a man, who having been under medical treatment for a fortnight, suddenly turned towards the wall, and shot from his mouth a quantity of matter which reached almost to the ceiling of the room in which he then was. He died on the spot, and, in Dr. Lyons's opinion, from rupture of the intestines. In this last mentioned case the intestines were also enormously distended, and no post-mortem examination could be had. It was, however, observed that the arch of the colon was of immense size, the smaller intestines were also much swollen, and there was a large quantity of gas in the peritoneum. In the typhoid case, as before stated, the patient died unexpectedly, and the post-mortem examination (the details and facts of which we have above given) discovered a

quantity of typhoid deposit in the solitary glands; and ten or eleven inches lower down there was a large amount of deposit in the glands of Peyer, which, in Dr. Lyons's opinion, affected the tone of the intestines, and so led to the generation of the large quantity of gas already noticed. The length of time which this man lived in a state of disease before his admission to hospital (five or six weeks), was also noted by Dr. Lyons, who stated that the man's friends had not considered his case at all serious, previous to his admission as above referred to. Dr. Lyons exhibited the morbid specimens in this case to the Dublin Pathological Society at a recent meeting.

### THE MEDICAL ASSOCIATION

OF THE

#### COLLEGE OF PHYSICIANS, IRELAND.

The Association met at the College, in Dublin, on Thursday evening, 4th of April, to discuss the Dublin Hospital Reports respecting cholera, which had been read at the previous meeting. There was a very large attendance.

The PRESIDENT OF THE COLLEGE in the chair.

The PRESIDENT said that since the last night of meeting a very important report had reached Dublin of a singular outbreak of cholera in the city of Utrecht, in Holland, which had been submitted to him by his friend Dr. W. D. Moore, with a short abstract; and it was the opinion of the Council that, looking at the great importance of this report, which gave an account of an outbreak of cholera in many respects analogous to that at Mountjoy Prison, recorded by Dr. McDonnell, it would be desirable, if Dr. Moore would be kind enough to initiate their proceedings by the reading of that report. Dr. Darby had also a report of the outbreak at Bray, but he would incorporate the matter of it in his speech that night.

Dr. MOORE then read the following:—

Mr. President,—Two or three days ago, I received from Professor Donders, of Utrecht, the loose sheets of a recent number of the Dutch "Archives of Medicine," in looking through which I met with an interesting account, by Dr. Snellen, of a very remarkable outbreak of cholera, which occurred last year in a limited district of Utrecht, during the prevalence of that disease in an epidemic form in the city at large. It appears to me that this epidemic within an epidemic, if I may so speak, presents some points of resemblance to the very remarkable outbreak which occurred last December in the Mountjoy Prison, and which has been so ably described by Dr. McDonnell, and that it might be profitably taken into consideration in connexion with the report from the prison already in the hands of the members of this Society. I have, therefore, made a very short abstract of Dr. Snellen's communication, which, as you, sir, and the Council have kindly permitted me to bring it forward on the present occasion, I shall now read for this meeting.

LOCAL EXTENSION OF THE CHOLERA EPIDEMIC, UTRECHT, 1866. BY DR. H. SNELLEN.

Abstract of the above paper from the *Nederlandsch Archief voor Genees en Natuurkunde*, 1866, Deel 2. Aflevering 4. By W. D. MOORE, M.D. Dub. et Cantab., M.R.I.A.

The first case of cholera occurred in Utrecht (the population of which is about 60,000) on the 6th April, 1866; the second on the 21st of the same month. The subsequent numbers were, up to the

11th June	...	...	...	224 cases.
11th July	...	...	...	1734 "
11th August	...	...	...	2221 "
The middle of September	...	...	...	2400 "

In the Gasthuis-steeg (Hospital Lane), the seat of the special outbreak now under consideration, the first case occurred on the 11th June, the last on the 6th of July. Seventeen per cent. of the population were attacked, and ten per cent. carried off by the disease. The course of the local epidemic extended over twenty-five days, before or

after which time not a single case occurred, although in other parts of the city cholera was met with from April, and continued to rage in the middle of September, the date of Dr. Snellen's paper.

The Hospital Lane is a passage connecting Bilt-street and the White Lady Counterscarp, and running from the north-east to the south-west. Its length is about 150 yards, its average breadth is only four yards, while, according to the building regulation, it should be at least eight yards. It is not a public way, the thoroughfare being in general closed against carriages. It contains, including the three courts connected with it, seventy-five houses, all of one story; eighty-three families, and 380 inhabitants.

The author enters into details respecting the several houses invaded by the disease, and their relation to pumps and privies, to follow him through which would occupy too much time. On the plan annexed to his paper the number of inhabitants in each house is represented by a corresponding number of circles, plain in the case of those who escaped the disease, black in the case of those attacked by it, and black with crosses annexed to represent patients carried off by cholera. The plain circles with crosses annexed, of which there are, I believe, only two in the plan, represent individuals who died during the twenty-five days, of other diseases than cholera: the plain circles outside the houses represent more recently arrived inhabitants; the pumps are marked by a double circle and an appendix; the privies are evident, the grates of sewers are marked by shaded parallelograms, the date connected with each patient indicates the period of his or her attack.

It may be well to quote a couple of examples to show the apparently capricious nature of this invasion of cholera. The author says:

"It was a meritorious work of the *Society for the Improvement of Dwellings* to purchase and considerably to improve the first block of houses, which was in by far the most wretched state. These four houses (148a, 149a, 150a, 151) were then raised some feet, as was the yard behind them, and good drainage was secured. We find here one good pump and two privies. The adjoining block—152-155—continues as low as before; the yard behind it is in general a pool; there is one privy, which does not deserve the name.

"It is remarkable that in the first block—in the now good houses—among the twenty-two inhabitants, four cases (eighteen per cent.) of cholera occurred, while on the other hand, in the block of unimproved houses, among the seventeen inhabitants, not a single case was met with.

"It now remains to examine the largest block of houses (166n to 166pp)—a block which has acquired a sad celebrity, inasmuch as thirty-two cases of cholera have occurred among 106 inhabitants—that is thirty per cent. Of these thirty-two cases, twenty-three proved fatal; *twelve times more* cholera having occurred in this locality than had, on an average, at the time (in the beginning of July) visited the whole city. (In the beginning of July cholera had attacked 2.5 per cent., at the close of the epidemic four per cent. of the population.)

"It seems important to examine this block of houses accurately. We here find twenty-one houses, all of one story; twenty of them harbour each only one family. The houses appear to be well built, and are comparatively well kept. Each dwelling consists of two apartments and a garret. Front and rear we find in each house a door and a window; there is consequently abundance of light and air. Behind these twenty-one dwellings is a common yard, in which, along the houses, is a lane or trottoir, to which I shall revert; along it is a row of linden-trees; the further part of the place serves as a bleach-green. The inhabitants belong (or rather for a considerable number of them belonged) by no means to the pauper class.

"The great mortality here attracts our attention still more, when we come out of the immediately adjoining Stevens' foundation. The Stevens' foundation is separated from the Hospital Lane only by a wall. In it 260 persons dwell in 50 houses, here only one fatal case occurred, and that in the person of a woman, who had been, just before,

day and night in the family of her son, where three persons were lying at the same time in cholera. In other parts, too, of the neighbourhood of the Hospital Lane, comparatively little cholera was seen at that time."

Behind these dwellings we find seven privies, they are in comparatively good order; they discharge into a channel which runs along the wall behind the bleach-green, to the moat. Into this same channel the privies of the Stevens' foundation empty themselves. We find here two pumps, yielding clear and well tasted water; to these pumps we shall revert.

Of the 380 inhabitants of the Hospital Lane 170 were of the male, and 210 of the female sex; 28 men and 35 women were attacked by cholera; that is of the men 16 per cent. and of the women 16.5 per cent. This is indeed a remarkable equality for the two sexes. The inhabitants are all industrious working people, earning 10s. to 16s. a week.

"In former epidemics there were attacked in this district, in 1832, 2 cases, in two dwellings; in 1849, 22 cases, in 9 dwellings; in 1859, 2 cases, probably in 1 dwelling; in 1848, no case occurred, nor in 1853, 1854, and 1855. In 1866 the total number of cases was 63 or 16.6 per cent. of the population, while the deaths were 39 or 10 per cent.

The question, observes the author, rises to every one's lips:—"Whence in this case the local violence of the epidemic, so extremely limited in time and space, running its course in twenty-five days, confining itself in its immediate vicinity to one street?"

To answer this query would be, he further remarks, to answer the general question: "What is cholera, and whence comes it?" It is certain that in the Hospital Lane no special causes are discoverable, and the phenomena observed in connexion with the first appearance of the disease are precisely the same as have been witnessed in a great number of other points of the city.

On this subject the author endeavoured to throw light by experiments upon animals. In contrast to former statements, he did not succeed in conveying the disease to them. He tried dogs, an ape, a pig, rabbits, hens, frogs, and fishes.

The principal questions connected with the spread of cholera are:—

*Is the infecting matter transmitted through the air?*

*Is the earth the conductor of the contagion?*

*Can direct transference from the sick to the sound exist?*

"The cholera proceeds from one sick individual and infects others." As to the truth of this proposition all are agreed. It has been satisfactorily demonstrated that the disease arises epidemically in no place where it cannot be conveyed by the sick, or by what was in contact with the sick. But how further? "Through the air?" Many think so. On this point the author proceeds to quote the International Sanitary Conference at Constantinople, and also the views of Pettenkofer. In his own opinion *it is, exclusively the digestive organs by which the infecting matter enters the body.* In support of this view he examines in detail the pumps and privies in Hospital Lane, and concludes his paper in the following words:—

"We have in vain sought for any fact plainly at variance with the proposition that the cholera miasm must be received exclusively in the digestive organs. We are convinced that the hypothesis of the transmission of the contagion, not through the air, and not through mere contact, removes the difficulties always correctly adduced against the former idea of the contagiousness of cholera.

"It is true that the final cessation of the epidemic is difficult to explain: why does it not always continue? This difficulty, however, cholera presents in common with all epidemic diseases, as well as with the diseases of plants and animals.

"Every investigation as to the influence of atmospherical causes upon the advent and departure of the epidemic has hitherto afforded only negative results. Only it would appear that much rain favours the decrease of the disease. It is certain that the rain washes away and washes out much. In the night between the 29th and 30th of June, in the course of about eight hours sixty-five million gal-

lons fell on the surface of Utrecht ; as much as if each of the inhabitants had on that night employed fifteen or sixteen gallons in washing the ground.

"It is more than probable that in cholera, as in all other diseases, the individual influence of receptivity exists : the same injurious agency, which produces cholera in one, will probably in another develop only choleraic diarrhœa.

"We may reasonably hope, that individual receptivity will diminish, if we proceed energetically in the beaten way : 'providing for good drinking water, for the improvement of the food of the people, for the promotion of cleanliness, and for the removal of injurious filth, for the improvement of dwellings,' and not less 'for the investigation of endemic diseases.'"

Dr. DARBY said he had not originally the slightest intention of making any report of what had occurred in the hospital under his care until he heard the reports which were read on the last evening, and those reports being so very different in their results, he thought it right to take an opportunity of mentioning the facts which had come under his own observation, and which he had publicly recorded. He had, between the 28th of September and the 28th of December last, 61 cases of what he had entered in his registry as cases of cholera, and out of which he had only 17 deaths. Now, when he heard the reports read the other night, he thought he must have made a great error in entering those cases, or many of them, as true cases of cholera ; but he came, on considering the matter, to the conclusion, that the gentlemen who had made some of the reports from the large Dublin hospitals were at issue with him as to what cholera was. One gentleman stated that he did not regard as cholera any case that had only purging, vomiting, and cramps. Now, he had recorded cases as cholera that had only purging, vomiting and cramps, with peculiar expression of countenance. If such cases were not to be regarded as instances of true cholera, then he was altogether at issue with some of his medical brethren, and he thought the statistics of the disease obtained from the country dispensaries generally would be very fallacious. He did not think that a case of purging, vomiting, and cramps during an epidemic of cholera could be considered as any other disease but cholera. He was actively engaged in 1832 as a pupil attending cholera cases that occurred in Dublin ; and ever since that he had been engaged in the treatment of cholera cases on every occasion when the disease appeared in this country ; and he would say this, that he had never seen what was called English cholera—that disease met with in the latter end of summer or autumn, and which they were in the habit of attributing to the eating of fruits or fresh vegetables—he had never seen that disease as an epidemic in his life. He thought when an epidemic of cholera was present, and a patient was attacked with purging and vomiting they had no option, but must call the case one of cholera. Take any other disease that was an epidemic, scarlatina or typhus for example, and if they excluded all malignant cases, and took nothing but the mildest types of it, they would see what an alteration would be made in the average of mortality. He saw no difference between English cholera and Asiatic cholera, but that one appeared sporadically, and the other as an epidemic. He did not know what people meant when they spoke of choleraic diarrhœa. He had seen diarrhœa when cholera was present, but that it was different from diarrhœa, properly so called, when cholera was not present he could not perceive. Again, if it were said that cholera depended on a certain poison, and if it were said that when a person was attacked by diarrhœa that would, if unchecked, run into cholera, which was the generally received notion, what followed? Was it not clear, if diarrhœa runs into cholera, and if cholera depends on a poison, that the man who had the diarrhœa must have been poisoned in the first instance? Was it not a poison, if there be a poison, that gave the diarrhœa? He had dwelt on this point to justify his own report. He should not wish that any one would suppose for a moment that he would exaggerate the results of his treat-

ment, or call a case one of cholera which he did not believe to be cholera; and if he did not give an explanation of this kind, it might appear either that he was presumptuous enough to suppose that he could cure patients in a greater proportion than the greatest physicians in the land, or that he was altogether ignorant of what cholera was. He had divided the total of 61 cases received into the Rathdown Hospital, from the 28th of September to the 28th of December inclusive, into three classes—viz : Males above 10—Females above 10, and children of and under ten years of age. In the month of September there were two males and two children, and one male died. In October five males, thirteen females, and nine children—a total of twenty-seven. There were two deaths of males, two of females, and three children, making a total of seven deaths. In November six males, nine females, seven children—total twenty-two—the deaths were one male, two females, and two children—total five. In December two males, three females, and three children—total eight. The deaths were two males, one female and one child—total four. He had further divided the patients into mild and severe cases, meaning those that did not go into collapse, and those who did. Thus seven males, nine females, and several children, making a total of twenty-three cases, were admitted to hospital in a state of collapse. Of the thirty-eight who were at the time of their admission not in that stage, seven went into collapse and thirty-one pursued a mild course. The youngest child who died was only four months, the oldest man was seventy years.

Dr. MACSWINEY said—The five Dublin reports, of which the "abstracts" were now before the Association, and which they might expect to see in a short time published in a full and complete form—must be regarded as important documents, embodying the experience of skilful physicians, and containing a very large and varied amount of information respecting the recent outbreak of epidemic cholera. And, if the value of the facts contained in these reports were not as great as it might reasonably be expected to be—and he thought that this was the case—he ventured to say that the explanation would be found in the circumstance that one condition, essential to the full success of such reports, was not adopted at the outset. He alluded to a fixed uniform basis of tabulation, under the several "heads" of which could have been clearly catalogued the different items in each report. Had this been done, they would now have had before them a means of observing, at a glance, the several facts stated and conclusions arrived at, each under its proper designation ; and he believed that, in that way, great additional worth would attach to the reports. As it was, he feared it would be difficult to extract, and present, in a condensed form, the full value of all the information contained in these documents. The principal points respecting Asiatic cholera requiring to be elucidated may be stated to be—

Its nature, (including the question of contagion).

Its best treatment.

Its best preventives.

Its present death-rate.

He had analysed the "abstracts" with a view to discover what help towards advancing our knowledge upon these points might be derived from a study of them. The following short table would show, in his opinion, that an error, fatal to the full usefulness of these reports, was made in not originally basing them upon a common foundation, where an uniform shape and nomenclature would be used :—

Hospitals.	Admitted.	True Cholera.	Premontory.	Diarrhœa.	Purging.	Vomiting.	Vomiting and Cramps.	Collapse.	Consecutive Fever.	Death rate per cent.
Mater Misericord.....	197	—	—	54	—	—	—	124	—	53.8
Meath.....	130	—	8	—	—	—	—	117	5	51.5
Dun's.....	180	—	—	—	142	130	84	74	—	47.2
Hardwicke.....	277	193	—	68	—	—	16	—	—	66.3
Mountjoy.....	9	—	—	4	—	2	—	1	—	44.4
Total ...	793	193	8	126	142	132	100	316	5	

This Table might be greatly extended in the same direction. It was not necessary to indicate, in detail, what it shows; he would merely remark that the terms placed over the several columns were those employed in the Reports; an inspection of it would at once point out the nature and grounds of his objection. An adherence to a common plan would also, probably, either prevent the following discrepancy between the statements in two of the reports, or else explain the cause of such a singular difference in the experience of the two hospitals.

"The earliest cases of cholera were by far the most fatal."  
—*Dun's*.

"The earlier cases were more amenable to treatment; while, as the epidemic advanced, the disease assumed a more malignant type."—*Meath*.

As to the treatment, he did not think any certain, or exact conclusion could be arrived at from a study of the allusions to the very numerous remedies contained in the "Abstracts." Perhaps the reports, when published in full, might contain some more precise information on this point than was indicated in the "Abstracts." He assured them that he made those remarks in the interest of science alone, and that he was fully sensible of the great amount of important facts and observations detailed in these valuable reports.

Dr. LYONS said they all knew that in cholera epidemics there was a vast difference in the mortality in different portions of the country. He could not agree with the last speaker that it would have been of advantage to tabulate the cases from a common point of view. He thought by the method adopted they had derived much more satisfactory information than if they had obtained it in accordance with one uniform plan. Presently he would have to suggest a mode by which the data collected might be reduced to a uniform standard. He thought it might be useful to state what the exact data of mortality was as recorded in other epidemics. During the epidemic of 1848-9 in England, the cholera destroyed 85 in 10,000 inhabitants in low sea-side districts; in inland towns it was fatal to 38 in 10,000 inhabitants; in London to 62 in 10,000, and in country localities near small streams to 12 in 10,000 inhabitants. The general average of deaths for England was 30 in 10,000 inhabitants, the total deaths for all England in 1849 being 53,292. Now calculating on such data, the late Dublin epidemic was fatal in the proportion of 40 in 10,000 inhabitants. Some other data of interest might be derived from the facts before them as compared with the facts of other epidemics. In England in 1849 the co-efficient of invasion of the disease or its power of extension will be found to have been for all attacked 0.95 per cent. of the whole population. In the remarkable epidemic at Utrecht brought before them that evening, the per centage was 9, a most extraordinary amount. In Dublin, in 1866, the co-efficient of invasion was about 0.90: in the Hardwicke Hospital in that year it was 1.43, but if the whole population of the three hospitals of the House of Industry were taken the co-efficient of invasion amounted to 0.45 per cent., showing a very important bearing on the question of contagion or non-contagion; because it showed that in a population peculiarly exposed to influences that might be supposed favourable to the propagation of cholera by invasion, the tendency to spread to individuals was 0.45 per cent., which was less than half the co-efficient of invasion in England in 1849, and considerably less than that which the disease exhibited for the total population of Dublin which reached 0.90. There was admitted to the Richmond Hospital a patient with fracture of the humerus who developed cholera, was moved to the Hardwicke Hospital and died, but the disease did not spread within the walls of the Richmond; there was constant intercommunication between the attendants of all three hospitals. It would be seen that while generally the mortality and co-efficient of invasion were high in the city during the epidemic, the co-efficient of invasion was certainly low in the hospitals taken altogether. It might be asked, were we at the beginning or at the end of a great cholera wave? In his opinion, we were at the beginning, or rather in the interspace between two

great waves. What was the practical lesson they should derive from this? He should say, in broad terms, sanitary agitation or agitation for sanitary reform in the city. Much had been done in this way, but a vast deal more remained to be done. What lesson was to be derived from the result of the admission of cholera cases into the general Hospitals? He believed the results showed that it was useful, and at the same time safe for persons suffering from cholera to be received into the general Hospitals, and that it was greatly to be desired that facilities for their reception into all general Hospitals should be increased, and further more that local Hospitals for the treatment of the disease should be established, as far as possible, with a view of having patients received at once and treated immediately. Dublin was a natural home for cholera, and much remained to be done to render the city less liable to the invasion of the disease. Our river required to be cleansed, our sewers to be attended to, our streets to be purified, and better provision made for the disposal of our household and domestic sewage. He thought there was a great deal of valuable instruction to be derived from the Hospital reports which had been read. They showed in a logical manner against the conclusion that the disease was capable of being spread by contagion, and furthermore that contagion must be necessarily excluded if we take into account the argument, which the time at his disposal would not enable him to develop, to be drawn from the co-efficient of invasion of the disease as exemplified amongst our own population, or the special and limited population of the Hospitals, and as compared with the spread of the disease in other circumstances and in other towns. With regard to the question of contagion, they must argue logically from contagion to quarantine. Now it had been fully established that quarantine was totally incapable of excluding the disease; it would over-leap all the bounds which quarantine in its most stringent form had been able to establish in the shape of a cordon. Quarantine meant exclusion, stoppage of commerce, passenger and other traffic, and would be quite impracticable in these countries. Fancy a gentleman coming over here in the Holyhead steamer, and finding the police standing on the quays to prevent his free debarkation, which they knew to be so common a means of attempting to check the introduction or propagation of the disease in cities and districts where ultimately epidemic disease of every kind had been known to spread.

Dr. HAYDEN begged to remind his friend Dr. Lyons of two notable instances of protection afforded by quarantine against the invasion of cholera. During the late epidemic of cholera in the Mauritius, as reported in an admirable memoir, recently laid before the Cork Medical Society, by Dr. Hardie, Surgeon 73rd Regiment, whilst that island was being decimated by the disease, not a single case occurred in the adjacent island of Réunion, which was in the possession of the French, and protected by quarantine. Again, whilst the cholera epidemic of 1866, travelled along the European coast of the Mediterranean, it respected Sicily and Greece, both of which were protected by quarantine. As regarded the general question under debate, it seemed to him that one of the most remarkable properties exhibited by cholera, in common with all other epidemic diseases, was that of occasionally transgressing the limits that ordinarily confine its operations, and devastating regions far beyond the limits of its endemic habitat. To what is this due? Is it the result of a concentration of the specific poison in the atmosphere, to saturation point, and its consequent diffusion by the convenient channels of outlet afforded by commerce and human intercourse? or is it that the atmosphere of certain portions of the earth's surface, commonly unfavourable to cholera, undergoes, at certain times, and under the influence of some unknown cause, changes favourable to its reception and development, and requiring only the introduction of the specific morbid poison to develop the disease in all its potency? Whatever the opinion upon this subject may be, it is all but certain that cholera is conveyed between distant places *only* by man and his articles of dress, furniture, traffic, &c.; and, sir (continued

Dr. Hayden), I deem it no less certain that it is contagious, or communicable from the infected directly to the uninfected. The *media* through which, contamination is effected in the majority of instances, I believe to be the air breathed, and the water drunk, and containing in either case, in suspension or solution, the specific poison of cholera, which thus finds entrance into the circulation by the lungs or alimentary canal. In regard to water, I believe the communication of cholera through this medium is not so well established as it is in regard to atmospheric air. Indeed, I rather incline to the opinion that in most instances of alleged communication of the disease by the water drunk, the latter, being simply of an unwholesome character, has acted rather as a predisposing than as an exciting cause of the attack. As the question of contagion is that upon which the most marked difference of opinion exists in relation to cholera, I will, sir, with your permission, devote the few moments that remain to me, to the discussion of this portion of the subject, reserving for another place the consideration of it in its several departments. It is noteworthy, as bearing upon the subject of contagion, that cholera has never yet been proved to travel faster than man; whereas, in innumerable instances, it has been demonstratively shown to vary with the rate of man's progress. As facts are more convincing than mere assertion, I will take liberty of submitting to the society the two following examples of communication of cholera by contagion. One of these came under my own cognizance; and for the particulars of the other I am indebted to a medical friend in this city, who vouches for their accuracy:—

Mrs. G., a woman of middle age, and in the enjoyment of comparatively good health, came up to Dublin from a remote part of the county Meath, on the 5th of November last, for the purpose of having her infant, ten months old, operated on for club-foot. She was admitted into the Mater Misericordiae Hospital on the following day (6th) and placed, with her child, in the female surgical ward. On the morning of the 13th November she was seized with cholera, and at once transferred to the female cholera ward up-stairs, having continued to suckle her infant up to the moment of her removal. She died of cholera on the evening of that day, the infant continuing unaffected then and subsequently. No little uneasiness was felt lest this woman had contracted cholera whilst in the hospital, and the disease was about to spread amongst the patients generally. The most searching inquiry was accordingly instituted, with the view of ascertaining whether she had been at any time in the neighbourhood of the cholera-wards; in contact with the cholera-patients; or in any way, directly or indirectly, exposed to contagion whilst in the hospital. The result was the conviction that no such exposure had taken place; the woman had not once gone beyond the corridor adjoining the female surgical ward, which is on the second floor—the wards appropriated to cases of cholera being on the third floor, and quite remote from the former. Both wards had separate attendants and implements, and the most scrupulous care was taken to guard against the communication of cholera by those on duty in the infected wards. It is to be remarked, also, that the woman G. was the only inmate of the ward which she occupied who was not suffering from disease or accident of some kind, and that the surgeon in charge of her child had no contact with, or relation to, the cholera cases. On the 16th November the husband of this poor woman came to Dublin, and in a conversation with one of the sisters of the hospital stated, that on the night of his wife's arrival in Dublin, she slept in a lodging-house where cholera had recently been, and expressed the opinion that she there took the disease. On inquiry, it was ascertained that the house in which the woman had slept was 20, Greek-street, and that in that house there had been a case of choleraic diarrhoea late in September, and in the adjoining house, No. 21, no less than five cases of cholera in September and October, whilst that street (Greek-street) yielded, probably, a greater number of cases of cholera than any other street on the north side of the city. It would, therefore, appear that this woman received the cholera-

poison in that lodging-house on the night of the 5th November, and developed it in the hospital during the week between the 5th and 13th November. It is impossible to arrive at any other conclusion than this, and I would respectfully ask the gentlemen who advocate the view that cholera is not contagious, to say, whether, if evidence equally strong had been furnished in regard to the communication of typhus fever, scarlatina, or any other admittedly contagious disease, they would hesitate to declare that the disease in question had been then and there contracted by contagion? A medical friend, in large practice in Dublin, has furnished me with the following particulars:—An old lady and gentleman, friends of his, came up to Dublin in August, 1849, from a remote part of the country, where cholera had not appeared, in order to spend some weeks at the sea-side; they took apartments at Blackrock, and on the morning after their arrival my informant was hastily summoned to attend the lady, who was reported seriously ill; he hired a car at the railway-station to drive him to his friends' lodgings, on approaching which the driver significantly remarked that a person who had died of cholera had been removed for interment from that house on the morning of the previous day. The lady, who occupied the same apartments as the person who had died of cholera the day before, there being no others to let in the house, had a severe attack of cholera, from which she was convalescent, when her husband communicated to her the startling intelligence that he too was attacked by cholera, in consequence of which she had an apoplectic seizure which carried her off. The husband ultimately recovered, after passing through the stages of genuine cholera, but a servant of the house, who was subsequently attacked, died of that disease. I might multiply examples of this kind, did the time allowed for addressing the Society admit of my doing so.

Dr. MOORE, F.K. & Q.C.P., said that during last autumn he was engaged with Dr. Kennedy in treating cases of cholera in Sir Patrick Dun's Hospital, and his idea was to check the diarrhoea as the best way of dealing with the disease in the first instance. If all cases of vomiting and purging, without cramps, were excluded, the per centage of mortality would have been much greater. He found the mortality in the Hardwicke Hospital was 66 per cent., in Dun's Hospital 47 per cent., and in the cases which occurred under Dr. McDonnell, the mortality was under 50 per cent. He asked how was this to be accounted for; and he found on inquiry, that it occurred exactly in the way he had expected. The provision made for the epidemic of cholera, under the Poor-law administration, completely fell through. On the south side of the city 28 beds were opened for cholera patients. A rush of cholera came on. Eight beds additional were opened in Dun's Hospital; but there was a limit to this, and the result was that the accommodation provided was insufficient. Cases were brought to the Meath Hospital, but could not be received; they were then taken to Dun's Hospital, but when that, too, was full, they were sent on to the Hardwicke Hospital, where they arrived in a moribund condition. If ever we were afflicted with another visitation of cholera, he believed that if a house to house visitation were adopted, all the general hospitals opened, and temporary hospitals established in different parts of the city, the most satisfactory results would follow. He thought what he had stated was a strong argument for the adoption by the authorities of more active and decided efforts, in a sanitary point of view, to check the epidemic.

Dr. HENRY KENNEDY began by saying he was a non-contagionist; and he said so, though aware of the many arguments, some of them very forcible, which had been advanced on the other side of the question, and, more particularly, he must advert to the very elaborate paper, or rather essay, by the late Dr. Graves, which had appeared first in the Dublin Journal, and, subsequently, in another form, had been transferred to the volume of "Physiological Essays," written by Dr. Graves, and edited by Dr. Stokes. Dr. Kennedy thought that, in the consideration of this question, several points had been overlooked. He then

went on to say: "Several years back, whilst investigating the subject of epidemics, I was struck by the fact that all those which had traversed a large portion of the globe travelled in the one direction, that is from east to west, or from south-east to north-west. This appeared to me of such importance that I had a chart printed of these epidemics from the earliest periods, and brought it before the Royal Irish Academy. It shows that ages ago, when human intercourse must have been vastly less than at the present day, epidemics travelled as they had done of late, and of which the cholera in each of its invasions afforded a very good example. It also proved that the epidemics affecting cattle travelled in the same way, and the cattle-plague of last year was an example of this kind, having come to Great Britain from Russia. As an evidence of what may be deduced from the chart, I may mention that in the great epidemic fever of 1847-48, it was the fashion to speak of Ireland as being the originator of the disease. Now this was a mistake. Fever had existed in England far above the averages, and for months before it reached this country. Nor was this the first occasion on which a similar event had occurred. But further, and still speaking of the question of contagion, I would observe many seem to think that because an epidemic occurs, it must therefore be contagious. Two, three, or more cases have arisen in one house, within a brief period of each other, or it may be one room, and the conclusion is hastily jumped at that the spread of the disease, whatever it be, must be due to contagion. Now, on this point I would ask—Is not the occurrence of cases in such rapid succession opposed to any real knowledge we possess of the laws of contagion? Have we any reason to suppose that a few hours are sufficient, not only to generate, but to bring into active life, such a disease as cholera? Are not the cases too frequently simultaneous? and will they not thus prove more than even contagionists demand? In support of these views I would further mention a fact with which all who have had charge of a large hospital must be quite familiar. I mean the sudden appearance of a disease in a single night. Thus, three or four cases of erysipelas will occur within a certain twelve hours, or an invasion of laryngitis, or otitis, or pneumonia, or a number of the patients will all be found worse on the same morning, when there was every reason to have expected the contrary from their state the previous day. All these considerations and facts—and they could have been easily added to—have ever led me, when speaking of the contagion of cholera, to look upon what I would call negative evidence as by far the most important which could be adduced on the question. Now, of this kind of evidence there are, I believe, more numerous facts than have ever been brought forward about any other disease, in which the question of contagion arose. By far the greater numbers of those who have seen the disease in India are non-contagionists, and the scale on which they have seen the disease entitles their opinions to the greatest weight. Again, the late Dr. G. Kennedy told me he had been sent down to Galway in 1832, and that if ever an opportunity offered when contagion might have been expected to have played a prominent part, it was then; that the town was very severely visited; and the people taken quite unprepared; that houses, nurses, and every requisite had to be got at a moment's notice; and yet with all this the nurses escaped. Dr. Byrne, of the Lock Hospital, who was also sent down then, can confirm this statement. The result, too, of the last epidemic in Dublin also bears out these facts, for the attendants at the several hospitals may be said literally to have all escaped. Neither can I omit noticing the fact that cholera, of all diseases, brings the nurse and the patient into the closest contact. If cholera be contagious, it is little short of marvellous to explain how so many escaped. When epidemic fever visited us in 1847-48, every new nurse at the Cork-street Hospital, where some six hundred beds were open, took fever within a month of their appointment. Before sitting down, sir, I wish to say one word in reference to the treatment. I believe a mustard emetic to be often a very

valuable resource; and I think I have had enough of experience to enable me to speak with some confidence on the point. Want of time, however, prevents me giving my reasons for this mode of treatment, which, of course, is not new. In conclusion, I wish to speak of two points bearing on the prognosis. Every one who came in contact with cholera must have met cases where the question of life or death became a very difficult one. They were usually pulseless cases, as far as the wrist was concerned, and they would live in this state for many hours, or even days. In such I observed that, if they were going to die, puerile respiration declared itself, and seemed then to be a sure precursor of death; and, again, I found that one of the sounds of the heart would, under similar circumstances, be lost. Contrary, however, to your observations, sir, on the heart in fever, it was the second sound that was lost, as, indeed, the most plausible explanation of the fact would lead us to expect; for, I believe, both the state of breathing I have spoken of, and the loss of the second sound were directly due to the state of the blood in these patients. It had ceased to circulate, or nearly so; and, as long since shewn by Sir D. Corrigan and others, the valvular sound of the organ, that is, the second, must necessarily then be lost."

Dr. DAVYS said he had come there to hear if there had been any new and efficient method discovered of treating cholera. He had heard a great deal of statistical facts, which he might have obtained from the returns of the Registrar-General, and he had heard some discussion as to whether cholera was contagious or non-contagious, but except what fell from Dr. Moore, he had heard nothing as to the treatment of cholera. No more dreadful scourge had ever visited this country. In his own district, from the 7th to the 29th of September, there had been at least thirty cases. He had seen it attack persons in a good condition of life, and persons in humble circumstances, and if more than ten minutes were allowed him he could prove that cholera was contagious. But what he wanted to know was, whether there was anything new in the treatment of cholera. He himself had tried with cholera patients everything he had heard of, and in no three cases had the same method of treatment succeeded. He had tried castor oil and found it good on some occasions, while it failed on others. The ordinary mustard emetic had succeeded with some, and failed with others. He therefore hoped to hear something of importance as regards the successful treatment of the disease, which he regretted to learn was, in the opinion of Dr. Lyons, likely to revisit this country.

Dr. LAING, Staff Surgeon-Major, said he was stationed in Kurrachee in Scinde, in the month of June, 1848, where all communication was cut off by sea from all parts of the Continent, and little communication by land existed. Cholera came on on the 14th of June, and in the first twenty-four hours 100 men came into Hospital. It appeared as if a cloud came across the sun, and at six o'clock that evening the men began to come into Hospital, and before seven o'clock there were thirty men lying dead. The disease went on for ten days, and in that time they lost 240 men. He ought to have said that no rain falls in that country; the dew point was very high, there was very little difference in the wet and dry bulb, and there was a constant breeze blowing from sea which kept the air moist. The regiment he belonged to had had a great deal of hard work, and had returned to this place, and were in tents when the epidemic broke out. The other regiments suffered not so much, but they lost a good deal of men also. The men suffered dreadfully, but of the officers in the cantonment only one was attacked, and he recovered. Another officer on the station was attacked and died. The atmosphere was most oppressive. It was a remarkable fact that the brahimine, kites, and crows, which collected about the cantonments to pick up the offal, disappeared altogether, and did not return until all the cases of cholera had ceased. The domestic fowls about the cantonment died, and he was told that the sheep in the neighbourhood suffered severely. The disease left them and went up the river Indus, and gradually appeared to lose itself in the upper country. The dakrunners were stricken down on the road, and found lying there dead. Every mode

of treatment was tried. In the first thousand cases of disease there were seventy or seventy-five deaths, and as the disease proceeded towards its termination the mortality diminished. He had since observed the disease in Bengal, and it broke out there under different circumstances. It appeared about three weeks after the monsoon. The rainfall at the beginning of the monsoon clears the atmosphere, and a fortnight or three weeks after the rain ceases to fall, the air becomes close and oppressive, and it was then they looked out for the appearance of the disease. The moment a case of cholera or diarrhoea appeared, the regiment was moved across the Jumna river, and not a single case of cholera occurred in the six companies, which were thus moved. Diarrhoea, he was perfectly certain, ought to be counted as a concomitant of cholera. He thought every case of diarrhoea, during the prevalence of a cholera epidemic, ought to be regarded as a case of cholera. He thought the principle acted on in removing a regiment from the place in which it was attacked with the disease might be taken advantage of in Dublin. If an outbreak took place at Donnybrook for instance, if the whole population were moved out of the place, it would save many valuable lives. He approved of the primary treatment of diarrhoea by opium and astringents. When purging came on with suppression of urine and rice-water evacuations, he had found dashing with ice-water to have had more effect than anything he had seen used in the disease. (Applause.)

Dr. QUINLAN said he believed that a great many officers who had served in India, and had experience of cholera on an extensive scale, were of opinion that it was not contagious. Now, as there were several army medical officers of Indian experience present, it would be desirable if they would favour the meeting with their views upon that subject.

Dr. HAVERTY, 52nd Regt., observed that from what he had seen of cholera in India, he was strongly impressed with the belief in its non-contagious nature. He had nothing to bring forward in the way of statistics, but he had directed his particular attention to that point, and such was the conclusion at which he had arrived. In the treatment of cholera cases he always had the aid of the men of the different companies which were attacked with cholera to wait on the patients, and he could not adduce a single instance of a man having taken cholera who had attended on a cholera patient as a nurse. It had been observed a few minutes ago that the nursing in cholera was different from that in any other disease. The men were constantly and closely employed, they were brought into immediate contact with the patients, and if cholera were contagious, one would suppose these were the very circumstances under which the contagion would spread. Yet, so far as his experience was concerned the contrary had been the case. He had seen instances of the extremely eccentric way in which cholera travels. On one occasion cholera existed in a place within sixty miles of where his regiment was stationed, and swept the country in the immediate neighbourhood, and carried off a great number of people, yet it did not touch the cantonment in which he was, although there was a high road between the two places, and constant communication kept up. In the next year cholera attacked the cantonment where he was, and left the city at the distance of sixty miles, and although people were constantly passing from one place to the other, no case of cholera appeared in the latter. Atmospheric influence was much talked of as a means of conveying the cholera in India. In the instance to which he referred the wind was in a direction favourable to the spread of the cholera from place to place, yet the disease passed by some places, and made a jump as it were of sixty miles to another locality. As regarded this cantonment of which he spoke, about ten days after the outbreak took place the troops were moved to a distance of about six miles from their former position, and there also the cantonment was on the high road, about eight miles from a city, where the wretched natives were dying by hundreds, and it was said, by thousands. The cholera ceased in two or three days after they removed to that locality. Some few cases occurred within twenty-four hours after their removal, but it

was probable the men had brought the germs of the disease with them. The disease, however, ceased to spread, and all the time the wind was blowing towards them from the city where the cholera was raging, and there was a constant intercourse kept up with the natives. As regards the treatment of the disease, he was always in the habit of saying that nursing was the only thing for it. He still knew of nothing so effectual as constant attention, the introduction continually and cautiously of nutriment and stimulants, and friction with counter-irritation. It struck him as extraordinary, if the preliminary stage of cholera were ushered in by diarrhoea, why there should be strong advocates for the use of purgatives. He should have thought that their great object would have been to check anything in that direction. Their great object was to get hold of cholera in its early stage, and put a stop to it, and they were successful in doing this. How purgatives could be advocated under these circumstances he was at a loss to understand. Mustard emetics were spoken of as being very useful, but when their object was to check purging and vomiting, he did not see why they should try to induce vomiting by giving a mustard emetic, or any other emetic. (Applause.)

On the motion of Sir DOMINIC CORRIGAN, seconded by Dr. LYONS, the debate was adjourned until the following evening.

#### THE CASE OF WIGHT V. FIELD.

At the meeting held in support of Mr. Field, on the 2nd instant, and to which we called attention in our leader of the 3rd, the following were the resolutions adopted. As already announced, Dr. Copland, F.R.S., occupied the chair at this meeting, which was one of the most successful ever held for a similar object. About 120 of the leading members of the Profession being present.

First Resolution.—Moved by Mr George Sandeman, seconded by Dr. C. J. B. Williams:—

“That this meeting desires to express its sincere sympathy with Mr. Field, for the great annoyance and anxiety to which he has been subjected by the proceedings taken against him in the recent action of *Wight v. Field*, and while congratulating him on the successful issue of the cause, wishes to convey to him an assurance of the undiminished regard and esteem in which he is held.”

Dr. Gibson and Mr. Aikin addressed the meeting in support of this resolution.

Second Resolution.—Moved by Mr. Prendergast, seconded by Dr. Wight:—

“That in order to demonstrate the feeling which this meeting entertains towards Mr. Field, a fund be raised with a view of reimbursing him for the heavy legal expenses which he has been compelled to incur.”

Mr. Hill addressed the meeting.

Third Resolution.—Moved by Dr. Markham, seconded by Mr. Page:—

“That a committee be appointed to carry into effect the object of the second resolution, and that Dr. Langmore and Mr. Curgenvin be requested to act as treasurer and honorary secretaries.”

Dr. Langmore and Curgenvin addressed the meeting.

Fourth Resolution.—Moved by Sir W. Ferguson, seconded by Mr. Probert:—

“That the thanks of the meeting be given to Dr. Copland for his kindness in occupying the chair on this occasion.”

Dr. Copland returned thanks.

#### CURRENT LITERATURE.

A SMALL pamphlet by Dr. W. M. Dobie “On the Use of Chlorine in Asiatic Cholera,” has previously appeared in the *Edinburgh Monthly*. It gives an account of fifty-two

cases that occurred at Chester in the last epidemic. Out of thirty-four treated on the ordinary plans, only eight recovered, while of eighteen cases treated by chlorine, there were ten recoveries. Dr. Dobie considers that chlorine has a decided effect in restraining exudation from the mucous membrane of the bowels, that it increases the pulse, and restores the circulation. The preparation of the mixture is a point of importance in the author's opinion. If chlorate of potash be dissolved in a quantity of water, and hydrochloric acid then added, very little chlorine will be set free, and the mixture is then said to be less efficacious. Should this be found to be the case it would certainly be an argument against the benefit derived, being all attributed to the mineral acid.

The author says :—

"If prepared in the following way, the result is very satisfactory :—

"Take a clear dry wine or brandy bottle, place it for a few minutes upon a hot brick, or upon a stove, until it becomes thoroughly warm, then take eight grains of chlorate of potash in coarse powder, and add to it one fluid drachm, by measure, of chemically pure hydrochloric acid ; agitate the chlorate in the acid until all effervescence ceases, and the chlorate is completely dissolved. Then add an ounce of water, shaking the bottle briskly. Continue thus to add sixteen ounces of water, ounce by ounce, shaking the bottle between each addition. If two fluid drachms of chloric ether be now added, the mixture is complete.

"The chlorine mixture, as thus prepared, is about one-third saturated with chlorine, it can be readily taken by patients direct from the bottle ; but it was generally administered with an equal bulk of water. Three drachms of the mixture are about equal in strength to a drachm of the liquor chlori of the British Pharmacopœia.

"The dose of the chlorinated mixture was half-an-ounce every hour, or every two hours, to an adult ; if the first dose was vomited, another was given after a shorter interval.

"Mr. Brittain chiefly used the liquor chlori of the British Pharmacopœia in drachm doses, diluted with a tablespoonful of water."

Dr. Dobie gives reasons for proposing to add muriate of morphia in some cases, and adds :—

"I noticed that the chlorine mixture had a remarkably sedative action upon the stomach and bowels ; the vomiting as well as the diarrhoea being restrained. My impression is, that the chlorine mixture, with the addition of chloric ether, was better tolerated by the irritable stomach than the diluted chlorine water given alone.

"The pulse, in cases where it was quite imperceptible at the wrist, became in a short time full and strong. The capillary circulation being restored, the surface became warm, and the purplish blue of the skin changed to a more natural hue. The cramps were subsequently less severe. Reaction was seldom violent, and I do not recollect one instance of secondary fever in the cases treated by chlorine.

"The secretions of the liver and kidneys in mild cases were rapidly restored. Another point to be observed is the remarkable comfort it gave to the patients ; the excessive restlessness was much mitigated, and one man said, 'I could not live without that medicine.'

We have received the Report of the Savernake Cottage Hospital, where forty cases have already been treated, of which twenty-one were cured and relieved, nine remain in the hospital, and only two were sent out as incurable. We have thus another example of the success of Cottage hospitals. Another report to hand is that of the Devonshire Hospital at Buxton, which seems to continue its career of usefulness. We observe that a single guinea en-

titles the donor to recommend a patient, but each patient costs £1 17s. 5½d. The charity is also like many others in want of money. Why not make the subscription entitling to recommend two guineas? This would certainly assist.

Mr. Nimmo has added to his handy little manuals one on "Domestic Medicine," written by Dr. Shore, who states in his preface it is intended to show what to do "preparatory to the arrival of the doctor." He adds a protest against too much "doctoring at home," which, so far as our experience goes, is not without need. Indeed, we think that the part devoted to the treatment of diseases may be well disregarded wherever medical advice is accessible. The hints on emergencies, like drowning, bleeding, poisoning, management of the sick-room, preservation of health, diet, regimen, &c., are all much more within the province of treatises on domestic medicine, and we are therefore glad to find a large portion of the book devoted to these subjects.

Two new journals have come to hand, and demand a few words. First, the *Journal of Cutaneous Medicine*, edited by Erasmus Wilson, F.R.S., and which is to appear quarterly. The editor has secured the services of Dermatologists in England, Scotland, and Ireland, all three kingdoms being represented in the present number. He presents a very bold front to the opponents of specialism, and defends not only special journals but special hospitals, with a vigour and pungency quite agreeable. We shall not be expected to analyse the twelve original contributions in this brief notice. They are such that if names command success the new Quarterly may be considered as already established. The journal is 8vo, and the printing and getting up altogether unusually excellent. The other candidate for favour is *The Laboratory*, a weekly of the size of *Notes and Queries*, and which will be devoted to chemical and physical science. We are very much pleased with the first number, which contains several good communications. In the editorial department a first-class protest is made against the too common assumption of titular letters calculated to mislead as to their meaning. We are glad to welcome this organ of opinion and record of scientific progress.

#### CHOLERA REPORTS.

We are requested to state that it was the intention of Dr. Lyons to substitute for the section on treatment in the report of the Hardwicke Hospital, a more matured general statement of the nature and results of the various plans of treatment employed in the last epidemic, but the short period at our disposal for the publication of these abstracts compelled us to print off the abstracts as they stood. In a future number we hope to give a revised summary of the treatment employed.

#### LUNAR CAUSTIC SUPERSEDED BY SOLAR CAUSTIC.—

For a long time, in the treatment of places to be cauterized, only the dreaded nitrate of silver (lunar caustic) was used to produce the caustic effect. We now use several substances, but Barnes substitutes for all these the sun's rays converged by a burning lens, in all cases (cancer, &c.) in which caustic has been used, and the morbid character of which has to be extinguished. This solar burning is far less painful, non-injurious, and far more effectual than escharotic substances, or even hot iron.—*New York Times*.

### GREENWICH HOSPITAL.

FROM what has transpired during the week, it would seem that the Seamen's Hospital Society is in danger of losing the advantages for which the promise of the Prime Minister was deemed a sufficient guarantee. When the managers of the Society—their cause having been advocated by most of the organs of public opinion—were informed that “Her Majesty's Government were perfectly willing to grant the loan of a part of Greenwich Hospital,” they naturally concluded that the merchant seamen, who have hitherto depended for Hospital relief on the *Dreadnought*, would henceforth be accommodated in a building particularly well adapted for this purpose. It seems, however, that a *hitch* has occurred, and that, after all, they have been “reckoning on their chickens” too early. The Admiralty, in fact, now offer a portion of the building which is utterly unsuitable for the purpose, and which the Society will, therefore, be driven to decline. That there is no need for such a step as this is abundantly evident from the fact that there now remains almost untenanted a part of the edifice which, at a moderate expense, would be exactly fit for the proposed purpose. Whence, then, this perversity on the part of the Admiralty? It has been boldly asserted that the part most suitable for hospital purposes is refused because it forms the most pleasant apartments for officers. The conveniences of these *officers and gentlemen* is, no doubt, a very important matter to them; but we scarcely imagine that Parliament will consider it so paramount as to sanction the claims of the sick seamen being put on one side. Nor do we believe that the Government will, in the end, be persuaded to prostitute a noble national edifice to the personal comfort of a few men, however great they may consider their claims. There are many ways in which the country may express its gratitude to officers who have rendered essential services, and the English people will not be slow to recognise such

claims. It is, therefore, necessary to impress on those concerned that we have only one Greenwich Hospital, and to that the sailors of the mercantile marine have long contributed a proportion of their wages. This matter may, therefore, be looked upon in the light of strict justice. On behalf of the sailors, the Society asks for what is already partly their property, and this claim has been allowed by the House of Commons. Were it a mere matter of generosity, it were well to give handsomely, if at all, but in a case like this a mean subterfuge is simply intolerable. The quarter desired by the *Dreadnought* authorities is exactly suited to their wants in size, as well as other particulars; it is less connected with the other parts of the building; it is farthest from the schools; it possesses a river frontage which would make it accessible from a boat, a very great consideration; it has neither pensioners nor “helpless” wards; it is divided by numerous wooden partitions which could easily be removed, and thus large, airy wards be made at a trifling expense. In all these particulars the part offered by the Admiralty affords a remarkable contrast, and unless the authorities yield to the pressure of public opinion, the Society must decline their proffered accommodation, and proceed, at a vast expense, to erect side by side with the vacant hospital a building very similar. Why should needless waste be incurred? If only to gratify a few retired officers it will be one of the greatest *jobs* ever perpetrated.

What does the Admiralty propose to do with their possession? simply nothing, but expend a few thousands a-year on keeping it in repair. Were they to come forward with a scheme to create a great Naval Medical School like that of the Army Department, and offer to admit into the Hospital the merchant sailor as well as the seamen of Her Majesty's Navy, we could understand their desire to retain control over the building. Even then there would be no great difficulty in reconciling the conflicting claims by granting the Seamen's Hospital Society a wing in which to carry on their operations in conjunction with the staff of the Naval Hospital. Such a scheme, would, we believe meet with the approval of the country, and we throw out the hint for the benefit of all whom it concerns. If thought desirable, it would be by no means difficult to submit the whole Hospital to one Board of management. The medical men who have most distinguished themselves by their connection with the *Dreadnought* could receive appointments of some kind in the National Hospital, and would be found worthy and acceptable colleagues of those Naval Surgeons who would be their colleagues. The other parties interested only desire the welfare of the sick sailor, and would therefore, no doubt, be delighted to cooperate. What, then, is there to hinder the realization of the scheme we have sketched? A magnifi-

cent hospital is already built; there is a princely income already set apart for the seaman. Why should not England possess a Naval Medical School worthy of her position as the greatest sea-faring country in the world? To be sure our proposal would necessitate the inauguration of an era of justice to the Naval Medical Service, and is therefore likely to meet with hostility from some of the Admiralty authorities. But the grievances which have so long banished the best men from the Navy cannot continue much longer. The Admiralty must mete out justice to their Medical Officers. Bit by bit all that has been demanded will be given. Year by year the voice of the Profession will make itself heard in Parliament until the wrongs so long endured have all been redressed, and the Navy presents a sphere of honour which will attract a full supply of candidates anxious to place the highest surgical talent at their country's disposal. Why not at once inaugurate a better system? Why lavish millions on every kind of armament, and yet perpetuate a system which, in the event of a sudden outbreak of war, would leave our wounded sailors unprovided with a sufficient surgical staff to cope with the emergency?

---

#### THE OBSTETRICAL SOCIETY AND MR. BAKER BROWN.

AFTER a week's review of the proceedings in this *cause celebre*, we see no reason for changing our first opinion—that the entire affair will long be a subject for regret to all sections of the Profession. It appears to us that even the mode of proceeding was objectionable. The condemnation of Mr. BROWN should have been the general and spontaneous emanation of the Society, and the charges should have been referred to a Committee for investigation. It is alleged, indeed, that Mr. BROWN did not at the last moment afford the requisite facilities for such a course of action. But it was not for Mr. BROWN's satisfaction that a Committee should have been appointed, but for the satisfaction of the Fellows of the Obstetrical Society. The steps actually adopted have been as diverse from this, or any other form of justice, as can well be imagined, and remind one of nothing else so strongly as the tactics of the defunct Jamaica Committee, or any other similar overflow of party political spirit, and we fear will tend to degrade the Obstetrical Society from its scientific position, and reduce it to a mere Club, where Medical coteries strive for mere personal ends.

For ourselves, we shall never cease to regret that the Council adopted such measures as they did. Whether Mr. BROWN is unfit for Medical society or merely indiscreet, it is not surprising that he failed to stand against such an overwhelming attack. The Executive of a Society, having full power over the

apparatus and machinery, may well overpower the resources of a private member, if he be not exceedingly popular and influential.

We regret, also, that it was necessary to make such an earnest appeal to the Fellows, for surely all those present knew as well as the Council the nature of Medical ethics, and were sufficiently interested in the well-being of their Profession, to vindicate its morality without such extraordinary stimulus.

If the course which we advocated had been adopted, it is by no means certain that the result would have been the same. A vote of the Fellows for the expulsion of a member on a charge of Medical immorality ought to be all but unanimous. Notwithstanding all the pressure, only half the Fellows attended, and of these forty-one voted for Mr. BROWN. We can understand such a painful variation of opinion as that manifested by the vote on a difficult scientific subject, but such a variation on fundamental medical morality, especially under the influence of the lecturing and drilling and chastening to which the Fellows were subjected by the Council, is proof of dissensions which may yet prove the ruin of the Society. On the one hand, the Executive, with a machinery always ready to be set in motion, occupy months in private and rigid enquiry into the moral conduct of one of their Fellows, they whip up their rural supporters, they threaten to resign to a man if their point is not carried. Yet after all this violence and frenzy, what have they to show? a majority of thirty-eight above the two-thirds required by the bye-laws, one-half of the Fellows only being present. We can understand the wisdom of acting on a much smaller majority on the primary election of a Fellow, but the expulsion of one on such charges, in such a manner, must, we venture to think, when the bitterness of party spirit has passed away, be looked back upon as an episode calculated to prove most injurious to the prosperity of this Society.

---

#### THE REFORM OF THE SANITARY LAWS.

THE Memorial presented by the Social Science Association to the Government through the Lord President of the Council, and reprinted in our columns last week, referred to a condition of the law as injuriously anomalous as any the statute-book contains. The earnest representations of the influential deputation which took the matter in hand cannot have failed to impress the Lord President with the fact that the laws as they stand at present are regarded by practical men as all but useless and that their amendment is urgently demanded, and that the matter is of sufficient import to require attention from Government at the earliest period after they are extricated from the Reform block which now stops the legislative traffic.

Nothing can be more eloquent of the muddle which exists in the public and the official mind on matters in connexion with sanitary legislation than some of the facts mentioned by the deputation. It appears that the administration of sanitary matters is at present a divided responsibility with four separate departments—the Privy Council, the Police, the Guardians, and the Registrar-General, and as each act is more or less dependant for its efficient working on the other, each department ought to work in harmony with the other.

It is not difficult to imagine that this condition of official concurrence is not fulfilled, and that the Privy Council know as little of the Guardians as the Police do of the Registrar-General. An amusing instance of this was quoted by one of the speakers. A certain Vestry Board in London initiated sanitary reforms under an Act of Parliament, and in the exercise of their powers they printed and circulated sundry regulations. Having obtained possession of one of these printed forms, and being desirous of following the example, another Vestry adopted the regulations, and sent a copy to the authorities for approval. In answer they received a sharp note informing them that the powers they sought were perfectly illegal, and could not be sanctioned. Manifestly the writer of this letter never heard of the Act of Parliament under which these powers were conveyed, and he was speedily extinguished by a note calling his attention to the existence of such a statute. Medical Officers of Health thus finding their action under one Act barred by another, and the abuses which they desire to remedy perpetuated by the protective influences of inefficacious laws, appeal to the Government for redress, and for a revision of the law which will make it efficient for the purposes for which it was framed. Their complaint that a system of legislation in which each Act is intimately connected with the other, so that proceedings under the powers of one must necessarily trench on the provisions of the other, is under the control of four different and unconnected authorities, is manifestly a common-sense objection. There ought to be one responsible authority, and in that authority ought to be vested all the experience and intelligence in sanitary matters which is now sparingly distributed amongst officials who, perhaps, hardly consider such trifles worthy of their consideration. In the nomination of this central sanitary authority the deputation were not prepared to offer any explicit suggestion. The hint of a cherished hope that a Board of Health might be established, with a responsible representative in Parliament, was allowed to escape, but it was judiciously not pressed, partly, we imagine, lest it might be considered as an implied slight to the very valuable sanitary function of the Privy Council, and its Medical Officer, Mr. SIMON, and principally lest so sweeping a reform might embarrass

the ready action of Government. We have more than once represented the great public need of some such central sanitary authority, and we venture to press the suggestion upon the Government with more ardour than the deputation assumed. But if there be any existing official source more suitable for the exercise of these functions, it is the Registration Department, which could with facility be expanded to meet the requirements, and already possesses a mechanism proved to be valuable for such purposes.

But the acceptance of this suggestion must fail of itself to remedy the existent evil, because the Acts are in one respect intrinsically inefficient. Most of these measures unfortunately depend for their working on the progressive tendencies of Boards of Guardians and Vestrymen, to whom the power is given of acting or not, just as they think fit. They may appoint Officers of Health and Inspectors of Nuisances, and may provide carriages for the accommodation of patients labouring under infectious diseases, but experience shows that in nine cases out of ten these powers are grossly neglected, or even wilfully obstructed. Knowing the intellectual capacities of Boards of Guardians as we now do, the statistics of their obstructiveness are not surprising. It was stated by one speaker that only eighteen towns out of fifty-nine from which he had obtained returns had availed themselves of the permissory powers to provide carriages for infectious diseases—that the numerical proportion of the Health Officers to the population varied from 1 in 4000 persons up to 1 in 211,000, and their salaries from £12 a-year in Aberdeen to £1000 in Liverpool. The fact that, on an average, there is but one Health Officer to every 60,000 inhabitants, and 1 inspector of nuisances to 30,000, is sufficient to discredit the whole system, and ought to convince the Government that the administration of the Sanitary Laws has been placed in wrong hands. We can hardly hope for any prompt action in this matter, but we cannot doubt that the expression of interest volunteered by the Lord President was heart-felt, and that the Social Science Association may hope for a redemption of his promise to them.

#### THE PRIVILEGE OF MEDICAL CONFIDENCES.

THE arrest of Dr. Keogh, the medical officer of the Carrigaholt Dispensary District, for “knowingly comforting and concealing” Thomas Fennell, who stands charged with high treason as a Fenian, raises a medico-ethical question of no little difficulty. It appears that Dr. Keogh was sent for to attend a sick woman, and after his attendance on her was told that he was wanted by a sick boy in the next room. He found this boy suffering from the effects of a gunshot wound, and he did what was necessary for him without informing the authorities of the fact. It does not appear that Dr. Keogh knew anything about the wounded man when he went to attend the sick woman, nor had he any other reason to know that his patient was a Fenian,

except a natural suspicion from the nature of the wound. Assuming his knowledge that the man was a traitor, a very serious question arises as to the course the medical man ought to have pursued. We quote below the address of the defending Council, and the observations of the Magistrate in giving judgment:—

“Mr. O’Loughlen, in a most eloquent and argumentative speech, upheld the question of privilege to which he considered his client, as a medical man, eminently entitled. The learned gentleman adverted to the obligatory oath which was imposed on Dr. Keogh and on every duly qualified member of the medical profession—and which, as a physician and a man of honour, he was bound to observe. Then, it was a fact that Dr. Keogh was a stranger in the locality where he lately went to reside. The learned counsel held that even if he did visit the sick man, it was no part of Dr. Keogh’s duty to become a public informer. Had he done so, he would consider that Dr. Keogh would have forfeited the esteem and respect of the high and honourable profession to which he belonged. The learned counsel observed that the laws of the British constitution were also clear on the subject, which laid down, that every subject of the realm was presumed to be innocent of crime, until proved to be guilty by a jury of their countrymen. The accused Fennell formed no exception. After descending on the privileges to which Dr. Keogh was entitled, and to the law bearing on the subject, the Counsellor said he highly approved of the honourable and humane course pursued by his client.

“After a judgment from the magistrate acquitting Dr. Keogh, the Chairman said, I do not think I can add anything to the very clear and able analysis of the evidence in this case which my brother magistrate, Mr. M’Cullagh, has just pronounced, and I fully concur in the judgment arrived at, that there is not sufficient evidence to allow the case to go farther. I should have contented myself with this short expression of my opinion, were I not apprehensive that some expressions of my friend, Mr. O’Loughlen, should be taken as laying down the law with respect to the privileges of professional men, in reference to persons involved in the charge of high treason. Although medical men are sworn to keep the secrets of their patients, this is subject to the restriction that in cases of high treason those medical men come within the plain and clear law, that any person, whosoever, who shall knowingly help, comfort, assist, or shelter in any way, a traitor, is himself a traitor. This is, I believe, the universal rule of all nations, and I know it prevails in America, for there the medical man who set the leg of Booth, the assassin of President Lincoln, was tried and hanged as a traitor. There are no accessories in high treason, all are principals, and from the very necessity of the thing, counsel and attorney are protected by the law, and I hope they will always be protected, and not only protected, but if they should betray the secrets of their clients in the most remote degree, they would be held accountable for so infamous an act. But in the case of medical men or of clergymen of any persuasion, there is no protection whatever. Nay, further, in the case of clergymen, so emphatically and clearly is the law in their case laid down, that I find in 23 Henry VIII. c. 7, s. 3, *that there shall be no sanctuary for traitors.* Even the holy precincts of the Church was and is no safeguard for these persons.”

It appears to us that in this question of privilege more depends on the circumstances of the case than on the construction of the law. Whatever the law may be, we should all feel ourselves not only morally justified, but prompted by all the dictates of humanity to succour a man whom we might find, without our seeking for the occasion, seriously wounded, and we would consider it a cowardly and dishonourable act to make use of the unwilling confidence of such a patient to hand him over to justice. But we can

well understand that, going out of our way to assist traitors, and concealing a knowledge of their guilt, which is not a matter of suspicion, or forced upon us by circumstances, is, and ought to be, an offence against the law. Though we cannot, therefore, condemn the law which makes such a degree of “succouring, comforting, and concealing” a participation in the crime, we believe that the law never contemplated the enforcement of the penalty in cases like that of Dr. Keogh. We believe that this principle of honour would be more or less connected with the nature of the crime, and the same rule of conduct which applies in the case of a political offence, however abhorrent to a proper loyalty of feeling, will morally apply, with less force, to the case of a murderer. If this latitude were not allowed to the profession, the criminal has only to choose between the penalties of the law and the danger from his injury; and we do not think it could have been the intention of English law to drive him to the scaffold by withholding medical relief.

### Notes on Current Topics.

**THE PRINCESS OF WALES.**—It is universally regretted that the health of her Royal Highness continues to give cause for anxiety. Mr. Hawkins and Mr. Pollock have both seen the royal patient, in consultation with Mr. Prescott Hewitt and Mr. Paget. In deference to the well-known wishes of the illustrious family, we have all along abstained from comments on the case, except such as were really called for by the public interest excited on behalf of the Princess, who has endeared herself to the nation. We shall continue to maintain what we consider a judicious reticence, merely repeating that the information we have given has been absolutely correct, while the attempt of some of our contemporaries to give a different version to the facts, is as erroneous as it is uncalled for.

**HEALTH OF THE FRENCH IMPERIAL FAMILY.**—The illness under which the Prince Imperial has laboured, has not, we fear, taken a more favourable turn. There prevailed some time since an apprehension in Paris, that some serious disease of the femur, or even of the hip-joint, was the cause of the abscesses from which the Prince is known to have suffered. His inability to be present at the opening of the Exhibition tended to increase this anxiety. We are now informed that the Empress is indisposed, her health having been shaken by her anxiety and constant watching by her invalid child. Under the care of their distinguished attendants, both patients will receive all the alleviation that art can afford, and we hope both will shortly be restored to their usual health.

**THE LONDON COLLEGE OF PHYSICIANS.**—Who is to be the next President? That is the question just now occupying the Fellows. Much regret has been expressed that Sir Thomas Watson, who has been so thoroughly popular, should wish to decline the honour of again being re-elected. While, however, he may fairly expect to be relieved from the further performance of the arduous duties of the office, we doubt not either of the gentlemen who have been mentioned as likely to succeed will, if elected, prove equal to the position. Each of them may, naturally enough, hope to give general satisfaction, and, we trust, whoever may accept the honour may be able to maintain the reputation of the ancient college, if not increase its prestige.

**A NARROW ESCAPE.**—At the Spring Petty Sessions, last week, a woman named Harrison charged Mr. Saunders, surgeon, of Chigwell, with an attempt to commit a rape upon her in her own house. She declared she screamed, and that at length her servant came, but her husband, who was within hearing, did not. The story completely broke down in court—so completely in fact, that Mr. Sleigh, who had been retained, withdrew from the prosecution, and Mr. Saunders was declared by the Court to leave without a stain on his character. But had the prosecutrix engaged some unprincipled barrister, instead of so honourable a man as Mr. Sleigh, to how much extra expense and anxiety he might have been subjected?

**DR. RICHARDSON'S LECTURES.**—On the second instant Dr. Richardson, whose numerous contributions to science have made his name so familiar, and to whom a testimonial has been raised principally in consequence of his ingenious application of cold by the ether spray for producing anæsthesia, commenced a series of lectures on experimental and practical medicine, at his house in Hinde-street, Manchester Square. The first lecture was on a new styptic and adhesive fluid, which he calls styptic colloid, and on healing by the first intention. We listened to the lecture with the greatest pleasure, and can testify that it was well received by an unusually influential audience. It is quite a new thing in London to have lectures at private houses, but Dr. Richardson has proved that a man with something to communicate will find no difficulty in obtaining an assembly outside the walls of a hospital. He will continue the course on the first Tuesday in each month. We wish him the success he deserves, and advise those readers who may have the opportunity of attending to purchase tickets.

**STRANGE COINCIDENCES.**—Few people but have occasionally indulged themselves in some reverie or even neutral expressions respecting the curious coincidences that sometimes occur among the lesser events of every day life. The other day a gentleman remarked to us that he had never known more than three persons whose names commenced with a certain letter of the alphabet, and had never heard a person's name commencing with a certain syllable of three letters. The conversation over, he went to his consulting room, and, curiously enough, the first patient's name began with that very three-letter syllable, and the two next patients' names commenced with the same letter of the alphabet. Each reader will probably be able to parallel this from his own experiences.—In turning over the leaves of a recent number of this journal a rather strange coincidence struck us. In one column was an account of the proposal to eject Mr. B. Brown from the Obstetrical Society of London; in another an item of news in which that gentleman's name is also mentioned, being in fact a description of a testimonial of plate which has been subscribed for, and is now on view at Mr. Benson's, the jeweller, of Bond-street. The curiosity of the thing is, that neither contributor knew anything about the other contribution; so that each, on reading his copy of the journal, could learn from it something in odd contrast with his own information. We should add, that the same week the two same facts were brought prominently into notice by a considerable number of newspapers.—Another very singular fact respecting the same affair is that on the 15th March, the reader of the *Times* who glanced over the advertisements might have been astonished by his eye lighting

upon the following in the second column of that journal, where are always placed certain, private and strange, announcements, and which is, from the character of its contents, sometimes sportingly called the "agony column":—

"The London Surgical Home.—The porter (called Brown) who was engaged at the above institution in September last, is requested to make an early appointment with Mr. W. Talley, Solicitor, 13, Piccadilly, W., on business of public importance."

Such a method of waging war as this is not likely to add to the dignity of gentlemen belonging to a society for promoting science, nor to the respect with which their decisions on points of ethics will be regarded.

**THE REGISTER OF MEDICAL STUDENTS.**—The official list of students registered during the year 1866 has just been issued by the Medical Council. It gives in parallel columns the name of the student, date of registration, certificate of preliminary examination, and place of study. We have taken the trouble to prepare an analysis of the last column, but we publish it rather as an evidence of the inaccuracy of the returns and the inefficiency of the registration system, so far as it has gone, than as affording any reliable information. The extraordinary disproportion in the numbers attending different schools indicates some fault in the machinery by which these registrations are effected. The following are the returns:—

Number of Students attending in the Medical School of the United Kingdom.

#### LONDON.

Guy's Hospital, 85; University College, 54; St. Bartholomew's Hospital, 47; St. Mary's Hospital, 41; St. Thomas's Hospital, 29; King's College, 28; St. George's Hospital, 21; Charing-cross Hospital, 7; Middlesex Hospital, 6; Westminster Hospital, 4; London Hospital, 3.

#### PROVINCIAL.

Birmingham, 22; Manchester, 21; Cambridge, 17; Liverpool, 15; Bristol, 14; Newcastle, 13; Leeds, 12; Hull, 6; Oxford, 3; Sheffield, 2. All others, 21.

#### IRELAND.

Ledwich School, 38; Royal College of Surgeons, 25; Queen's College, Cork, 24; Carmichael School, 21; Queen's College, Galway, 18; Catholic University, 11; Trinity College, 8; Stevens' Hospital, 7.

#### SCOTLAND.

University of Glasgow, 110; University of Edinburgh, 75; University of Aberdeen, 52; Anderson's University, Glasgow, 27; Royal College of Surgeons, Edinburgh, 13; Surgeon's Hall, Edinburgh, 1.

Total number of students registered, 901.

## SURGICAL SOCIETY OF IRELAND.

The President of the College of Surgeons, Dr. BUTCHER, in the Chair.

**LATERAL OPERATION OF LITHOTOMY FOR THE REMOVAL OF A CALCULUS FROM A PATIENT WHO HAD BEEN SUBJECTED TO LITHOTRITY BEFORE HE CAME TO DUBLIN.**

THE PRESIDENT MADE the following remarks on the operation of lithotomy:—

Gentlemen,—I thought it would be interesting to submit to your consideration the details of a remarkable case of calculus in the bladder, upon which I operated this morning in Mercer's Hospital, and making such remarks as I think applicable to the subject. The patient was a labourer, aged 65, and a sufferer from stone for over four

years; throughout the greater part of this time his sufferings were excessive. Four months ago the stone was detected by an able surgeon in the country, and lithotripsy performed upon him. A few fragments were broken off and expelled from the bladder; severe symptoms of irritation set in, and no further attempt made of breaking up the stone. A few weeks since he was sent from the country and placed under my care. The patient suffered most intensely after the journey. The day of his admission into the hospital, he was writhing in torture, ever trying to pass a few drops of water, and always an aggravation of suffering after the effort and the issue. The usual means for subduing inflammation and irritation of the bladder were had recourse to. The warm bath, hot stupes over the vesical region and perineum, the internal administration of sedatives and antispasmodics, together with wine and demulcents, and strong broths to sustain the wearied powers of life. I would wish to lay great stress upon the necessity of attending to position in cases similar to the present. The hips and loins of the man were raised upon pillows far higher than his chest and head, which lay on a horizontal plane, the object being to allow the stone to fall back from the irritated and most sensitive neck of the bladder, and so when the organ even was empty that its weight should be directed by gravity backwards. After some time the patient's sufferings were comparatively lessened, and by a perseverance in the adoption of those means which I have alluded to, with but little variation for some days, the urgency to make water and the rapid demands to do so were not so oppressive. From being up some ten or twelve times in the night, and nearly as often by day, as was the case on his first admission, tranquil rest at night for a couple of hours together was insured, and probably as long intervals of repose by day; nevertheless, the case was still a very extreme one, surrounded with difficulties and risk. On examination by the rectum, the prostate was discovered considerably enlarged, the lateral lobes, almost in equal proportion (the right half somewhat the larger), forming a large massive tumour. Seven days since, I sounded the man to make certain of the presence of the stone, of which none of the equivocal symptoms were absent. The greatest gentleness was adopted in the introduction of the sound, yet it was by no means an easy matter to make it lightly travel over a very rugged urethra. The size of the instrument employed was a medium one (No. 9) of the catheter scale. On the conveyance of the instrument into the bladder, extreme torture was experienced, as scarcely any water could be retained, either by the efforts of the patient or by artificial supply. The bladder would not distend, therefore the range of the sound was very limited. I then passed the index finger of the left hand into the rectum, and felt the bulging of the bladder backwards, and through the coats of it and those of the rectum readily felt the stone and lifted it up to the sound, striking upon it with a sharp audible click not to be mistaken, and recognisable some feet from the bed. Certain now as to the presence of the calculus, its locality, and the pathological state of the viscus itself, as well as that of the prostate and parts around, I at once removed the sound as quickly as I could, and with as much gentleness. I measured the stone and found it to be in one axis an inch and three quarters, and an inch in another. Considerable irritation was set up after this examination, and days of the most careful management were required to subdue it. In addressing an assembly of practical Surgeons such as I see around, it is not necessary to specify the means more minutely than I have adverted to as having been adopted on the reception of the patient into the hospital. I may add, however, so tardily did the excitement subside that I determined on not again sounding him. From the contracted condition of the bladder, the enlarged prostate, the enfeebled state of the man from repeated suffering, now that a time of repose was obtained I considered it most advisable to remove the stone by the lateral operation from the bladder, and so give the man a chance for his life. The patient being prepared for the operation, the rectum cleared

out by an enema last evening, and this morning by warm water; as no urine could be retained in the bladder, a small quantity of tepid water was thrown in, not more than a wineglassfull, as the bladder would not relax; and so he was brought into the operating theatre, placed under chloroform, the staff passed, bound hand and foot after the ordinary mode, and brought to the end of the table. The ordinary incisions were adopted, and the bladder rapidly reached with the knife, shaped as figured in my work on "Operative Surgery," the instrument being, of course, larger for the adult subject. I did not find it necessary to use the blunt-pointed knife. The index finger of the left hand passed along the staff lay within the neck of the bladder, and then the staff was withdrawn, and upon the finger the blunt gorget conducted to the bladder, and by the gorget the forceps. The gorget being taken away, search was made with the forceps for the stone, but the bladder was so contracted, and the prostate so large, that it could not at once be discovered. I quickly passed the index finger of my left hand up the rectum, and lifted the stone into the chops of the forceps, and commenced to extract. A good deal broke away from the stone, and it slipped loose, but by the same manœuvre I instantly caught it again and extracted a large piece fully the size of a hazel-nut—this being the nucleus, and pronounced by Dr. Haughton to be composed of oxalate of lime. I next with the forceps and scoop removed a large quantity of considerably-sized fragments and a good deal of detritus, and then washed out the bladder. I present to you the stone all crushed, together with the large nucleus, as it was removed. Besides the large quantity there, there is nearly as much more detritus drying on bibulous paper. The "canule à chemise" was next introduced, and fastened by tapes in its position—the man unbound and placed in bed, with his thighs tied together, and a pillow supporting his hams. There was not a tablespoonful of blood lost, and but a very few moments passed in executing the operation. I shall now dwell upon a few practical points in relation to this operation, and first as to the position of the man when brought to the end of the table. Before the knife is used, I would urge the necessity of having the soles of the feet to rest upon the table, by such position the accurate axis of the pelvis is insured, and one conversant with the anatomy of the region cannot err either in the application of the cutting-knife, or from the proper line of traction with the extracting forceps. Now, as to the staff, it was such as I have described in my work on "Operative Surgery," the side upon which the knife is lateralized, that is the right side of the staff, when introduced as presented, to the operator, should be a little lower in its edge than the opposite side; this arrangement allows the knife to be turned outwards sufficiently without lifting its point from the deep part of the groove of the staff, which might endanger its slipping; and it likewise preserves the sharp edge of the knife from injury in the effort to lateralize it when the staff is held, as it should be, perfectly straight and well up to the pubis. The staff should never be rested upon the stone, and, as it were, made a guide to it; no, the staff should be held, I say again, tight up to the pubis, and so it keeps the knife out of harm's way behind. When the bladder is fairly cut into, there is sufficient time to be solicitous about the stone. I mentioned I did not use the second knife in this instance; but when the wound in the prostate is to be enlarged, it is the most manageable and safe of all instruments; it is so narrow in its blade, and guarded at its end by the blunt point. Now, with regard to the formation of the end of this knife, I would wish to say a word: If, after the membranous portion of the urethra is laid open throughout, the surgeon wishes to complete the incision through the prostate with this knife run along the groove of the staff, it is essential the blunt end of the instrument should not be long; the one I employ is not more than the eighth of an inch, and for this reason: if the upper part of the blunt end of the instrument rises out of the groove in the staff, it is apt to hitch against the fibrous bands and structures, essential to be divided in its upward course to the bladder, which obstruction may tilt

the blade from the staff altogether, and facilitate its going in a wrong direction. I have mentioned that the more fragile portions of the stone were broken when grasped by the forceps; had I not been able to extract it through the small aperture which I made into the bladder, I was prepared with a lithotrite to break up the stone, rather than increase the opening in the diseased prostate and irritated structures around. Under similar circumstances, I would always recommend this practice, rather than use violence or the knife freely. The "canule à chemise" I use in all cases after the operation for lithotomy, both in the young and old, left in, according to circumstances, from eight and twenty to eight and forty hours, or even longer; it at once averts, by its support, any weeping from the track of the wound. When it is in it may be used most advantageously if intermediary hæmorrhage should set in after reaction is established; it at once secures a ready outlet for the urine coming into the bladder, it guards against any gluing-up or plugging of the channel from the bladder, which, under other circumstances, I have seen to occur, and it is all advantageous to the surgeon in those cases where his incisions may not have been as direct as they should be, in preventing extravasation. I may just conclude by saying I have seen the patient just before coming here to-night, and, in every circumstance, he is going on most favourably.

[Since going to press, Mr. Richardson has received the following letter from Mr. Butcher regarding the progress of his case of lithotomy:—

SIR,—In answer to your enquiry about the case of stone upon which I operated and made some observations at the meeting of the Surgical Society held on the 29th of March, I am happy to tell you the man is nearly well, the wound being almost healed. He is improved in the most remarkable way in appearance, and free from all suffering. It is now a little more than a fortnight since the operation.—My dear sir, yours faithfully,

RICHARD G. BUTCHER,

President of the Royal College of Surgeons.

April 12, 1867.

To B. Wills Richardson, Esq., F.R.C.S.I.,  
Hon. Sec. Surgical Society of Ireland.]

Mr. BANON, Vice-President of the College, made the following communication on a

#### REMARKABLE CASE OF OVARIOTOMY.

The subject of ovariotomy is one which, within the last ten years, has created much discussion among surgeons, and indeed it is only within a very recent period that, by the labours of Clay, Tyler Smith, Spencer Wells, Baker Brown, and several other distinguished men, principally English practitioners, that it has been raised to that important position in surgery it now occupies. The comparatively few instances in which it has been performed in this country, may render the case which I am about to bring before the Society of more than ordinary interest. Some few years ago the propriety of having recourse to this operation was considered by most surgeons as more than doubtful, but from the great success which has recently followed its adoption, in suitable cases, its recognition as an established operation is fast becoming generally acknowledged. It may still, however, fairly be questioned whether a proceeding which in itself must involve much danger to the patient's life, should be undertaken, no matter how favourable it may be for the operation, where the progress of the disease does not threaten life or cause much or serious suffering. In the case which I shall have the honour of detailing to the Society, we were delivered from this difficulty, as such were the severity of the symptoms and the prostration produced by them, that it was evident the operation alone afforded any hope of prolonging the patient's life, even for a few days. I shall now give the history of the case as taken by Mr. McMullen, one of the resident pupils of Jervis-street Hospital.

"Margaret N—, ætat 17, admitted into Jervis-street Hospital, January 4th, 1867, under the care of Mr. Banon, labouring under a large abdominal fluctuating tumour, from which she suffered great distress. The account given by her mother was the following:—In February, 1866, she was led astray by a young man, and five weeks subse-

quently, when going to work at Chapelizod Mills, near which she resided, she fell, and her left inguinal region was bruised from coming in contact with a stone. She returned home and complained of deep-seated pain in that situation. However, no inconvenience resulted until the middle of the following June, when she observed that the abdomen was becoming enlarged, and continued to do so until last December, when she consulted Dr. Maguire, who recommended her to the hospital. The catamenia continued regular until the month of November, when they ceased, and have not since reappeared. The abdomen was much distended with fluid, emitting a dull sound on percussion in all its parts, and large distended veins were observed ramifying over its surface. Between the pubis and umbilicus fluctuation was not evident, the tumour here presenting a more solid character, and much resembling the gravid uterus of about the fifth or sixth month.

"A consultation was now summoned, at which several of Mr. Banon's colleagues attended, and also Dr. Beatty, who made a most minute examination of the tumour generally, and also of the uterus through the vagina. Some doubt existing as to the nature of the lower solid portion of the tumour, it was agreed to tap at the upper portion of the swelling, by which eighteen quarts of a fluid of a dirty brown colour was removed, containing an enormous quantity of albumen. This was done on the 15th of January. The measurements of the abdomen previous to the operation being fifty inches round the waist, fifty-four round the largest part of the swelling, and twelve from the ensiform cartilage to the pubis. Considerable amount of solid matter remained in the region of the uterus after the tapping, but Dr. Beatty satisfied himself by a careful vaginal examination, assisted by Mr. Banon's colleagues, and by Dr. Kidd, who passed the uterine sound, that it was unconnected with the uterus, and, finally, the diagnosis of ovarian tumour was made, and an operation for its removal decided upon when the patient's strength, which was much weakened, would warrant it. The fluid, however, again so rapidly collected, and the debility of the patient, her pulse being very weak, and varying from 116 to 120 beats in the minute, becoming so much aggravated, that Mr. Banon was again obliged to tap in one month exactly from the first tapping, to save the patient from impending death, from the effects of the pressure of the fluid on the diaphragm. On this occasion nineteen and a half quarts of fluid of a lighter colour, but loaded with albumen, were drawn off with much relief, the measurements of the swelling being still greater than when previously taken. It was now agreed to continue every possible means to bring up the patient's strength, and to take advantage of the first favourable opportunity to operate, but in one fortnight after the last tapping on Thursday night, the 7th of March, at half-past eleven o'clock p.m., Mr. Banon was sent for, and found the patient in such distress that he was obliged to tap her for the third time, and drew off nineteen quarts of fluid. It was now so evident that the patient's life could not be prolonged many days, unless an operation were performed, the 18th of March was fixed in order to give time for the cyst to fill to a certain extent. On the day previous, however, the patient was so weak, the pulse being scarcely perceptible, that the idea of operating on the following day was abandoned. She rallied somewhat during the next two days, and the operation was finally undertaken on last Saturday, the 23rd. The condition of this poor girl previous to the operation was very unpromising. Her pulse was very weak, compressible, and 120 in frequency. The fluid was again beginning to cause much distress, preventing her from lying down with any comfort, the stomach also frequently rejecting her food. The measurements immediately before the operation were, as taken by Dr. Walsh—largest girth at umbilicus forty-six inches, from ensiform cartilage to symphysis twenty-three and three-quarters, and umbilicus to pubes eleven and a-half. The operation was commenced, the room having been heated to a proper temperature, and all the preliminary arrangements made, as recommended by Dr. Spencer Wells. Mr. Banon being assisted by his colleagues, Dr

J. S. Hughes, Forrest, M'Swiney, Tyrrell, M'Donnell, and Martin, and by his friends Drs. Beatty, Gordon, Walsh, Hargrave, Kidd, and Geoghegan. Chloroform having been administered by Dr. M'Swiney, an incision five inches long, extending from below the umbilicus to within an inch of the symphysis pubis was made through the skin, and the subjacent tissues carefully divided on a broad director until the peritoneum was fully exposed. This membrane was then raised with a small double hook at the lower end of the wound, and slit up on the director for the whole of its extent. The cyst then came into view, and on passing the director between it and the parietal peritoneum it was at once felt to be extensively adherent to the latter membrane. The cyst was now tapped with Spencer Well's large trochar, and at first but little fluid escaped, but on pressing the trochar backwards and upwards it entered the large cyst, and between fifteen and sixteen quarts of fluid rapidly escaped. Mr. Banon now passed his right hand freely into the abdomen, and endeavoured gradually to break through the very strong and extensive adhesions to the front wall, and both sides of the tumour. In this he succeeded with difficulty, being obliged to use considerable force. It was found, however, that the tumour was still firmly adherent above and behind, and to render it more manageable it was again tapped in two or three different places, and about two quarts more of fluid obtained exit. He now endeavoured to draw out the tumour after separating firm adhesions at its upper part in close connection with the suspensory ligament of the liver, and behind to the stomach and colon, but found the solid matter was of too great a size to pass out of the opening. He therefore enlarged the incision to the extent of an inch and a-half at its upper part. The whole tumour now passed completely through the wound with the greater part of the great omentum closely attached, after separating which the pedicle was treated in the following way and the whole tumour removed:—

"The pedicle was found to be very short and broad, and on raising and looking through it, was found to contain several very large arteries and veins. Under these circumstances it was considered that the ordinary clamp would cause too much tension from the shortness of the pedicle, which, it should have been mentioned, was attached close to the uterus on the left side, and, fearing to trust entirely to the actual cautery from the number and size of its vessels, Mr. Banon passed a double ligature of hemp-twine through its centre, taking care, with the aid of good light, to avoid transfixing a vessel with the point of the needle, and tied one on each side as firmly as possible. The pedicle was then cut through and the tumour removed. Not the slightest oozing of blood appearing, the ligatures were cut short, and the pedicle stump allowed to drop in to the pelvis. On examining the interior of the abdominal cavity, Mr. Banon found there was rather considerable oozing of blood from several points on the front wall of the abdomen in the site of the adhesions. These were carefully seared with the hot iron with complete success, and it being now found that bleeding was taking place from the torn omentum, it was ligatured in two places with silver wire, the ends being carefully turned in, and the omentum beyond the ligatures divided, and removed by the hot iron. All clots and fluid were now carefully sponged out from the abdomen and pelvis, and the right ovary examined and found healthy, and no bleeding point being anywhere observed, the wound was closed in the usual manner by three deep silk sutures passing through the peritoneum, and between them superficial sutures of silver wire. Broad straps of adhesive plaster were applied, and over them French wadding and flannel, and the patient carried to a well-warmed bed.

"The patient bore the operation remarkably well, considering her very weak and almost collapsed state previous to it. Mr. Banon stated that he owed much to the assistance afforded to him by his colleagues, and Drs. Beatty and Walsh during the operation, and for Dr. Beatty's invaluable assistance and advice before, during, and subsequent to the operation, he expressed himself grateful. On

the patient being settled in bed, and the effects of chloroform had passed away, it having been admirably and effectually administered, her general condition could not be regarded as much more depressed than it had been previous to the operation; respiration tranquil; pulse 138, weak, but quite perceptible. An enema, containing brandy and beef-tea, was administered, and india-rubber heaters applied. An hour after the operation she had rallied so far that the pulse came down to 130. The catheter was passed, and six ounces of urine withdrawn, which was about the same amount taken away before the operation. No albumen at any time existed in the urine.

"At four p.m. the pulse had come down to 120, and was of a better volume. She now complained of some pain, and an enema, containing twenty minims of tincture of opium, directed; the bowels had been previously moved; brandy and beef-tea injections directed every four hours, and iced soda-water and milk by the mouth.

"Half-past nine p.m.—The patient continued in much the same condition, the bowels having acted several times. Another enema containing twenty-five minims of tincture of opium was administered. During the night she had some hiccough and nausea, which was relieved by ice; no vomiting. The brandy and beef-tea injections were continued, and the urine drawn off at intervals of five hours.

"Sunday, 24th.—This morning the pulse 120, weak; had slept for short intervals; complained of hacking cough and wheezing in the trachea, and of slight pain in neighbourhood of incision; no vomiting. Treatment to be continued. To have the following mixture:—

℞ Mucilaginis.  
Syrupi similicis aa. ℥iv.  
Liquor hydrochlor. morphiae ℥i.  
Aquæ ℥i.

M. cap. coch. med. urgente tussi.

"Monday morning, 25th.—Pulse 134, weak; cough quite gone; enemmas well retained; urine abundant; pain somewhat increased. Opium by injection as before. Tock nothing by the mouth but milk and soda-water, iced, and a little chicken-broth, which latter the stomach rejected twice when administered. Cannot be induced to take any stimulant by the mouth. Deep sutures removed.

"Tuesday morning, the 26th.—The patient now suffers distress from tympanites and increase of pain; pulse during the night varied from 120 to 128; countenance expressive of suffering. Ordered one grain of opium by the mouth every second hour. To have spongio-piline wrung out of hot water, and sprinkled with turpentine, applied over the abdomen, and renewed every second hour, and a drachm of mercurial ointment rubbed into each groin, to be repeated in four hours. An enema containing one pint of water, with half an ounce of turpentine, beaten up with yolk of egg, injected with long tube, and to be repeated in the evening if necessary. Injection brought away a number of scybala and some flatus with much relief. During this day she vomited three or four times, and the tympanites continuing, another terebinthinate injection was administered with some relief. In the evening two drachms of mercurial ointment, at Dr. Beatty's suggestion, were again rubbed in. Brandy and beef-tea injections continued, and also spongio-piline stupes. Pulse 120, stronger. Having taken four grains of opium during the day, the interval to be increased to three hours during the night, and the pills to be omitted should symptoms of narcotism come on. Has taken a little port wine; iced soda-water and milk agrees best with the stomach; chicken-broth again came off when tried; beef-tea and brandy continued by the rectum in two-ounce enemmas every second hour.

"Wednesday morning, the 27th.—Slept a good deal during the night. Tympanites still troublesome. But slight tenderness on pressure has been at any time felt in any part of the abdomen, though sore to the touch. This day the superficial sutures were removed. The deeper portions of the incision appear to be healed, but the skin not so. Scarcely any discharge is observed. Pulse 124, stronger. Mercurial ointment again to be rubbed in, and half an ounce of turpentine in half a pint of water injected.

"At six P.M. a large blister was applied below the epigastrium, where the tympanites is greatest, and directed to be dressed with mercurial ointment. Some port wine was taken through the day, and a little chicken-broth in the evening, which remained on the stomach; pulse keeping up, 120.

"Thursday morning, March 28th: Got a good deal of sleep during the night, and appears on the whole improved; pulse 120, stronger. Vomited once, but slightly, during the night, and then only the chicken-broth; opium directed to be continued, one grain every third hour; tympanites somewhat less; terebinthinate enema to be given in course of the day, and mercurial ointment to be again rubbed in; slight tenderness on pressure still present over abdomen; spongio-piline stupes still to be continued. She this morning craved for a little chicken, which was given and well retained, as well as some port wine; did not vomit during the day; pulse came down to 116; general aspect much improved; is more cheerful, and bore moving from one bed to another well; had a second bit of chicken in the evening, which agreed with her well; much inclined to sleep; opium to be omitted unless wakeful during the night.

"This morning, March 29th, seventh day after the operation, slept well during the night; effects of opium now passed off; to be resumed every third hour as before; injection of turpentine and assafetida administered, bringing away scybala and flatus with relief; has taken wine and iced soda-water and milk, and now asks for an egg and some tea, which has been given; no vomiting; pulse 120, stronger; ordered to continue beef-tea and brandy by the rectum, and stupes as before; back becoming slightly sore from pressure; sacrum to be protected with soap-plaster; was again changed to another bed with great comfort. No mercurial fœtor or soreness of gums produced by the mercurial ointment.

"At six o'clock this evening she was seen by Dr. Beatty and Mr. Banon. Her general aspect much improved; her voice, which was all through weak and indistinct, has greatly recovered its tone, and she is more cheerful and hopeful; pulse 120; had been earlier in the day as low as 116; still slight tenderness on pressure; retains fluid better; egg, chicken, and tea agreed with her well. Dr. Beatty saw the patient morning and evening regularly since the operation with Mr. Banon, and agrees with him in thinking that her present condition is much more favourable than could have been hoped for under the circumstances."

The details of this case I have given from the notes of Mr. M'Mullen, one of our resident pupils, who, with Mr. Kelly, alternately sat up with this poor girl every night since the performance of the operation, and both these gentlemen rivalled each other in the attention they paid her. Both Dr. Beatty and myself now entertain some hopes of her recovery. To this gentleman I am not alone indebted for his devotion and kindness, with which most of us are familiar, when we have the good fortune to come in contact with him, but also for the extraordinary amount of talent and acumen evinced by him in mainly assisting us to form a correct diagnosis in this very obscure and remarkable case. Before concluding my remarks, I may state that perhaps the most remarkable circumstance observed in this case was the extraordinary rapidity with which the fluid was secreted and the sac refilled after each tapping. In the numerous cases I have read of, described by Spencer Wells and others, I have not yet met one in which the fluid was poured out so rapidly. In the short period after the last tapping of one fortnight it will be recollected that between seventeen and eighteen quarts of fluid had collected. The great vascularity of the cyst may, in some degree, account for it. It may, perhaps, be said that an earlier operation should have been had recourse to, but it must be recollected that the diagnosis was extremely difficult, and a correct one only arrived at by the most patient and careful examinations, and then the extreme weakness of the patient would induce many surgeons not alone to pause, as we did, but to abandon all ideas of an operative proceeding. It was finally undertaken to give her her only chance, it being the

opinion of all who saw her that a few days more of such suffering as she was undergoing would, inevitably, terminate her existence.

Her present condition, though much more favourable than we could have hoped for under the circumstances, must be regarded with much uneasiness as to the final result, which I shall not fail to communicate at a later period.—At present all that can be said of the operation is that it has already probably prolonged her life, which was in immediate danger previous to its being undertaken, and it has most certainly relieved her in no small degree from the intense and intolerable sufferings she was undergoing.

On examining the sac, which was carefully done by Drs. R. McDonnell and Barker, it was found to be exceedingly vascular. It formed the bulk of the mass, and through one portion, which must have been close to the falciform ligament of liver to which it was attached, an artery as large as the radial at the wrist was found divided, and the veins ramifying over the different parts of the tumour were enormous. The base of the tumour, near the pedicle, was composed of many minor cysts, most of them containing clear straw-coloured fluid; a good deal of solid matter existed at this portion of the tumour composed of fibrous tissue. In two of the cysts flocculent shreds of fibrine were found, and in one a considerable quantity of cheesy matter remained.

Dr. Barker, who kindly examined the interior of the cyst, which Dr. R. McDonnell had not an opportunity of doing, states that on examining the internal surface and solid portions of the cyst, he found (corresponding to the anterior wall of the cyst) two fungous growths, about six inches from each other, of the size of a large walnut, attached by a broad base. They were soft and friable, and presented somewhat of a malignant aspect; their roots, too, were a little vascular. A microscopic examination with a quarter-inch object glass indicated cells of an epithelial character. Several very fleshy masses were also found in several parts of the cyst, from which exuded (when cut into) different kinds of matter—pus from some, a clear gelatinous fluid from others, and from one or two a clear matter resembling colloid.

These appearances are, no doubt, suspicious, and calculated to give us uneasiness as to their being of a cancerous nature, which time only can remove. The patient is young, and previous to the occurrence of this disease, enjoyed uninterrupted good health. Let us hope, then, that, should she survive the operation, her former robust health may be restored to her.

Dr. BEATTY wished to supplement this very important and carefully reported case by a few observations. In the first place he would say, as far as the operation itself went, that he never saw an operation performed more perfectly and more satisfactorily than this one. It would strike any one who witnessed the case that instead of being Mr. Banon's first operation it was his fiftieth; and if this woman recovered—for her life was still very much in the balance—it would be owing to the great attention which Mr. Banon had paid to the after-treatment—a subject on which the President had expressed a strong opinion in his comments on ovariectomy. Mr. Banon had described this case as a most unfavourable one, as a case in which the chances of recovery were very slight; and it might be asked "why, then, should he undertake an operation on an individual so close on the brink of the grave as this woman appeared to be?" He (Dr. Beatty) had brought with him the last volume of the "Proceedings of the Obstetrical Society of London," in which a very important passage occurred relative to a discussion on ovariectomy that took place in the last session of the Society. It was a portion of the observations of Mr. Spencer Wells. "Success in ovariectomy," said Mr. Wells, "did not depend upon any professional routine in any one step of the operation, but upon all the steps in the operation being well done by experienced men in properly selected cases. By this he did not mean that unfavourable cases were to be rejected. Far from it. If a patient were dying, and there was any reasonable prospect of saving her, and she was willing to run

a great risk, it became a duty to try to save her life. Only that day he operated upon a patient in the last stage of hectic fever, from a suppurating cyst, with a pulse of 140, and with scarcely a hope of success, because there was just a chance with the operation and none whatever without it. But to say there should be no selection of cases, and that the surgeon should do ovariectomy upon every patient with ovarian disease who came before him, was simply idiotic. As reasonable beings, we must refuse to do a serious operation where the disease, on the one hand, is one that does not threaten life, and, on the other, where it is of such a nature, that operation would be almost necessarily fatal." Acting on the principle there laid down, he counselled Mr. Banon to perform the operation. We considered the woman was dying rapidly. She was most desirous of relief, and, as far as the case had gone, Mr. Banon had every reason to congratulate himself on having undertaken the operation; for, before this time, if the operation had not been performed, the woman would most probably have been dead. As to some of the steps of the operation, he would say a few words. Mr. Banon alluded to the manner in which the pedicle was treated; and he (Dr. Beatty) was happy to say that the proceeding of expanding the pedicle, looking through it, endeavouring to discover the transparent parts of it, was first adopted in this country in the first operation which the President performed in Mercer's Hospital. There was no allusion to such a proceeding in any of the cases recorded by the eminent operators who had previously written on the subject; and it was due to Dublin, and to the President, to say that it was here that proceeding was first adopted to ascertain the proper place where the needle could be passed through the pedicle with safety. For it was notorious that a needle passed through a pedicle at haphazard, without care having been taken to avoid the blood-vessels, had sometimes caused an unfavourable result, from the circumstance of some of the blood-vessels becoming transfixed by the needle, and the delay and bleeding which resulted, causing the death of the patient. This operation was most successfully performed by Mr. Banon. The after-treatment, as he had detailed it, was founded on the common principles of surgery. It was quite plain that peritonitis, not of an acute, but of a low kind, had attacked the patient; and the medical treatment mentioned by Mr. Banon had been adopted so far with success. The peritonitis was met by the throwing up of turpentine, which not only assisted in the expulsion of fluids, but by its very existence in the intestines was a stimulant in itself—one of the most healthy stimulants that could be introduced into the mucous membrane of the bowels under the circumstances. The woman's life was in the balance. She had now passed through her seventh day, and he was inclined to believe she would recover. Her countenance was cheerful, her eye bright, and she was able to take solid food. He need not tell them that a woman with a pulse at 120 and the bowels still tympanitic was in a precarious position, but it was possible that her life would be spared, and if so she would owe her recovery to the skill with which the operation had been performed, and the extreme attention paid to the after-treatment of the case.

The Rev. Dr. HAUGHTON asked whether Dr. Banon considered that the tumour had a traumatic origin.

PROFESSOR HARGRAVE said he had witnessed this operation with very great interest and attention. There was great difficulty experienced in forcing the adhesions, but that difficulty had been overcome by Mr. Banon. After the tumour was cleared away, Dr. Banon examined into the condition of the right ovary, and it was declared by him and Dr. Beatty to be perfectly healthy. He thought these ovarian tumours must be considered almost as foreign bodies, and the sooner they were removed the better, instead of leaving them to increase and destroy the patient. By removing these tumours early they incurred less risk of inducing peritoneal inflammation, than if they waited until the tumour had attained a larger size. There was another point to which he wished to advert. He was happy to find that Irish surgery was returning to its birth-

right. These operations had now been performed in Dublin in the most skilful manner, and the treatment which had been adopted in the case just brought before the Society was in accordance with physiological and pathological principles. Contrasting this operation with that for strangulated hernia, he would call attention to the fact of how frequently they had patient's suffering from peritoneal inflammation in the latter, and the rule was death. Here it was remarkable that there was but little peritoneal inflammation, although the abdomen was laid open, the bowels examined, and the actual cautery used.

Mr. TUFNELL observed, with reference to strangulated hernia, that very frequently the peritonitis was set up before the operation, where the operation for strangulated hernia was performed early, death was not so frequent as when it was deferred to a later stage.

Professor HARGRAVE, in concurring in this view, said that when about to tie the common iliac artery, which he did for aneurism last session, a gentleman said, why not go direct to the vessel and disregard the peritoneum as ovariectomists do?

Dr. JOHN BARKER—With respect to the pedicle in these cases, he had examined some ten or a dozen of them, and he found that they consisted nearly entirely of blood-vessels, the arteries being very much smaller than the veins, which were very large. He had found great difficulty in perfecting a good injection of the ovarian cyst, in consequence of the extravasation occurring in the inside, the support of the fluid having been removed.

Dr. GEOGHEGAN said there was one point on which it was desirable to have the opinion of practical ovariectomists—namely, whether the peritoneal inflammation, which resulted in some cases, was due to the cutting short the pedicle and allowing the ligature to remain in the abdomen?

Dr. McDONNELL said a lady, a relative of his own, had an ovarian tumour five years ago, for which he tapped her. Some time afterwards she returned to a distant part of Ireland and was again several times tapped; after the sixth tapping the sac suppurated, and she was for many days in a dying state. For three weeks her death was almost momentarily expected. Nevertheless, she completely recovered, and was able to go about now as well as he ever remembered her. He thought it right to mention this case at a time when it was not quite determined whether ovariectomy should be legitimately introduced into surgery, not that he did not himself entirely adopt the view that the operation was one which should be legitimately introduced and looked on as an established operation.

Dr. BEATTY remarked that the case mentioned by Dr. McDonnell was not without example. Inflammation of the sac set in, pus was discharged into it, and like the case of hydrocele, the sac collapsed, contracted, and there was no further effusion of fluid. It was what used to be attempted by injection of iodine into these enormous sacs of ovarian disease, a process which he had himself used. On one occasion on the third injection of iodine, intense inflammation was set up and pus secreted as the result of the operation, and the woman finally recovered. He need not say that that operation had been abandoned now from the number of failures that followed it, and the number of successes that followed the entire extirpation of the sac. With respect to the use of the clamp, he would read a passage from the remarks of Mr. Spencer Wells, on the occasion already referred to. This point had occupied the attention of all ovariectomists. Some men preferred the clamp until a late period, and Mr. Wells, who had fought for it a long time, now seemed disposed to abandon it. The ligature of the pedicle had been adopted by Dr. Tyler Smith, and he had had the greatest amount of success in his operations. His invariable practice was to put a ligature on the pedicle and drop it into the pelvis. Mr. Spencer Wells observed—"With regard to the use of the cautery in ovariectomy the cases brought forward certainly proved that we had been taught an additional and successful mode of dealing with the pedicle. But it also convinced him that it should be an exceptional and not a general method. The number of cases

in which ligatures had been also required, the accounts of melting and flaming fat, the case required as to the precise temperature of the irons, the slowness of the searing, the effects of disturbing the eschar, and the very frequent supuration of the abdominal wall were very unsatisfactory. And the argument, that because out of twenty completed cases only two had died, therefore this success was due to the use of the cautery, was clearly untenable. For it was a curious fact that of the last twenty-two cases of ovariectomy in which he (Mr. Wells) had been able to secure the pedicle by a clamp only two had died, and one of these lived twelve hours, and died of cancer of the peritoneum, which was not detected before the operation." Mr. Wells had lately come round to the cautery. In the last letter he had from him he said, "I am this day to perform my two hundred and second operation." Of those, he had saved one hundred and forty lives, and he (Dr. Beatty) thought a gentleman who could say that was worthy of being quoted in the Surgical Society of Ireland.

Dr. McCLINTOCK believed the most important point in connection with the performance of this operation was the manner of disposing of the pedicle. Judging from the analogy of other cases in surgery, he thought that no one particular mode ought to be pursued, and that the surgeon must be guided by the peculiarity of each special case, as to what plan he should adopt, whether to retain the pedicle with a clamp, or divide it and drop it into the abdomen, as was done by Dr. Tyler Smith, or to use the actual cautery. With reference to the use of the ligature, perhaps the general opinion that the presence of the ligature on the abdomen was an exciting cause of peritonitis had been too hastily adopted.

Dr. BEATTY said that the pedicle had been ligatured and dropped back into the abdomen over and over again with great success. In one case, Dr. Tyler Smith found, on making a post-mortem examination, that the ligature was surrounded by lymph, and was not the exciting point of any inflammation in the peritoneum. In another case when the patient died of peritonitis, it was found that the spot in which the ligatures were, was the only part of the cavity that was not the subject of peritonitis—showing clearly that the ligature was not the cause of inflammation.

Mr. BANON said he had been asked whether this tumour was of traumatic origin? They knew nothing about that until after the operation, and therefore could not answer the question. If they had known what the mother told them before the operation, it might have inclined them to fix the growth from the left rather than from the right. With respect to the observations of Prof. Hargrave as to the absence of peritonitis after ovarian operations compared with operations for hernia, there was one reason which might account for it. The peritoneum, where an ovarian tumour was present, was accustomed to a foreign body, and this rendered it less likely to take on an active form of peritonitis. As to the treatment of the pedicle he fully agreed with what Dr. Beatty said, and also with the observations of Dr. McClintock, that the operation must vary according to the circumstances of the case. In such a case as the present the clamp would have produced embarrassment. His colleague, Dr. Hughes, wrote to the gentleman who assisted Mr. Spencer Wells to send him the newest irons for searing, and he sent them over and expressed his belief so strongly that this was the best mode of all that they were determined to pursue it. They had the irons ready and prepared, but when they came to examine the pedicle, the vessels were found to be so extremely large, the veins particularly, that they were afraid to trust to searing alone. With regard to the observations of Dr. McDonnell as to this operation not being yet completely recognized, he thought that where nearly seventy-five per cent. of the cases under the treatment of Mr. Spencer Wells had recovered, where, in many of those cases but a short period would have elapsed before the disease proved fatal if the operation had not been performed, where the operation was distinctly the cause of saving life, and where the proportion of recoveries was greater than in many other capital operations, there should be

no hesitation in recognizing ovariectomy, if it were not already recognized, as a legitimate surgical operation.

[We understand the patient has died since the report was sent to our office.—ED.]

#### MELANOTIC TUMOUR FROM A CALF.

Dr. JOHN BARKER said—Mr. President, I shall trespass but very briefly on the attention of the Society in bringing under their notice a tumour of a character not often seen in man, though occurring more frequently among the lower animals. It is what I would call a true melanoid deposit in a fibrous matrix. It was taken from the neck of a calf, and is remarkable for its size, its weight, its pendulous nature, and the appearance a section of it presents under the microscope. Tumours of this kind are sometimes found in animals having a white or reddish skin or coating of fur, and in these there seems to be an aggregation of pigment particles found in animals of a darker hue into one part. Persons, too, of a very white skin are more frequently affected, and in them moles are said to be the parts which change into melanoid tumours. In the lower animals it does not often affect the glands, and so may be of a local character. Though black deposits are found generally in more situations than one in man, it is associated with malignant disease. The tumour presents on section an intensely black colour uniform throughout, although it has been in spirit of wine for many months, and a microscopic examination showed minute pigment particles of about 1-10,000th of an inch in diameter imbedded in a fibrous network. Paget states that in melanosis in man the pigment particles are about 1-5000th to 1-3000th of an inch in diameter, which agree with what I have generally found, thus bearing some proportion to the size of the blood corpuscles; but in this case the particles are very minute, the blood corpuscles being about 1-4500th of an inch in diameter in the calf. I send round a sketch of their size and appearance in the microscope, and in my microscope on the table are some of the particles amplified about 900 diameters. The specimen was brought to me from the shambles, and it may be a very grave question how far animals thus affected are fit for human food.

## Correspondence.

### POISONING BY DISEASED VEAL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I ask you to publish the following imperfect account of some cases of poisoning by diseased or putrescent veal, which occurred in my dispensary district in June, 1866. I am sorry I have not preserved better notes of the cases, and that my time is so occupied at present that I can give but little of it to writing this statement. Dr. Cross of Strangford preserved full notes of the cases sent to the Union Hospital, and he also saw some of my cases, and he purposes, I believe, to publish his notes.

On the 23rd June, 1866, three persons purchased each a quarter of veal, in the Market-square of Newtownards from the same butcher. One of the quarters was taken to the house of a man called Smyth, about three miles from Newtownards, and used there. On Sunday, soup made of the veal had been used scantily by the family, and no bad consequences followed, but on Monday the veal itself was eaten by Smyth's family, and by two persons he had at the time assisting him in labouring a field, and all these persons took ill five or six hours afterwards in the same way—with vomiting, purging, burning sensation in the abdomen, thirst, a strong desire for cold drinks, occasional tormina, and a feeling of sinking weakness. On Monday though so ill they thought the purging and vomiting by removing the cause of the sickness would cure them, and they took no medicine, and on Tuesday the same notion prevented them seeking medical advice, but on Wednesday the 27th they procured a dispensary ticket, and all became my patients. I found Hugh Smyth, aged 63; Robert Kerr, aged 25; John Gibson, aged 10; Jane Smyth, aged 36; Ellen Headley, aged 10; Jane Armour, aged 3, Thomas Headly, a child, age not

stated; and the mother of these children also, whose name was not entered in the ticket, eight persons in all, all ill in the way described.

Hugh Smyth died on the evening of the 30th June, the sixth day after eating the veal, and Robert Kerr died on the morning of the 3rd July, eight days after eating the veal.

The skin of Hugh Smith, Robert Kerr, and John Gibson became blue to a considerable extent on Thursday the 23th, and with Smyth and Kerr, remained so, until they died; the blueness was best marked on the thighs and body, it disappeared on pressure, and did not depend on subcutaneous effusion of blood. The same blueness occurred a little later, and not to the same extent in the other cases. In none of the cases, so far as I observed, did the hands and feet become blue. In none of the cases was the breath cold at any time, and at no time was the discharge from the bowels like the rice water evacuations of Asiatic cholera patients. The intellects of Kerr and Smyth were clear up to very shortly before death. In none of the cases was there sopor coma, convulsions, epilepsy; no cutaneous eruption of any kind occurred in any of the cases, except a speck or two of vesicular eruption in Gibson's face.

Those who recovered were slow in regaining strength. There was nothing like the consecutive fever of cholera in any of my cases. I should have stated that the secretion of urine was arrested in all the cases while the purging continued, but when the purging stopped, there was no difficulty in getting the kidneys to act.

As to the treatment, I deem it unnecessary to detail it. I gave stimulants, astringents, cinchona bark, applied sinapisms, warmth, nourishment, and every means I thought likely to stop the vomiting and purging, and sustain the strength. I did not at any time give capsicum.

An Englishman called Troppe, bought one of the quarters of veal, and he and his wife ate a little of it fried at one time with bacon, and at another with beefsteak; they were ill after using it, and disliking its appearance did not consume it all. They suffered from pains in the head and back, and general unwellness. The Englishman had bathed in the sea on the day he first tasted the veal, and thought he had got the pains, &c., from bathing.

A woman called Cork bought one of the quarters, and her sister's family used the half of it, and her own family part of the other half; both suffered in the same way as Smyth's family. Cork's sister's family got a dispensary ticket on the 27th June, but before I got time to visit them they had gone to the Union Hospital. On the 29th June, I prescribed medicine for Cork, her daughter, and her father, they had been ill much as Smyth's family, but not so badly.

On the 4th of July I was examined at one of the sittings of an inquest held on the bodies of Smyth and Kerr, and gave it as my opinion that their deaths were caused by poisoning—the veal they had eaten, owing to disease or incipient putrescence, having acted as an irritant poison. I was asked to make a necroscopic examination of Smyth and Kerr, and declined. Dr. Armstrong removed the viscera, and these and some portions of the veal were examined by Dr. Hodges, of Belfast, but no mineral or vegetable poison was detected by him. I think it well that Dr. Hodges was employed by the Coroner, as his evidence—considering his acknowledged competency as a chemist—must remove all possible doubt from the case. At the last sitting of the inquest, on the 24th July, 1866, Dr. Hodges was not present, and his letter stating that he could find no poison was not admitted as evidence, though its contents were stated. The jury found that the deaths of Smyth and Kerr were caused by eating *poisoned* veal.

On the application of some parties a further investigation of the case before the magistrates was ordered by the law officers of the Crown, and this investigation, at which Dr. Hodges was examined, resulted in the case being sent to the Down assizes for trial.

At the Downpatrick assizes, opened on the 15th instant, the two butchers who had sold the veal were tried for having sold meat unfit for human food, and thereby caused the death of Hugh Smyth, and were acquitted. If I understood the Judge right, he stated, in charging the jury, that in order to convict the butchers, it must have been proved to the satisfaction of the jury—1st, that the veal was unfit for human food at the time they sold it; and 2ndly, that they knew it was so unfit at the time they sold it. His opinion seemed to be that there was considerable probability that the veal, owing to the hot weather, had undergone a change between Saturday and Monday, and this was more likely, as the Corks had used some of it on Saturday, and the Andrews and Smyths on Sunday, and

no bad effects had followed, and that it was on Monday the veal had produced the sickness which ended in the death of Smyth.

At the same assizes, the farmer who sold the calf to the butchers was to have been tried on a charge similar, I believe, to that made against the butchers; and when the Crown found that the evidence was not thought sufficient to convict the butchers, they entered a *non prosequi* in the farmer's case.

It had come out in evidence at the Coroner's inquest that the calf was dropped on the 17th June; that nothing was observed wrong with it until the morning of the 23rd June; that then the farmer found it ill, and went to a field and told one of his men to go in and cut its throat; that the man went to do so, but before he cut its throat it had ceased to move; that immediately after its throat was cut, it was taken to Newtownards, and sold for 4s. 6d. It also came out that the cow had been observed to be ailing two days before the 23rd; that this ailment was attributed to a wetting she had got; that she got no medicine until the evening of the 23rd, and that she died and was buried on the 28th or 29th June, I forget which. At no time had the calf been fed exclusively on its dam's milk, but on her milk mixed with the milk of two other cows. As to the disease of which the calf died we are in the dark; but there seems much probability that the cow died of inflammation of the uterus. I should have stated that it was also proved that the cow had not fallen off much in her milking until Saturday or Sunday, the 23rd or 24th. At one time I felt sure that the calf had died of the disease called "black quarter," as one quarter of it has not been traced, but from what I have heard I deem it probable that the whole four quarters had been sold. Something may yet, however, be discovered as to the missing quarter; it is not proved it was sold. Black quarter is well known here.

That veal in a diseased state, or in a putrescent state, is adequate to cause poisoning is well-known. That different effects would have followed in these cases from any other known poison, I think, may be safely affirmed.

Copper and its compounds would have been followed by coma, or convulsions, or paralysis, or jaundice, or faintings, or ulcerated gums. There were no such effects.

The compounds of mercury would have caused salivation, sore throat, or tremblings, or difficult deglutition, &c. There were none of these.

Arsenic would have caused irritation of the bladder and urethra, depressed action of the heart, palsy, or epilepsy, or a pustular eruption, &c. There were none of these.

Lead would have caused quite a different class of symptoms, as would oxalic acid.

No disinfecting liquid could have been put on the veal in such quantity as to cause poisoning after the washings to which it was submitted.

A vegetable poison would have acted more on the nervous system, and idiosyncrasy of constitution had nothing to do in the matter, as five or six families all suffered alike. That the cases were cases of Asiatic cholera cannot be held, as the symptoms differed from cholera, and as about fourteen persons who had eaten veal, and these alone, were attacked, and the disease progressed no farther.

The case seems to me a very important one, and, no doubt, will attract the attention of toxicologists. I am sorry it did not fall to the lot of some more competent person to give the cases I treated to the public.

I may mention that in the DUBLIN MEDICAL PRESS of the 9th and 16th of July, 1862, there are a number of cases of death caused by eating diseased veal given from the writings of Mr. Gamgee that are well worthy of perusal. I may also state what is perhaps indeed well known to all the readers of the MEDICAL PRESS AND CIRCULAR, that in 1862 Dr. Letheby published his opinion that the sale of the flesh of animals that had died, the flesh of animals that had been killed while suffering from inflammatory disease, and also the flesh of animals killed while ill of any lingering and emaciating disease should be prohibited as unfit for human food. It would be well were there some public enactment to this effect, many lives would be saved by it.—I am, sir, your obedient servant,  
D. JAMISON, M.D.

P.S.—A piece of intelligence which may amuse some of your readers has come to my knowledge through a reliable source. When a farmer has had a case or two of black-quarter among his calves, the following means of prevention is advised and practised here. He is to hang up in the kitchen chimney a bone of one of the legs of a calf that had died of the disease.

This will keep black-quarter from the homestead, it is alleged. Yet the schoolmaster is as busy here as any where else.—I should have stated that the bones of the quarter of veal eaten by the Smyth family were given to a large strong young dog, and produced vomiting, purging, and prostration in him, and that he did not recover quite, for about ten days.

#### CONSTITUTIONAL SYMPTOMS FOLLOWING SOFT CHANCRE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the MEDICAL PRESS AND CIRCULAR of the 3rd inst. there are some very interesting details of a case lately under the care of Dr. Angus M. Porter. In that case a sore throat (followed by severe inflammation commencing in the conjunctiva of the right eye) appeared a month after the primary affection. As Dr. Porter remarks, the whole case presented an "uncommon aspect" for one of constitutional syphilis. Taking into consideration the entire absence of any eruption of the skin, the absence of any ulceration in the throat, and absence of any other syphilitic symptom, I am much more inclined to regard the case as one of ordinary secondary inflammation in an enfeebled constitution than one in which secondary syphilitic disease followed a soft sore.—I am, sir, your obedient servant,  
HENRY LEE.

#### CONTRACTION OF THE LEG FROM GUNSHOT WOUND OF THE THIGH SUCCESSFULLY TREATED BY SUBCUTANEOUS DIVISION OF THE HAMSTRING MUSCLES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Believing that great benefit would be conferred on the community by the more general adoption of the practice of tenotomy which has been hitherto comparatively neglected, I beg to furnish you with the details of a case in which this treatment has been eminently successful, and by which a most deserving professional gentleman was restored to the use of his limb, although some few years ago he would be placed among the pitiable class of incurables.

Dr. Richard Vickery, Assistant-Surgeon of the 2nd Michigan Volunteers, whilst serving with his regiment at the battle of Petersburg, Virginia, in June 1864, was summoned to attend some wounded soldiers, and with that contempt for danger, and regard to duty, which always characterize Military Medical men, he hastened to render assistance to the sufferers, and whilst so engaged, was hit by a Minnie rifle-bullet on the external surface of the right thigh; the ball traversed the deep-seated muscles, grazed the posterior surface of the femur, passed between the principal nerves and blood vessels, and escaped in front about six inches above the knee-joint. Although none of the great arteries had been wounded, considerable hæmorrhage took place, and profuse suppuration, and some sloughing occurred, as a portion of the clothing had been carried into the wound.

The patient was, I presume, attended to as well as circumstances would admit of, but by degrees contraction of the limb took place, the leg was bent at right angles to the thigh, firmly fixed in that situation, and did not admit of extension, however the hinge-like motion of the joint still existed, and encouraged me to perform the operation, which subsequently proved quite successful.

(OPERATION, PERFORMED AUGUST, 1866.)

Putting the internal hamstring muscles forcibly on the stretch, a sharp-pointed bistoury laid on the flat, was passed in under the integument of the thigh, and carried over the internal hamstring, the cutting edge of the knife was then brought in contact with the semitendinosus tendon, which was divided; the same proceeding was adopted with the semimembranosus—the division of both tendons being attended with a perceptible snap; the knife was again turned on the flat, and carefully withdrawn from the aperture, which was closed by a pledget of lint; the tendon of the biceps flexor cruris was then divided in a similar manner.

In conjunction with my friend Dr. Hadden, we made such pressure on the knee-joint as brought the leg into a direct line with the femur, and retained it in that position by means of a hollowed splint, which extended from the middle of the thigh to the upper portion of the tendo achillo; the leg and thigh were then carefully bandaged, and kept in an extended position for about a fortnight; after a few days the external wounds were entirely healed, and but very little inflammation set in.

On examining the limb, we found that it had regained its

natural position. Amesburg's splint was then placed on the under surface of the knee-joint, and, by aid of the screw, the extension of the limb was gradually kept up for nearly two months, after which period Dr. Vickery was able to use the leg, and when last I saw him, he could walk about unaided, although he had been for months before the operation unable to move except on crutches.

By a newspaper, which I have lately received, I find he is perfectly restored to health, and the perfect use of his limb, and has been appointed to a surgeoncy in the army of the United States, in which position I am sure he will, if required, exhibit the same skill and humanity that distinguished him on a former occasion.—I am, sir, &c.,

DANIEL DONOVAN, M.D.

#### MR. BROWN AND THE OBSTETRICAL SOCIETY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me a word or two more in your excellent journal on the subject now uppermost in the profession. But first of all I wish to say that I am not a friend of Mr. Brown: so far from it, that I have never spoken to him, not even seen him at any time. On the other hand, I am not acquainted with any Member of the Council, nor have I spoken to any Fellow of the Society on the proposition before them, but take my views solely from what I have read at various times.

Leaving, then, the points at issue between the Obstetrical Society and Mr. B. Brown, and consequently forbearing to express any opinion as to the justness of the sentence passed on him by the Fellows in their vote on Wednesday evening last, there is one thing which must strike every one who attentively reads the charges and the reply, with a view of judging fairly of the case. No one can fail to see that the Council have acted, in one particular, most disingenuously, to say the least, towards Mr. Brown. After the discussion on Dr. Tanner's paper, he had evidently come forward and courted inquiry with regard to the operation in question. He it was who first offered to the *Lancet* on 3rd November last year, jointly with the editor of that journal, to nominate a committee to report on the subject, and agreed to abandon the practice if their verdict was adverse. Nothing resulting from this proposal, he offered to place twelve or twenty cases at the disposal of Dr. Tanner, who went to the Surgical Home and commenced the examination; but the *Lancet* of the 12th January urged the Council of the Society to appoint three gentlemen to investigate the point, and about the same time a similar recommendation was made by the *British Medical*, in consequence of which Dr. Tanner discontinued his visits, and Mr. Brown communicated with Dr. Meadows for the purpose of having a committee of enquiry appointed. Five Fellows were named, and Mr. Brown arranged to propose them, but, at the request of Dr. Meadows, left it to Dr. Hall Davis who had agreed to nominate the committee at the next meeting on the 2nd January, but who for some unaccountable reason had failed to do so. Mr. Brown then on the 7th January addressed a letter to the Council requesting a fair and impartial investigation, and offering every facility in cases in his own practice. After this, three weeks passed, and no notice whatever was taken of this letter, when a friend, who was a Fellow of the Society called on him and told him that several councillors instead of considering his proposal were agitating his removal from the Society. He then on the 31st January wrote to the President begging to withdraw his previous letter, when five days after one of the Secretary's wrote to acknowledge the receipt of both letters, and to say that as no meeting had taken place, they had not been before the Council. In the meantime meetings were held on the 15th and 25th February, and on the 27th a circular was sent to the Fellows, to Mr. Brown among the rest, to say it was the opinion of the Council that he should be expelled the Society.

Now what impression is made by these facts upon a candid and impartial mind? Is it not plain that Mr. Brown has been open, and that he has courted investigation? Has the Society reciprocated his openness? Suppose Mr. Brown deserving the brand they have endeavoured to put upon him, have they conducted themselves like fair and honourable men? Does not the feeling somehow or other insinuate itself into the mind, and will it not spread to every impartial observer, that instead of a just ground of condemnation, at bottom there was thorough prejudice and dislike. Or if such was not the case, and if they were perfectly justified in getting rid of Mr. Brown, still the manner in which it was done, explain or disguise it as they may, will be a lasting discredit to the Society.—I am, sir, your obedient servant,  
FAIR PLAY.

ANSWER TO MR. THOMPSON'S CRITIQUE OF DR  
CAPLIN'S ELECTRICAL SYSTEM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—In reply to the article referring to me, which appeared in No. 13 of the present volume of your valuable journal, I beg to say that I feel much obliged to the writer for giving me the opportunity of explaining to him what he does not appear to understand.

I admit with Mr. Thomson, that men have in all times propounded "ridiculous theories," but for my part, I do not find this wonderful, but merely simple, natural, and desirable, since it proves the avidity of the human mind for an increase of knowledge, so as thereby to arrive at the discovery of truth.

Were it otherwise, man's intelligence would remain at a stand-still, and science make no progress.

It is but too true that amongst the various theories and systems which have been introduced in course of time, many have proved to be very ludicrous; and it appears from what Mr. T. says, that he has come to the definite opinion that I am one of the unfortunate individuals who labour in the dark to arrive ultimately to shew in light of day their ridiculous presumption and ignorance.

As a matter of course, I cannot be a competent judge in my own cause, but, at the same time, I do not clearly see that Mr. T. has the right to assume the position of a critic on a subject of which it appears he has very slight knowledge. I do not know Mr. Thompson's age, nor the time he has devoted to the study of medical electricity; nor the experience he has acquired in the practice of that science. For myself, I must confess that I have spent about thirty years of my life, and laboured very hard too. Now, it appears that I have been mistaken during all that time. It is not certainly my fault, and I do not think Mr. T. is justified in turning my efforts into ridicule, and to cast reproach upon me for my perseverance. Whatever may be the result a man arrives at, it is either good or bad. I think it bad to try to discourage him. We must not contract the human mind. We must not frighten any man who labours in the field of science with the fear of being branded some day or other if he has not succeeded in his researches, because no one would endeavour to make new discoveries. On the contrary, I think it would be most rational, more christian-like, to encourage and help him, rather than to try to deter him. I think that, in all circumstances, indulgence is more becoming a gentleman than coarseness or insolence.

According to my humble opinion in matters of science, we should discuss coolly, bring forth arguments, and prove by good reason whether a man is either right or wrong, and to have the question decided by the verdict of a large, dispassionate, disinterested, and competent jury.

And, notwithstanding, we again find that the generality of men are sometimes wrong and mistaken. For instance, the great philosopher Pythagoras propounded the idea that the heart was the seat of the soul. Not only did he make innumerable disciples, but that idea was, for the time, adopted amongst most civilised nations; and this opinion was so strongly enrooted that even now it is said, in speaking of either good, bad, or indifferent people, that they have a good heart, a bad heart, or no heart at all; whilst the merest tyro in anatomy knows that this viscus is merely a hollow muscle, entirely destitute of intellect, thought, or mental faculties. Pythagoras was living B.C. 534—that is, 2451 years ago. That philosopher entertained a very erroneous opinion, although he was so scientific a man, and highly reputed for his extensive knowledge. Is he to be deemed a fool? Still his theory was wrong—very wrong.

By the side of this example we have an opposite one in Galileo, who was the first to discover the earth's rotation. No-body would believe him, and he was persecuted for having emitted an erroneous doctrine. However, he was right in spite of the universal opinion against him; and if truth had not prevailed in course of time, we should neither know nor be able to account for all the phenomena on our globe.

Another victim to common prejudices of certain individuals, or societies of men, was Harvey, who discovered the systematic circulation of the blood. He was ridiculed, and branded by his colleagues with the friendly epithet of madman; and the Royal College of Surgeons at the time exacted from the candidates before granting them a diploma an oath that they would neither adopt nor propagate Harvey's theory. Which was most in the right—the persecuted victim of truth, or the phalanx of his opponents?

I might also name Jenner, with his theory of vaccination,

and many others, who had to contend with the whole Profession before they succeeded in making the truth heard which they had discovered. It is well known that new discoveries and innovations of every kind have always met with opposition, nor do we know what effect the dread of this sort of perpetual war may have produced upon men of genius, but of timid dispositions. Perhaps many a noble truth has been lost through the intimidating influence of the many against one. Now, it is clearly evident that all the detractors of the systems above alluded to were perfectly ignorant of the fundamental principles to which they were opposed.

My theory is not a fabrication of my own. I found the principle on which it is based existing already in nature. There is nothing in it, then, of my own invention. What does belong to me is only the mode of application, and of that I do not make a secret.

Mr. T. is quite correct in supposing that I would put electricity in the place of what Hunter calls the "materia vitalis," or Müller the organic force. Only I would term it the "*vis universalis*," since, in my opinion, all the phenomena of the universe—vegetable and animal—owe their life to this subtle fluid, which is everywhere, and permeates all created nature.

I presume that Mr. T. will not deny the influence of the sun upon all that exists. Can he inform me what the sun is? Of what it is composed? and by what means it warms our atmosphere? and the earth's surface to its very centre? On the solution of that question we are all obliged to confess our ignorance. We may call its action, a power, an influence, if we please, but that is all; we cannot define it. Now, I ask, what power on earth, is more similar to that of the sun than electricity? It is a fluid incoercible, infallible, imponderable. Like the sun it produces light, heat, incandescence, ignition motion, &c., it is found everywhere, and is perpetually in action; yet, we know it only by its effects. But who can describe its nature if it is not an universal power, since living matter, animal and vegetable, is part of the universe. We are under its influence for a wise purpose. According to the Divine will, it is in us, for our good, even before our birth. It is, as it has been properly termed, the *vital principle*. If so, we cannot exist without electricity. Nevertheless, we may be deficient in electricity without losing life. For want of food we lose our strength, and we should die from starvation if our body was not supplied with new aliment. It would be the same if we were deprived of the vital principle, since, for want of it, we could not digest, for the chemical action would be suspended, and consequently life itself extinguished.

I persist in my opinion, that the human body is a decomposing machine. I use this word, because there is no other by which I can express my idea. I might call it a "vat," a "trough," a "cell," a "receiver," &c.; but, as the body moves, and is endued for the purpose of motion with the six mechanical powers, and even the three kinds of lever, I have called it in my lecture on Deformity a "living machine."

I regret that I could not make myself understood by Mr. T., though it is not to be much wondered at, as we have no technical language on the subject. I said in my article on Electricity, that it is cause and effect, and effect and cause.

I will endeavour to explain myself more fully that my meaning may, if possible, be apprehended.

It is a fact established and founded on scientific data, that no decomposition takes place in nature without evolving electricity, but sometimes this takes place in so small a quantity that a delicate electro-meter is required to ascertain its presence, still it is there, and is consequently the primary cause. But, according to the nature of the substance in decomposition, and the arrangement of our apparatus, we can increase electricity as we like, and thereby create a power. Thus, decomposition is the cause, and its effect a power.

Then, we employ that power for again producing decomposition; in this case electricity becomes as an active cause of further decomposition.

Lastly, Mr. T. arrives at the conclusion that it would be more rational to attribute the formation of electricity to the invariable processes which are constantly going on during life. In that respect, we are of the same opinion. I shall conclude, therefore, by observing that if Mr. T. has not understood me, the fault is probably my own; but it is difficult to be explicit when we are limited for space.

It may be very absurd, as Mr. T. says, to compare the body to a steam-engine, and the stomach to a boiler; but it is the best simile I can find to express my idea, for the most familiar examples often illustrate our thoughts the best.

As I before remarked, I cannot assume the right to be judge

in my own cause, and can only say that it was very far from my intention to amuse myself on chimeras, or on fantastic conceptions. I have worked hard to establish my theory by well-ascertained facts, and I scarcely believe that my researches are merely due to a "fertile imagination."

At all events, I thank Mr. Thompson for his *critique*, which is written conscientiously and in a cordial spirit, and I shall be happy to hear from him again.

If he will do me the favour of visiting my establishment, I shall be proud to afford him the means of investigating more fully my system and judging of it for himself.—I remain, dear sir, faithfully yours,  
J. CAPLIN M.D.

[We must do Dr. Caplin the justice to observe that in this and former correspondence he has put forward the empirical practice, which he advocates in a fitting spirit of scientific discussion, and not at all in the tone of narrow-mindedness usually adopted in such controversies.—ED. M. P. & C.]

### FEMALE PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As it is very important to female physicians that the credentials of every woman assuming their office shall be clearly known and thoroughly proved, I think it right to forward to you the enclosed statement, made by order of the Surgeon-General of the United States' Army, respecting the alleged services of Mary E. Walker, whose proceedings in London will be most deplored by those who most earnestly desire to see medicine recognized as a profession for women:—

"Surgeon-General's Office, Washington City,  
"January 2nd, 1867.

"In the winter of 1863 Mary E. Walker was furnished with transportation to Louisville, Kentucky, to report to Assistant-Surgeon General Wood, who stated he could give her employment as a nurse. She was sent by him to Medical Director Perin, who ordered an examination as to her professional qualifications, and reported her incompetent for any higher position than female nurse. She was subsequently put on duty with the wounded, taken prisoner, and carried to Richmond, and released, receiving the pay of a contract physician from the time of her capture until her release.

"By order of the Surgeon-General,  
"C. H. CRANE, Assistant Surgeon-General,  
"United States' Army."

I am, sir, yours obediently,  
A MEDICAL STUDENT.

Boston, Massachusetts.

## Medical News.

LIST OF ENTRIES IN THE BRANCH MEDICAL COUNCIL (IRELAND) for the month of March, 1867.

Beckett, Alexander, Moneymore, Co. Londonderry, M.D., Univ. Glasgow, 1852.

Watt, Thomas, Mawhinny, Ballyjamesduff, Co. Cavan, M.R.C.S. Eng., 1867.

Hanna, James, Peter's Hill, Belfast, M.R.C.S. Eng., 1863.

Maier, Nicholas, Cootehill, Co. Cavan, L.R.C.P. Edin., 1866; L.R.C.S. Edin., 1866.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.—Seventh meeting—Session 1866-67. Wednesday, 17th April, 1867, tea at eight; chair to be taken at half-past eight P.M. Communications.—1. Dr. Marcus Eustace.—"Symptoms diagnostic of recovery in the different forms of Insanity." 2. Dr. Head.—"Notes of a case of Fatty Degeneration of the Diaphragm." 3. Dr. Hughes.—"A Case of Paralysis."

ST. MARY'S HOSPITAL.—The anniversary festival of this charity was celebrated last week at the Albion Tavern, City, under the presidency of Lewis Lloyd, Esq. At the conclusion of the dinner, the usual loyal and patriotic toasts were proposed by the chairman, and received with customary enthusiasm. In proposing the toast of the evening the Chairman said that the institution was established in 1851 for the relief of the sick poor; and since that time the total number of patients of all classes who have received relief at the hospital was 219,722, amongst which were upwards of 500 cases of severe accidents. The hospital at present contained 150 beds; and the completion of the "Albert Edward" wing would fur-

nish accommodation for an increased number of patients, and would also enable the governors to establish a ward for children. The income for the year ending December 31, 1866, was £3756 and the expenditure £8700. The Chairman, after an eloquent appeal on behalf of the funds of the charity, concluded by proposing "Prosperity and Perpetuity to St. Mary's Hospital." The toast was drunk with great enthusiasm, and the Secretary afterwards announced a list of subscriptions, amounting in the aggregate to nearly £1000; of which the Chairman contributed 200 guineas, Mr. J. P. Heywood, £100, &c. A number of other toasts followed, and the proceedings, which were enlivened by a selection of vocal music, terminated at an early hour.

### NOTICES TO CORRESPONDENTS.

Communications to the London Editor should be addressed to 20 King William-street, Strand; to the Edinburgh Editor, at MacLachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

Dr. Kidd.—Owing to pressure on our space, your paper must stand over for a week or two, when it shall be inserted if found suitable for our columns. In future, please address the "London Editor" at the office as above. Dr. Kidd would also oblige by writing a little more legibly.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Would you kindly inform me if, having vaccinated a child over the age mentioned in the Compulsory Act, or an adult operated on for the first time, I am bound to send a certificate to the Registrar.—Your obedient servant,  
T. W. M.

[The Compulsory Vaccination Act refers only to children born since the 1st January, 1864, and the 3rd section provides that the Medical Practitioner who vaccinates a child so born should send a certificate of same to the Registrar. No penalty is provided for neglecting this duty.—ED. M. P. & C.]

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your impression of the 27th March last, I notice Mr. Blacklock in a letter alludes to Mr. Johnston's "interesting and instructive case of protrusion of the intestines through an abdominal wound," and likewise refers to a case that had occurred to him. I think these cases worthy of our greatest attention, as heretofore the reference has been scanty, and rather unsatisfactory, in regard to our knowledge of such cases.

I lately had the pleasure of hearing from Dr. Mair, at Banda Orientale, that he had treated three such cases with perfect success. Two of the cases were adults. The other was a girl. In the treatment, after replacing the bowel, he transfixed through the skin of the abdomen the protruded omentum by needle and ligature, constructed it with the ligature, and afterwards removed it by the knife. A simple compress was then applied with a bandage. The only drug administered was a dose of opium after the operation. The cases recovered admirably.

I hope Dr. Mair will ultimately publish the nature and circumstances of the cases, as I understand it is his intention to do.—I am, yours, &c.  
JAMES L. KING, F.R.C.S.E.

### MEDICAL APPOINTMENTS.

BARTLETT, T. H., M.B., has been elected one of the Surgeons to the General Hospital, Birmingham.

BATTEN, R. W., M.D., has been appointed Physician to the Gloucester Infirmary, vice T. Evans, M.D., resigned.

BRAMLEY, L., F.R.C.S.E., has been appointed Consulting Surgeon to the Halifax Infirmary, on resigning as Surgeon.

CARTER, W., M.B., B.Sc., LL.B. Lond., F.R.C.S.I., has been elected Honorary Medical Officer to the Northern Dispensary, Liverpool, vice Dr. M'Caull, resigned.

DRAPEL, W., M.R.C.S.E., L.S.A., L.M., late Resident Obstetric Assistant at the Middlesex Hospital, has been appointed Resident Medical Officer to the York Dispensary, vice T. Collier, resigned.

LANGSTAFF, C., M.D., M.R.C.S.E., has been elected Surgeon to the Royal South Hants Infirmary, Southampton, vice J. King Sampson, resigned.

M'DOWEL, B. F., M.D., York-street, Dublin, has been elected to the Chair of Materia Medica in the Ledwich School of Medicine, Peter-street.

MOON, R. C., M.R.C.S.E., late House-Surgeon at the Ophthalmic Hospital, Southwark, has been appointed Assistant-Surgeon to the Hospital.

NOWELL, W., M.R.C.S.E., has been elected Surgeon to the Halifax Infirmary and Dispensary.

SHORTO, J. R., M.R.C.S.E., L.S.A.L., has been elected Assistant-Surgeon to the Royal South Hants Infirmary, vice C. Langstaff, M.D., elected Surgeon.

SIDDALL, J. B., M.D., has been appointed House-Surgeon to the General Hospital, Bristol, vice W. Harris, M.D., resigned.

STREATFIELD, J. F., F.R.C.S., late Assistant-Surgeon in the Eye Department, University College Hospital, has been appointed Ophthalmic Surgeon to the Hospital.

VALLANCE, T. J., M.D., has been appointed Medical Officer to the West Ham Union Workhouse, Essex, vice J. T. Vallance, M.D., resigned.

WARREN MEYRICK, E. W., M.R.C.S.L., &c., has been appointed Senior House-Surgeon to the Ardwick and Ancoats Dispensary, Manchester, vice John Moir, L.R.C.P.E., &c., resigned.

WICKHAM, R. H. B., L.R.C.S.E., has been appointed House-Surgeon to Gray's Hospital, Elgin.

## Original Communication.

## CASE OF "BLACK DEATH."

By JOHN HAWTREY BENSON, M.B., L.R.C.S.I., L.K.Q.C.P.I.

At the hour of 11:45 on Tuesday night the 9th inst., a note was received from the Purser Student of the City of Dublin Hospital, requesting me to visit a patient who had been admitted that evening for me, and who had been suffering from very severe diarrhœa for some hours.

On my arrival at the hospital, I found that the patient was a boy aged 14. The means used to check the diarrhœa had succeeded, and he was then in a quiet tranquil sleep; no stertor, respiration perfectly free, pulse frequent and feeble, but not remarkably so. Nothing was known of the boy beyond the fact that he had been ill for a few days, and that when admitted he was dull, drowsy and stupid. As there was, accordingly, no history, and no indication for treatment of any kind, I did not rouse him, and merely left some general directions to be followed in case of a renewal of the diarrhœa. He had an exhausted appearance, and a sallow dusky hue, but no spots or discolourations were at that time visible on the face, chest, or hands, the only parts exposed to view. He remained sleeping tranquilly for over an hour after I had left the house, but after that got restless, and had considerable jactitation. About half-past one in the morning (Wednesday), dark spots began to appear on the face first, and soon after on the arms and legs. The spots rapidly spread, and the patient quickly sunk, notwithstanding active stimulant treatment. He vomited twice, accompanied each time with a convulsion, and by six o'clock the same morning he was dead.

After his death I learned the following history:—

He was an indoor servant of regular habits, and good general health.

About a week previous to his admission he had a quarrel with a fellow-servant, when the latter lifted him off the ground, and then flung him down with violence, but he came on his feet.

No effects apparently followed this, and he seemed to remain for some days quite well up to Sunday evening, the 7th inst., when he began to feel slightly indisposed. On Monday morning, 8th, he had a stupid aspect, and is described as sitting over the fire for the greater part of the day, and poking it abstractedly, without any apparent object. On the evening of the same day Dr. Head saw him. He was then sensible, put out his tongue when desired, but did not answer when spoken to. His fists were clenched. His bladder was distended, and with the aid of a catheter, about 16 oz. of urine, slightly ammoniacal, were drawn off. A turpentine and fœtid enema was also ordered.

Next morning (Tuesday 9th) the enema was found to have acted freely. The boy answered questions put to him, but was still dull and stupid, and after being disturbed, settled down again into sleep almost immediately. That evening he was taken into hospital, and the Purser Student who admitted him describes him as having a drunken appearance, and inclined to go to sleep even in the hall of the hospital. A few hours after this the diarrhœa mentioned above came on.

*Post-mortem Examination.*—About thirty hours after death the post-mortem examination was made, in which I had the able assistance of my colleagues, Dr. Geoghegan, Dr. Benson, and Mr. Tuffnell, and of Dr. Head.

The body presented the following characters:—

Rigor mortis rendered the extremities quite rigid; the green colouration of commencing decomposition was already well-marked on the abdomen; every part of the body had purple spots on it; the chest and upper part of abdomen were least affected; the ears, the sides and back of neck, and the legs were most discoloured; on the legs, more especially than on any other part, there were seen three well-defined degrees of discolouration. Firstly, there was a ground, so to speak, of rather light purple, which had left but few patches of healthy-coloured skin. On face, chest,

and upper part of abdomen this ground did not appear at all. Secondly, very much less-widely diffused, there were darker spots, varying from the size of a threepenny piece to that of a crown, of very irregular shape. And thirdly, there were a few very dark purple spots, almost black, scattered over every part of the body. The spots on the face, front of neck and chest, were, with few exceptions, small and rather dark—some not larger than a line in diameter. The tips of the ears were of a very dark purple, almost black; the conjunctivæ had a few dark, well-defined, purple spots, especially the palpebral portion of that membrane.

The gums had a few slight patches, but the inside of the mouth and of the fauces were quite free.

On the soles of the feet the spots were not quite so numerous as on the dorsum and sides, and were rendered paler in appearance by the thickness of the cuticle. The whole of the back of the body was of a nearly uniform darkish purple, a good deal of which was, no doubt, a post-mortem effect. The body had been lying on its back since death. Some of the darker spots could be seen through this purple ground, and some parts were pale, as the nates and back of chest, on which the weight of the body pressed, but even there the darker spots remained unaltered.

On removing the calvarium the dura mater presented an unusually bluish tint, and its sinuses and veins were unnaturally distended. When this membrane was cut away, the veins ramifying on the surface of the brain were found a good deal congested; but neither on the upper or under surface of the brain, nor in its membranes, was there the least sign of recent inflammation to be found. No lymph, no pus, no effusion of any kind on or under the arachnoid. When cut the substance of the brain was slightly softer than is natural, but scarcely congested. Each lateral ventricle contained about a drachm of bloody serum. The choroid plexus was congested.

The spinal chord presented appearances similar to those of the brain. The spinal sinuses were very much congested. The veins on the surface of the chord were also turgid throughout. The substance of the same was of natural consistence, and not the least trace of inflammation was anywhere observable.

On the surface of the lungs, and throughout their substance, were found numerous well-defined black spots, about the size of a millet-seed, very uniform in size and appearance, and at a distance from each other averaging about a quarter of an inch. They were not at all like the spots on the skin or conjunctiva, but had rather the character of punctiform melanosis. There was some slight congestion, but otherwise the lungs were natural.

In the pericardium about an ounce and a-half of bloody serum was found, but no trace of inflammation.

The left ventricle and auricle were quite empty. The right cavities were tensely distended with a uniform, loose, "black currant jelly" coagulum of blood. No tendency was shown for the fibrin to separate from the other constituents of the blood. The heart in all other respects was quite natural.

In the abdomen the liver was normal in size and consistence, but remarkably dark in front, for a distance of from one to three inches from the free edge, the colour fading off gradually into the natural hue of the healthy gland.

The gall bladder was fully distended with bile. The stomach, beyond being somewhat congested, was natural. The bowels showed very little sign of congestion.

The solar plexus presented a perfectly healthy appearance.

The kidneys were slightly congested. Some serous infiltration was found in the areolar tissue around.

The spleen was slightly congested—nothing more. A portion of the blood found in the right auricle I submitted to the microscope, and the result of my examination completely coincided with what was observed by Dr. John Barker, who kindly examined it also.

The following is his report:—

"The blood presents no very distinctive characters under the microscope. The corpuscles in many parts present a

crinated appearance on the edges, so far as to give the appearance of those bodies breaking up, under pressure, into several parts, similar to what takes place when blood-crystals are about to form."

This may have been a post-mortem effect. No white corpuscles were apparent in the field of the microscope.

*Observations.*—This case presents one of the forms in which the terrible disease now popularly called "The Black Death" has begun to appear amongst us.

I think we have not yet found a satisfactory name for it. It does not much resemble the Black Death of the middle ages, as it wants the "inflammatory boils and tumours of the glands," "the buboes in the axillæ and groin," the extreme contagion, "the expectoration of blood," and other symptoms which marked that disease; having, in fact, little in common with it except the black spots, which are only mentioned as having occurred "in many cases."

Neither does the name "Febris Nigra" seem very appropriate, scarcely any of the characters of fever being exhibited by it.

It has been supposed to be some stage or modification of cholera, but here again the absence of cramps, and of change of voice, the exceptional occurrence of vomiting and purging, and even the marked difference in the colour and in the expression, seem to separate it from cholera. It remains for further observations to be made before we can say whether the diarrhœa which occurred in the case now reported was connected directly with the disease in question, or was merely an accidental complication.

To the theory of those who are of opinion that this disease is connected with cerebro-spinal meningitis, this case at least lends no support.

There is evidently some poisoned condition of the blood, but of its exact nature or cause there is, as yet, no proof. Neither is there, as yet, any reason to believe it to be contagious.

"Malignant purpura" conveys, perhaps, a better idea of the disease than any of the names that have yet been given to it.

## Hospital Reports.

### ST. BARTHOLOMEW'S HOSPITAL.

**MALIGNANT DISEASE OF THE SUPERIOR MAXILLARY BONE; EXTIRPATION OF THE BONE; SECONDARY HÆMORRHAGE; LIGATURE OF THE COMMON CAROTID ARTERY; DEATH.**

Under the care of Mr. HOLMES COOTE.

ANGUS K., æt. 45, cellarman, was admitted into St. Bartholomew's Hospital July 31, 1866, under the care of Mr. Coote. He was a pale, thin, and badly-nourished man, with a feeble circulation; and he had suffered a good deal from exposure to cold.

*History.*—States that about January of the present year, after unusual exposure to cold, he suffered extreme pain, of a neuralgic character, in the left cheek. This, he thought, was due to a carious tooth, which he had removed about a fortnight afterwards, but the pain still continued. About the beginning of June he first noticed the swelling in the mouth, and a small tumour first showed itself below the left lid.

Father and mother died from natural causes. Brother and sister healthy.

Aug. 4th.—Mr. Coote removed the upper jaw in the usual manner. The wound healed by the first intention and he went on favourably until Saturday, Aug. 18th, when hæmorrhage to about eight ounces came on, but ceased in about five minutes on ice being applied.

21st.—Hæmorrhage again returned to the extent of about four ounces, and was again arrested by the application of ice.

23rd, 9.30 p.m.—Mr. Orton, the House-Surgeon, was called up into the ward, and found him quite blanched from the hæmorrhage, which had again returned to an alarming

extent. The pulse was not perceptible at the wrist. Mr. Orton at once proceeded to tie the carotid artery above the spot where it crosses under the omo-hyoid. The hæmorrhage was at once arrested. He was then given some brandy, and the pulse became perceptible at the wrist. He conversed, and expressed himself comfortable.

At 11.30, about one and a-half hours after the operation, he suddenly became faint, and died under a struggle.

*Post-mortem Examination* of the body revealed ulceration within a branch of the internal maxillary artery.

### LONDON HOSPITAL.

**INTESTINAL OBSTRUCTION BY VOLVULOUS AND "BAND." EXPLORATORY OPERATION.**

Under Care of Mr. MAUNDER.

W. C., aged 66, was admitted with symptoms of intestinal obstruction on September 18th, 1864. Seven days before he had been seized with pain in the right iliac region, and had suffered from constipation and vomiting ever since. He was the subject of a reducible inguinal hernia on the left side, which had existed many years, and also of a bulging in the right groin both above and below Poupart's ligament; here was also a cicatrix, the result of an operation for strangulated hernia, performed five years previously by Mr. Ward.

Mr. Maunder came to the conclusion that the symptoms were not due to external strangulated hernia, neither was the obstacle to be found in the rectum. Two grains of opium were ordered at once, and a little brandy occasionally. Nine hours later the patient expressed himself better.

September 19th—Vomiting has recurred, and now, in consultation with Mr. Luke, it was deemed right to explore the abdomen. This was done over the right iliac fossa, and the finger introduced, detected a "band" passing in a direction from the right sacro-iliac joint forwards, to be attached near the internal abdominal ring. Intestines of a greenish hue; serum of a fæcal odour. The band was carefully torn across and the wound closed. Death resulted seven hours after operation, and the ninth day from the attack.

*Post-mortem* disclosed a volvulus of small intestine, about a portion of ileum, to which one end of the "band" was attached. Slight traces of peritonitis.

### THE MEDICAL ASSOCIATION

OF THE  
COLLEGE OF PHYSICIANS, IRELAND.

SECOND NIGHT'S PROCEEDINGS.

THE debate was resumed on Friday evening at half-past eight.

THE PRESIDENT OF THE COLLEGE in the Chair.

Sir DOMINIC CORRIGAN, having been called on by the President, observed that there was one very gratifying feature in their debates, namely, that they came there to elicit truth, not to support their own opinions, and he was sure there was not a man amongst them who would not sacrifice his opinions if he were convinced that those opinions were wrong. The first matter he wished to direct their attention to was the map of Ireland, which he had placed before them. It represented Ireland, divided by a line from North to South, rather an unusual division. All the towns that were visited by the epidemic of 1848, '49, and '50, were marked black—that is, the towns of 2000 inhabitants and upwards, for they were obliged to put some limit to the returns. All the towns not visited were marked red. A very remarkable circumstance for which he was not prepared, was that, on the left-hand side of the line—that is, the western side of Ireland

—there was scarcely a red dot, while, on the right-hand side, they were in large proportion; and the proportion was this, that in Ulster one-half of the towns escaped, in Leinster one-fourth of the towns escaped, in Munster one-eighth of the towns escaped, and in Connaught not one escaped. He was struck by this remarkable fact, that those portions of Ireland on the right side of the line, where there were manufactures, trade, commerce, industry, roads, and railways, presented a congeries of towns, of which from one-eighth to one-half escaped the ravages of cholera; while, in the West of Ireland, where there were no manufactures, no commerce, few railways, and little intercourse, not a town escaped. This was a remarkable fact, and he alluded to it in reference to a discussion which took place on cholera some time ago, when Professor Haughton stated that he was nearly converted to his (Sir Dominic Corrigan's) view, namely, that contagion was not an all-powerful influence in spreading the disease, were it not that he was convinced that cholera was brought to the West of Ireland by the reapers who caught it in England. He would not dwell further on this point than merely to narrate some facts, which would sufficiently show that these poor men did not, in addition to their other misfortunes, carry cholera on their backs; and having shown that, he thought he would be entitled to claim the gentleman to whom he referred as a supporter of his views. On looking to the report from which that map was taken, he found that the first appearance of cholera in Connaught, in the year 1849, was on the 7th of February, and that visitation extended through the intervening months to September of the following year. The cholera broke out in England in 1848. Now, the Connaught reapers who went to England in 1848, returned to their own country about July or August of the same year. The first outbreak of cholera in Connaught was in February, 1849. Taking those dates into consideration, they should then be forced to the conclusion, if they admitted Professor Haughton's views, that the reapers, having returned to their own homes in August, 1848, contrived to keep cholera as a latent burden until February, 1849. It was utterly impossible to hold that view, and he considered the question of dates to settle the matter—namely, that the Connaught reapers did not carry the disease from England in 1848, inasmuch as it did not break out in Connaught until 1849. In reference to the influence of contagion, they must take the *pros* and *cons*. He was not an advocate of any extreme doctrine one way or the other in the matter. He would mention some facts which had made an impression on his mind. The police force of Dublin consisted, in round numbers, of 1000 men. Of these, about 250 resided with their families, and 750 lived in barracks. It was an instructive fact that there were only eight cases of cholera among those thousand men, and of these six occurred in barracks, and two of policemen residing in their own dwellings. Now, of all the men in Ireland who were exposed to cholera, whether from their duties in places where cholera prevailed, or their contact with the sick poor and criminals, there were none more exposed than the police, and yet, out of 1000 men, there were only six cases of cholera, and four of these occurred in suburban districts. Again, take the workhouses. Dr. Minchin informed him that the North Union Workhouse contained about 2,000 inmates. How many cases of cholera occurred in that workhouse during the late epidemic?—and let it be recollected that the inmates of a workhouse were perpetually changing, and of all places a workhouse was, therefore, peculiarly exposed to the chances of contagion. Only two. He might mention another curious fact. Impure water had been much and often dwelt on as a cause of spreading cholera, and yet here is the description of the water used in the North Union Workhouse, in which only two cases of cholera occurred, given in the January number of THE MEDICAL PRESS OF 1840, by Dr. McDonnell, Poor-law Commissioner:—"A year and a-half ago I saw the basin emptied for the purpose of cleansing it. It is not possible by description to convey an adequate idea of the abominable comport, from one to two feet deep, that formed the bottom of it.

Gay's cloacina might, without regret, have deserted Fleet Ditch to wallow in its more congenial filth." He (Sir Dominic Corrigan) could fully corroborate that statement. The supply is still from the same source; and he mentioned it to show how cautious they ought to be in taking up water, contagion, or anything else to account for the spread of cholera. The village of Kilcock is full of beggars, and surrounded by bogs. In that village, from 1832 to the present time, a case of cholera had never appeared. If they turned to the clergy, a class much exposed to the influence of cholera, what did they find? Of the Established Church there were in Dublin seventy-six clergymen, and of the clergy of the Roman Catholic Church 137—making, in round numbers, 200. How many of them died of cholera? Not one. Of the medical profession, physicians to workhouses and dispensaries, how many died? Not one. If they turned to Sir Patrick Dun's Hospital they found that not one died. Among the authorities connected with that Hospital, there was one who had given himself heart and soul to the work of caring the poor, and had exposed himself without intermission to all the dangers of cholera—Professor Haughton. He did not die (laughter and applause); not one of the Physicians of the Hardwicke Hospital, or of the Mater Misericordiae Hospital, died; and not one of the Sisters attached to the latter institution, who bent over the dying, and devoted themselves so assiduously to attendance on the sick, caught the disease. Dr. Hayden had adduced two cases as evidence of the paramount influence of contagion. One was that a man said his wife had been in a cholera lodging-house. Now what a cholera lodging-house was he really did not understand; but he would ask his friend to remember that in estimating what was contagious and what was not, if they derived their information from one or two cases only, they might be led astray. He thought if his friend Dr. Hayden would consider the question again, he would, perhaps, not come to such a positive conclusion from two cases. The other case which he adduced was where a man derived his information from a cabman. Admitting the facts to be true, he submitted they were not sufficiently conclusive to found upon them the theory that cholera was eminently contagious. Suppose a man tried to relieve a friend who had got lumbago by rubbing him, and that he got lumbago, it might be said he got it from contagion. He adduced this to show that, in coming to a conclusion as to contagion or not, they could not derive a satisfactory conclusion from one or two cases, but must draw their inference from an immense number of facts. It was the only way in which they could avoid error. If one thousand cases of lumbago occurred from attending lumbago patients, then, indeed, they might say that lumbago was contagious, but they could not come to such a conclusion from one or two cases only. Dr. Hayden had alluded to the island of Réunion and to Greece; but from his experience he could say, that of all the countries in Europe in which it was impossible to carry out anything, Greece was entitled to the palm, and as for carrying out quarantine in Greece the thing was utterly impossible. The officials were most corrupt, and he was told at one of the ports that if he paid a drachma to the custom-house officer, he might pass in anything he liked from Beelzebub to Black-death (laughter). In the Cyclades, islands of Greece, there were ports frequented by steam-boats from all parts, and there were to be found Copts, Egyptians, Turks, and the nastiest set of human beings he ever saw. It would be perfectly impracticable to carry out quarantine there, and in fact it was not carried out in Greece. The conclusion he would arrive at, was not to take an extreme view of the question. He did not feel himself authorized to say that cholera was, or was not, contagious. He believed almost that any disease might become contagious. What he desired to convey was that contagion in cholera was an element far less powerful than in scarlatina or typhus. If they adopted the other view, and held that contagion was so powerful an element that our hospitals were to be closed against cholera patients, they would do a great deal of harm to mankind, both in its social relations and in its mari-

time interests. They should, he thought, look on cholera as a disease in which contagion might become an element, but its contagious nature had never yet been demonstrated. They would commit a great error if they elevated contagion as an influence beyond all others. The practical view he would adduce was this—that when cholera came among us it should be treated as any other evil; that even admitting it was contagious it was less so than scarlatina or typhus. A gentleman, for whose opinion he had a great respect, said he had been disappointed, that he had come there to listen to some improvement in treatment. Now, he looked on the debate, so far as it had gone, as the greatest compliment that could be paid to the Dublin School of Medicine—that it was eclectic; and he thought the great compliment to be paid to it was this, that it had not been lowered as other Societies had been, by men coming forward and saying that they had discovered this, that, and the other thing as a cure. There was one argument which he had often heard put forward, that cholera must be in the air, or in the water, or in the earth, and if it was not in the air inhaled by our lungs, it must be in the water taken in by our digestive organs. But did we know all the powers in nature? Might there not be some which we did not know and could not understand? It was within his own recollection that there was a time when we only knew with regard to light that it contained the rays revealed by the prism. Now it was known that there were *actinic* rays, calorific rays, and magnetic rays. A few years ago we knew nothing of ozone, iodine, and bromine. It was better for them therefore to say that as yet they knew not the cause of cholera, than to presume to come forward and say they had arrived at certain knowledge. Let them hope that by observation and reflection, by steadily cultivating those faculties which Providence had given them, they might ultimately arrive at the knowledge of the mysterious powers by which this disease, like other phenomena, spreads itself over the world. (Applause).

Mr. J. S. COMYN, Assistant-Surgeon Royal Artillery, said—As an Army Medical Officer, and an old pupil of Sir Dominic Corrigan, he would say a few words with respect to his experience of cholera abroad. He was quartered at Malta during the epidemic of 1865, and he had been constantly placed in positions half-way between India, where cholera was endemic, and this country, where it paid periodic visitations. He thought the Military Medical Officers who had spoken of cholera in India had described correctly the state of things there—that the disease struck localities, and that one passing through them was liable to be attacked by it; but in other places he thought that it travelled by human intercourse, and was conveyed by contact. In Malta in 1865 he had charge of a brigade of Artillery; they were quartered, women and children as well as the men, close to the Lazaretto of Valletta. About the middle of May there was a great alarm of cholera, and towards the end of the month the Maltese who lived at Alexandria began to pour into Malta. No cordon was established until the 14th of June, and on the 22nd of June Medical Officers were attached to the Lazaretto. They did not know therefore the exact commencement of the disease, for it was admitted that it might have been introduced by the choleraic diarrhoea, which might have been brought in by those persons. The first case broke out among his own regiment. On the 20th of June, a child was attacked and died. On the 21st of June he saw another patient. They were taken from a place adjoining the Lazaretto, which had been assigned to the married people, and which was badly drained and unhealthy. The disease occurred in six cases. On the 28th of June eight days after the outbreak, for there was at first a difference of opinion among the officers, whether it was cholera or not, he reported that the battalion should be removed to a long distance. This was not done until the 1st of July, and instead of being removed to a distance they were taken to Valletta, when five were attacked. A woman attending some of the patients was struck down by cholera. A few days after her death her child was

sent to Valletta; one of the people who took care of the child died, another was attacked but survived. Another person living within a few yards of them caught the contagion and died. The disease went into the house of an officer whose wife and maid-servant took the disease, and the latter died; and, although cholera had not broken out last year in Malta, yet in that very house a case of cholera in all its symptoms similar to the others, except in the immediate danger of death, took place and was attended by him. With regard to India, Malta, and Dublin, the disease seemed to exist under different conditions. At Malta and other places to which it did not naturally belong, he believed it was carried from one person to another. The case of Sicily afforded a strong proof of this. There was no cholera there in 1865 when vessels coming from other parts were rigorously excluded; but last year the disturbed condition of the island obliged the Italian Government to send troops into it, and the introduction of cholera was the result. With regard to the introduction of the disease into Gibraltar he might say a few words:—The 22nd regiment started from Malta for Gibraltar, on the 6th of July, six days after the cholera had been duly reported by him. Fourteen days after that the first case of cholera occurred in that regiment, and spread from it through the town. Of twenty-six Medical Officers who were present there, many of them men of long Indian experience, he did not believe that one was a non-contagionist. His experience was that men well nourished, young and strong, were not so liable as others to the disease, and might attend the sick with impunity as did the Medical Officers, but the weak could not do this, and more readily caught the contagion and succumbed to the disease. The families of the married people among the Artillery suffered severely, and the Maltese suffered much because they were a people living on a low diet. They found that where the air was pure and the apartments large the disease did not stop. In the General Hospital of Valletta only one case arose, although they were constantly introducing the disease. They burnt the bed-clothes, and adopted other measures to stamp it out, and he believed it could be stamped out in these countries, although not in India. The measures which he would venture to suggest ought to be adopted in this or any other country to which the disease was conveyed by ships were, that there should be a port assigned for receiving vessels from all suspected places, and that this port should be under the surveillance of the police, who should be charged with the duty of carrying out the regulations made for the landing of passengers. With regard to the Ionian Islands and Greece, he fully agreed with Sir Dominic Corrigan, that quarantine was not carried out there as it ought to be. But in Malta last year, 1866, quarantine had been properly carried out, and not one case found its way into the Island, notwithstanding that it raged all around and that the embers of cholera remained; for, as he had already stated, in the same house in which an officer's wife had sickened, and her servant had died, a case occurred last year, corresponding in every respect with those cases, except in the immediate danger of death, and some similar cases occurred in Malta in 1866. In India he believed the disease did not require contagion to spread it; here it was different, and we had no excuse for not managing it as the cattle-plague was managed in England, and still more creditably in our own country. (Applause).

Dr. HEAD wished to bring under the notice of the meeting, an instance in which cholera seemed to have been propagated by contagion. On the map before them the town of Portaferry on the north-east coast of Ireland was indicated by a black mark; within three miles of that town there was a little village called Cloughey. No case of cholera occurred nearer to that village than Dundalk, except a few cases that occurred in Belfast, and at the time the disease appeared in the village, there was no case at all in Belfast. There was a fishing-boat which belonged to Cloughey, and which had been fishing off the coast of Dublin, near Skerries or Balbriggan. A boy on board, the son

of the captain of the fishing-boat, took ill; the father would not put him ashore here but sailed to Cloughy, where the boy was put ashore and died; the father took cholera and died, and one of the persons into whose house the boy went also took cholera. There were thirteen cases of cholera altogether in that little village, and eight died. A nurse was sent from Belfast to take charge of the patients, and she took cholera. These cases of cholera occurring in that village were distinctly traced to the fishing-boat. It was difficult to explain the outbreak of cholera in that remote and isolated locality, except on the theory of contagion.

Dr. MAPOTHER said he would not have addressed the meeting except that the explanation of the disease which Pettenköfer had given in 1854, and which had been accepted by the first British and Continental pathologists, was not alluded to by any previous speaker. Personal enquiry in this city, Liverpool, Arklow, and other provincial towns, had convinced him of the truth of this explanation. Three things must concur for the spread of cholera—1st. The importation of the germ. Any one who considered the history of the first Dublin cases, the first Arklow cases (detailed in his "Lectures on Public Health"), or the statement of the Registrar-General and Dr. Burke, that in nearly every one of the thirty districts attacked, the first cases had been in the persons of individuals coming from places where cholera was present, could scarcely doubt the portability of the disease. The progress of the contagion in the persons of the Dutch emigrants to Liverpool, to the steamship *Helvetia*, in which the disease broke out while off Queenstown, the authorities of which, in a barbarous manner, refused all aid; its return to Liverpool, and importation to this country with something like retribution, must be convincing. The second item is residence over ill-drained places. While small-pox is due to a pure contagion, and ague to a miasm, cholera requires both agencies for its production. Pettenköfer cites the following instance in proof:—The ship *Carnatic* lay for many days outside Madras, the sailors being frequently in that town. The soldiers whom she was to convey passed directly through the town, and embarked. In four days all the sailors were attacked with cholera, while not one of the soldiers suffered, although they assiduously nursed the patients. To show the connection between the disease and ill-drained, excrement-soaked places in this city (continued Dr. Mapother) I marked on a large map the houses in which every death by cholera had occurred, and then traced in the streams which, according to Speed's and Rocque's maps, were extant in 1610 and 1756, such as the Tongue, the Bradogue, the Hoha, the City Ditch, &c.; and nearly all the cases corresponded to such obstructed and forgotten streams. The third point is, that some persons are more likely than others to catch and die by the disease; the ill-fed, the drunken, the unwashed, the ill-aired, whose blood is loaded with unhealthy fibrin; infants in whom that material abounds from the absorption of temporary organs, and the old, whose wasting tissues throw it back upon the blood, suffer most, and most fatally, as there is more pabulum for zymosis. Thus I would explain the cases of the wretched Connaught men and the fortunate policemen, so forcibly contrasted by Sir D. Corrigan. I may announce that Mr. Radcliffe's experiments for the Privy Council, just completed, prove that rats and mice take the disease if dosed with choleraic fæces, between three and five days after their ejection. As it has been stated that Indian experience is against contagiousness, I beg to refer to Mr. Orton's work, the fullest and best ever published on the disease, although issued in 1831, and to many of the late reports to the Epidemiological Society. A few words about treatment: While quinine cures ague (which it probably does by supplying a deficiency of quinoidine, a natural component of ours), the search for an antidote to the cholera poison can never be hopeless, and when malaria, which has felled scores of times as many victims as cholera, has been almost banished from these countries, we must always regard the latter pest as exterminable. I gave Calabar bean to patients in cholera collapse, as it is a direct sedative of the sympathetic system,

which, I think, in that pathological state, as well as in the collapse due to a crushed limb, or to fear, is excited. Such is indicated by the dilated pupil and contracted capillaries, which produce the cold surface, the shrivelled fingers, the sunken eyes, and pinched features. Such promising agents as strychnia, warm-water packing, or rolling in cotton-wool, act indirectly as sedatives of the sympathetic. According to the reports, it appears that of eight patients in collapse who took Calabar bean, five recovered, three died—a ratio which acquits my experiment of any homicidal result.

Dr. CRUISE said, as the question of contagion or non-contagion in cholera was immediately before the meeting, he thought it only right, in justice to himself and his colleague Dr. Hayden, with whom he had attended a large number of patients at the Mater Misericordiæ Hospital, to mention some facts which led him to the opinion that cholera was contagious and propagable by contact. It was quite true, if they took individual cases, they were liable to the accusation of arguing a *particulari ad universale*; but, he thought, if they examined all the cases carefully, they would find but few in which they might not trace a fair probability of contagion; in other words, he believed that, in many instances, a belief in non-contagion was due to insufficient information. He was called on in the latter part of October to see a clergyman in Clondalkin. He saw him at four o'clock in the afternoon, he was then collapsed in cholera, and died that night. This clergyman had been called upon the previous night to attend a woman in cholera. He remained with her two hours, returned to bed and fell asleep, awoke ailing in the morning, sickened about eight o'clock, and had such marked symptoms that it was necessary to call in Dr. McCrea of Clondalkin. He pronounced the case to be one of cholera, and prescribed accordingly. The woman's history was as follows:—she had a brother living at Kingstown, who had been seized with cholera and died there. She went to Kingstown to attend the wake, remained there three days, returned to Clondalkin, took cholera on that day, and died on the day following. It might be chance that caused this woman to take cholera, and chance that caused the clergyman who attended her to take cholera also, but the coincidence was, at least, very remarkable. A young woman was admitted to the Mater Misericordiæ Hospital with her child labouring under cholera. The woman recovered, the child died. What was the history of this case? The young woman lived in the county of Kildare. She had a single child which she placed at nurse in Cork-street. She heard that the nurse, with whom she had placed the child, was ill, and came up to town to see after the baby. She found the woman ill of cholera. She removed the child to a street off Marlborough-street, where they both took cholera, and were sent a few days after to the Mater Misericordiæ Hospital. He admitted that this might be all chance, but it was possible to entertain an opposite opinion. Several gentlemen, who had had large experience in India, said that cholera was not contagious. To their opinion the utmost respect was due, because their opportunities of observing cholera were much larger than we possessed in this country. Nevertheless, it was right to state, that opinions differed with regard to cholera in India. When attending cholera cases last year in the Mater Misericordiæ Hospital he met a fellow student of his own, now a distinguished surgeon in the Indian army. He asked him what was his experience of the disease in India, and he replied that it was looked on as decidedly contagious; that there was the utmost reluctance on the part of the men to attend on the cholera patients, and that there was almost a mutiny in his regiment from the enforced attendance on the sick. He said also that a large proportion of the men who discharged this duty took cholera, but not one of the officers was affected. A large number of medical students, who displayed so much earnestness and zeal during the epidemic in France, were seized with cholera, and died of it. Referring to the registry of the cases treated in the Mater Misericordiæ Hospital it would be found that a large proportion of the cases came from houses in which cholera was raging. For instance,

a case would come in from Greek-street, and it would be followed within two, three, or four days by others coming from the same house; this might be only chance, but it was only fair to admit that it was not altogether unreasonable to entertain an opposite view. For his part he quite agreed with Sir Dominic Corrigan, that the degree of contagion in cholera was not comparable to that of typhus or scarlatina. But the question of degree was not in point as regarded the question of contagion itself. The fact that cholera had arisen where there was no way of accounting for it by contact was no proof of its non-contagious nature; for he had seen cases of typhus and scarlatina arise under similar circumstances. Neither would he admit that the non-spreading of the disease was a proof of the non-contagion theory. In the Mater Misericordiae Hospital not a single case arose from spreading within the walls of the institution; but, it was right to state, that the hygienic measures adopted there were extreme. He might quote the statement of Dr. Stokes in reference to typhus, that there had not been one case of the spreading of that disease from the fever wards of the Meath Hospital to the cholera wards. An instance occurred under his own observation, where a child was sucking when the nurse was labouring under malignant typhus, yet the child never showed a symptom of the disease; no one, for this reason, would venture to say that typhus was not highly contagious. In his opinion, if they carefully investigated all the cases of cholera they would find sufficient reason to believe that it was propagable by contagion, although not nearly so virulent as typhus, small-pox, or scarlatina.

Dr. MORROGH, H.M. Madras Army, said that he had served twenty-two years in India, and had had much experience of cholera, and that he never saw a European or a native soldier hesitate one instant to attend to his comrade who was stricken down with the disease. He made it a rule to ascertain whether the soldiers called on to discharge that duty had any fear or timidity with regard to the disease, and he had never met with an instance of the kind. His experience of twenty-two years in India had taught him that cholera was not in any way propagated by contagion. He had seen thousands of cases of cholera; he had attended it in the camp and in the field, and he had the disease very severely himself; but he did not get it from communication with the sick. He got it at a time when there was not a single case of cholera within 100 miles of where he was stationed, and he attributed it to having drunk three or four glasses of sour claret (laughter). He had been exposed to contagion as much as any man could have been, but he did not take the disease in that way. He remembered two of his apothecaries being struck down. One of them was a very timid lad, very nervous and apprehensive of the disease; he was very zealous, exerted himself too much, and became greatly debilitated, and sunk under the attack. The other recovered. He thought all the medical men of experience in India would coincide with him that cholera was not contagious. Previous to his going to India he had experience in cholera. In 1832, when the epidemic was in Edinburgh, he was a volunteer in the hospitals there. After taking his degree he was employed under the Cholera Board in this country, and attended cholera in the counties of Waterford and Cork. He went to India a confirmed contagionist if ever there was one, but in that country he saw no preparations for a contagious disease. Every man who was attacked was at once sent into hospital, just as if he had a broken leg, and the disease was never communicated from bed to bed. It took him some four or five years before he got rid of the idea that cholera was contagious. As to the young gentleman from whom Dr. Cruise derived his information, he was probably ignorant of the Indian language, and did not know what the natives said to him. The native soldiers were most affectionate to their comrades. He never saw a native soldier refuse to attend his fellow-soldier; in fact, there was a religious feeling among them on the subject which would render the thing impossible.

Rev. Professor HAUGHTON said his friend Sir Dominic Corrigan had done him the justice to say that he was willing

to die in the cause of cholera, but he seemed rather to complain that he did not die (laughter). Now, whatever little service he might have rendered in the cholera epidemic, he did with the full resolution under no circumstances to die (laughter). But, at the same time, he was willing to confess that if he had ten lives or twenty lives he would gladly lay them down to help the poor. He would say in the words, not of a christian, but of a pagan—*Homo sum, humani nihil a me alienum puto* (applause). He should be sorry to deprive the friends and relations of the good priest described by Dr. Cruise of the mournful consolation that he died as a good clergyman should, with his eyes open to the danger he incurred, and in the brave discharge of his duty. He was free to confess that the production of the map now before them was due to the suggestion of his friend Sir D. Corrigan. On the former occasion, to which allusion had been made, he was greatly struck with Sir Dominic's cholera map; it seemed to him a most valuable contribution to the cholera epidemic in 1849; it contained a valuable record of the towns that were attacked by cholera and that escaped it, but it was not accompanied with any explanation as to how a certain set of towns acquired the cholera, and how another set of towns was exempted from it. In the pamphlet which accompanied the map Sir Dominic Corrigan threw out a suggestion as to the reason why the eastern towns were exempted from the disease, while the western towns were subject to it. This was a mere guess, and as he (Professor Haughton) was equally entitled to make a guess, he ventured upon one, and the unfortunate reapers came into his head. He wanted to supply, if possible, a clue to Sir Dominic Corrigan's map. He presumed now from what they had heard that evening, that the poor reapers were blamed unjustly, and that they did not carry the cholera from England to Connaught. But he thought Sir Dominic Corrigan's map was no longer a puzzle. He ventured to say that the map he had constructed of the cholera epidemic of 1866, gave the key to the older map of 1849, which would prove of the greatest possible value to medical science. He started with a general feeling in favour of the contact theory, but with a determination not to allow himself to be influenced by that view in opposition to facts. The result of his inquiries had been the map before them, and he had evidence to show that nearly every town which was marked in black as having been visited with cholera, had derived it either directly or indirectly from the town of Liverpool, and there were only a few towns on the map—Parsonstown for example, which derived it from Sheffield and Westport, to which the contagion was carried by sea from South Wales—which were not indebted to Liverpool for the disease. Cholera entered Ireland at four points by sea: Belfast, Dundalk, Drogheda, and Dublin. Dr. Head had stated the remarkable circumstances connected with the outbreak of the disease in the little village of Killougher in the North. Other towns derived the cholera from Dublin, which was a secondary or indirect importation from Liverpool. He had marked the lines of railway along which the epidemic travelled, and had divided the towns into groups according to the time at which they were attacked. Thus, Dublin was No. 1, Belfast 2, and so on. The disease did not travel in a direct line, as it would if it were conveyed by the atmosphere, but jumped from place to place as it would if conveyed by personal influence. The reason why Mallow suffered before Newbridge, was that the cholera patient who brought the disease to Mallow, took a ticket for Mallow and not for Newbridge. If he stopped at Mountmellick he would have brought the disease there, or if he went to Kilcock he might have introduced it into that dirty village, and killed the Kilcockians (laughter). The comparative exemption of Ulster, and the apparently sporadic spread of the disease into the west of Ireland, were apparent on his map as well as in the map of 1849; the resemblance between the two maps was great, and the same facts were disclosed by both. He gave his friend Sir Dominic Corrigan credit for more than his usual skill in finding an explanation for the facts. The reason why Sir Dominic thought Ulster was exempted

from the disease was, because the people of Ulster are more prosperous, more active in their commercial enterprise, and therefore must be supposed to have more intercourse with each other than the people of other parts of Ireland. Every one who knew intimately the self-reliant people of Ulster knew that the contrary was the fact. Ulster consisted of a series of isolated centres of enterprise. Each man in that centre considered himself superior to every one in any other part of the earth; he held little intercourse with others, and as to the *Times* he did not believe in it, and it was to be wished that other people in Ireland would follow his example in this respect (laughter). Places like Enniskillen, Strabane, Dungannon, and Omagh were, as he had said, isolated centres of industry; they had little or no intercourse with Liverpool, they did not go there, they did not care about it, and therefore the same broad fact appeared on his map which was exhibited by the map of Sir Dominic Corrigan—the exemption of these local centres of industry in the North from the disease. As to the spread of the disease into the West, he had got information with respect to its importation into Westport, Ballinasloe, and Kilrush. Dr. Croker King gave him the names of the persons who brought it to those places. In fact, all those cases which would otherwise be regarded as due to sporadic or epidemic influence were explained the moment they obtained the history of the individual cases. He thought this discussion, which had the result of showing that there was less difference of opinion between them than when they commenced, could lead to no more interesting or important result than a demand upon the poor-law authorities to inform them in detail of the opinion of the Medical Officers employed under them in each town and district, as to how and when the cholera was introduced into their respective districts. Cholera and the introduction of cholera, like every other matter of science, must be subject to the rules of severe logic, and as several of the observations made that evening exhibited very lax views on this important subject, perhaps they would allow him to state what he believed to be the correct view of the contact theory of cholera. The contact theory of cholera was based on two hypotheses. The first was one they were all familiar with, there must be, *ab extra*, a materies morbi. For the second term he would propose a new form of expression. Receptivity was *bog latin*, but he had found an expression in the works of the elder Pliny, who lost his life, in the pursuit of science, at the destruction of Herculaneum, which he thought would be appropriate. Pliny, speaking of a friend, described him as *capax secreti*—one who could hold a secret if you put it into him, and he carefully excluded his wife from that category (laughter). Now he would propose the term *capax morbi*, which means the capacity of receiving the disease, and the capability of holding it when you got it, as the second hypothesis on which the contact theory depended. If they accepted those two hypotheses, they easily disposed of two classes of fallacies—fallacies of which he believed he had heard a great deal that night. First, the occurrence of cases in which persons were in contact with cholera who did not take the disease. He envied them their luck, they must be very tough and have magnificent constitutions, and their friend, the army surgeon, who had described his views on the subject so clearly might be perfectly certain that he was not capable of taking the disease, while more delicate persons were. The secretions of the skin in tropical climates might also have some influence in preventing contact being so dangerous in India as it would be in a colder climate. The second class of cases were those in which genuine cholera occurred in persons who were not in contact with the disease. This was illustrated by the outbreak in Mountjoy Prison, but he was sure his friend Dr. McDonnell would not press that beyond its legitimate consequence, which was to show how difficult it was to ascertain exactly the origin of the disease in every case. Here they must confess their ignorance, but he would not confess ignorance in general. The contact theory, he submitted, was much more probable than any other that had been advanced. But on two points they

were ignorant—they were ignorant of the precise nature of the materies morbi, and of the precise quality of body that constituted the *capacitas morbi* in the subject. He trusted one important result of their debate would be that in future they would direct their attention in a more precise manner to trace the particular channel by which the disease entered the body, and the particular condition of malaise or ill health, which rendered an individual susceptible of it (applause).

Dr. WHITE said, as one of the medical officers practising in a district in which a great deal of cholera appeared last autumn, he wished to say a few words on the subject. The first case of cholera which occurred at that side of the county of Dublin came under his notice. It was that of a lady whom he attended in her confinement, and he could not say from what he had heard that evening but that he had himself been the means of communicating the disease. He was attending at the Meath Hospital, watching the progress of cholera, the very day on the night of which he was called on to attend this lady. On the fifth day after her confinement she was attacked with cholera, passed through the disease and recovered; on the sixth day of her illness the nurse-tender was attacked at half-past two in the morning, having gone to bed well on the previous night. This woman died. The other attendants in the house were very careful as to cleanliness. As to the nurse there was probably the *capacity* in her system, for the woman was a drunkard, and had been indulging largely in spirits when in attendance on the lady. The next case which came under his observation was that of a gentleman who lived in a large, well-situated country house; he had been in Dublin during the day. He was attacked with cholera at night, passed through the disease well, and immediately on his convalescence, his wife, who had been in close attendance on him, was also attacked with cholera. On the third occasion, he was called in to see a servant in one of the best houses in Rathgar. There was nothing to account for her illness that he could find out, except the one fact, that she had been at a party at Donnybrook, where cholera was prevalent, and the night following she was in cholera. An infant was in bed with her when the first indications of disease appeared. A few hours after being removed, the infant presented all the symptoms of Asiatic cholera, passed through it, and recovered. The woman died. With respect to the immunity of the police from the disease, he should say that, in his district, the police did not come into contact with the cholera patients, for they performed no sanitary duties. Two policemen in Crumlin were attacked, and attended by Dr. Davy. The first man recovered; the second, who slept in the same barrack-room, and was in attendance on his comrade, received the disease, and, he regretted to say, succumbed. There was another man who acted as nurse-tender, he never showed the least sign of illness.

Dr. CHARLES F. MOORE said—As no other City District Medical Officer had addressed the Society, he was desirous of mentioning the course cholera appeared to take in No. 3 Dispensary District. 190 cases of cholera, and considerably more than 1000 of diarrhoea, came under the notice of the medical staff of that district. The first case of cholera was that of a labourer, who worked near the quays, where the cholera first appeared in this epidemic, but who resided in Bride-street; subsequent cases occurred in over-crowded and otherwise unwholesome cellars and other tenements. One of the worst outbreaks took place in a house inhabited by the lowest class of prostitutes, and spread thence to the adjoining houses, which, after much trouble, the medical officers succeeded in getting closed. From three or four centres the epidemic radiated to the other parts of the district. In 1854 he was one of the physicians of the Finglas Cholera Hospital; the epidemic, on that occasion, commenced in a man just arrived from Belfast, who, after eating to excess and drinking much porter, was seized with the disease; he recovered; but a girl, living in the same very unwholesome house as this man, took the disease, and died of it, and at her wake several persons sickened, and thus the disease rapidly spread through the village, and

many persons fleeing thence carried cholera to Kill of the Grange, the North Dublin Union Workhouse, and in other directions. His (Dr. Moore's) previous experience in Southampton, Egypt, the Mediterranean, &c., also had led him to consider that the disease spreads from person to person. The last Army Medical Report, that published in 1866, contained much evidence to show that the disease was communicated from those already sick, or in contact with the sick, to the healthy; the very striking instance of the last epidemic in Gozo afforded evidence on this point. That island was remarkably secluded; the disease spread from a sailor who returned to his native island from Malta with the cholera upon him—first, to his own family and friends who had nursed him in the disease, and by those persons the illness was carried to the hospital in Rabbato, the chief town of the island, whence it spread to the general population. Dr. Gordon's work on "Hygiene," published in Calcutta in 1866, recognised the spreading of cholera by contagion in numerous instances where pilgrims passed near bodies of troops, &c. He would only add, in conclusion, that the experience of the past as well as of previous epidemics in Malta, and what he himself had observed at home and abroad, led him to believe that human intercourse was the chief element in the spread of the disease.

Dr. LAING, Staff Surgeon-Major, said—A gentleman remarked on the previous night that he never heard of the epidemic influence of cholera travelling faster than man could do, but he (Dr. Laing) did not think it could travel nearly as fast. Any one who ever observed in the country the smoke from a fire, must have seen how every little inequality, every bush and tree stopped it, and prevented it from travelling quickly; and he was of opinion that rivers were quick channels for the conveyance of epidemic influences—not from their having "traffic" on them, and being, therefore, a means of human progress—but because the smooth surface of the river offered less impediment to the travelling of the epidemic influence along it. He was frequently in the swamps of America, and observed that the people who lived on hard ground in the middle of these swamps were perfectly free from attacks of intermittent fever, whereas those on the border portions of the clearing, where the original forests remained, were subject to severe and prolonged attacks of intermittent fever, showing the appearance of it in their countenance, and in an enlargement of the spleen. He was in Prescott, on the banks of the St. Lawrence, when cholera came to Quebec—how or when he could not say. It came, he believed, when the emigrants landed at Quebec, and they heard of it appearing at various towns on the St. Lawrence. Every morning he went down to the wharf where the steamers touched, to hear anything about it that was to be learned. A poor German emigrant woman who had the disease was landed at the wharf. She was put into a shed, and the most effectual quarantine surrounded her, for no one went near her but her husband and himself (Dr. Laing), and he fed her and brought her the food with his own hands. The disease broke out in Prescott, and spread round the town. In one place there was a small two-storied house of wood. It was surrounded by poplar trees, standing so closely and thickly together that they prevented the light getting into the windows. This house was exposed to a breeze coming across part of a river which had been embanked for the purposes of the railway. The breeze blew directly on the house, and in that house he attended eight cases of cholera, all of which died. He attributed this to the cholera malaria coming up and across the river, and being collected and kept round the house by the trees. He thought this showed that in most cases sanitary reform was the great thing to be attended to. He might observe in reference to a statement which had been made by one of the speakers that evening, that he had lived a good deal of his life in India, and had been attached to English and Irish regiments, and he never yet saw a British soldier refuse to attend his comrade in sickness. If he held up his hand he would have a hundred volunteers for the duty. If the Medical Officer who said he found reluctance on the part of the soldiers to

attend their comrades belonged to the regiment, he and other officers must have shown a bad example. It was the officers who were really answerable for the conduct of the men.

The PRESIDENT said it now became his duty, as their chairman, to make a short summary of the proceedings of the last three nights. In the first instance, they had reports from the various Dublin Hospitals that had opened their doors to receive cholera patients—the Meath, Hardwicke, Sir Patrick Dun's, and the Mater Misericordiæ Hospital, and also one from the Mountjoy Prison. In addition to these they had a most valuable abstract of a report of a recent epidemic at Utrecht, which they owed to the kindness of Dr. William Daniel Moore, and they had a report from the Bray Hospital by Dr. Darby. Now the debate of the two last nights could hardly be considered to have been on those reports. It took a wider range, and he thought none of them could regret it, inasmuch as it had brought out a great store of interesting information from the army medical officers, for which they all felt deeply indebted. The results of the reports might be considered in a three-fold point of view. First, as to what additions the experience of the late epidemic had made with reference to the pathology of the disease. Next as to its treatment; and, third, the question of its communicability or its mode of outbreak. Several dissections of cholera patients were recorded. Dissections had been made at the Meath, Hardwicke, Mater Misericordiæ, and Sir Patrick Dun's Hospitals. Nothing of importance had been realized, and this was what they should expect; for cholera, which, as they would all admit, was in the category of essential diseases, was not an affection that would shew appreciable anatomical changes. Anatomy told them what it was not, not what it was; its information was negative, and there was one reason for this besides others—namely, the short course which the disease runs, so that there is not even time for the formation of those secondary organic affections which so commonly arise in essential diseases. Certain changes had been found, but they were quite incompetent to explain the nature of the disease, they were inconstant and unnecessary. The blood had been found thick and tarry, and the rigor mortis well marked. The rise of the temperature after death was a very curious circumstance that had been recorded in the Hardwicke and in the Mater Misericordiæ Hospitals. In this respect there was a curious analogy between cholera and sunstroke; the rise of temperature in the latter had been recorded by many military officers; it might rise three degrees beyond what it was at the time of death. He might be excused for alluding to another analogy, which would go for as much as it was worth. Last year, in the *Dublin Quarterly Journal*, there was a paper on sunstroke by a pupil of his own, Dr. Baxter, and he held that there was a very great analogy indeed between many of the phenomena of sunstroke and the phenomena of malignant or spasmodic cholera. Another remarkable fact had been observed—viz., that the extreme lividity of the body before death disappeared very much after death. Something very similar had been observed in cases of the disease called by some, "Purpura Maligna," and the "Black Death," where the large petechial or ecchymosed spots, almost black at the time of death, became red on exposure to the air. The right chamber of the heart was found full of blood, and a coagulum was formed in the pulmonary artery. Dr. Kennedy had alluded to puerile respiration arising from weakness of the heart as a symptom threatening death. This was very important, it showed a great analogy to other cases of weakness of the heart, for one of the most remarkable signs of fatty degeneration of the right side of the heart was the existence of loud puerile respiration, either constant or occurring in fits. The brain had been found generally healthy, and the spinal-marrow also. There was nothing else remarkable but a washed appearance of the intestines, and, in some instances, the bursting of Peyer's and Brunner's glands. The next thing to be observed was cadaveric twitchings. This was an extraordinary phenomenon. He

was acquainted some years ago with Staff-Surgeon Marshall, an old Indian officer, who stated that in the early outbreak of cholera they were all anxious to determine the nature of the disease by post-mortem examinations; but he found it difficult to go on with the dissection, for the moment the incision was made in the sternum the body would spring up with frightful gestures, as if galvanized, and it was very hard, he said, "to make the young hands go on." As to treatment no cure had been discovered for cholera, and no cure, no specific was sought for. In this respect cholera was not peculiar. There was no cure for any essential disease. No man could venture to say that this or that treatment will cure an essential fever. The physician guides it to recovery. He knows the system is exposed to two dangers—debility and secondary disease, and steering between these two rocks, he guides it until the time when the clock strikes and the disease ends of itself, either in death or recovery. So it was with cholera. In the reports from some of the Hospitals, there were columns apparently recording the results of special treatment, and this was objectionable, for it led to misconception as to the practice of the Hospital. They read of so many cases treated by calomel, so many by white of eggs, so many by stimulants, and so forth. The objection to such a column as this was, that it might lead the public or medical men at a distance to the erroneous impression that in the Dublin Hospitals there had been any cases treated by this thing or that thing alone. The great characteristic of Irish medicine, as Sir Dominic Corrigan had said, was its eclecticism; and when they inquired into the treatment of cholera patients, they found that it had been decidedly eclectic, and no one mode of treatment had been adopted in any number of cases. But with respect to palliative treatment something might be said. It had been found in some of our Hospitals that an admirable method of relieving painful spasms was by the inhalation of chloroform. This might be done with perfect safety, and repeated again and again—not to such a degree as to produce insensibility, but to act as an anæsthetic and procure the patient relief. So, also, they found in the Meath Hospital great value, in the collapse, from Sir D. Corrigan's button cautery along the spine. In cases of suppression of urine, even when uræmic symptoms had appeared with complete suppression for forty-eight hours, cupping repeated again and again, drawing a few ounces of blood, had restored the secretion of urine, and been attended with success. The treatment by saline injections had been tried by him, and with the usual result of apparent and almost instantaneous relief, but in the course of a few hours purging came on again, and the case was as bad as ever. In the Mater Misericordiæ and the Meath Hospitals the treatment by calomel was tried, and with some fortunate results. It was found that when bilious stools were produced, the patient's chances of recovery were greatly increased. Now, as regards the question of contagion, Dr. Kennedy spoke of negative evidence, by which he meant the general opinion among gentlemen who practised in India, against the doctrine of contagion. It would be quite wrong to shut their ears to the evidence of these gentlemen. It was extremely important, however, on the other hand, that they should remember they were not to infer the phenomena of disease in one part of the world from those in another. The question of contagion in the North—in European countries—had some elements of difference from the question of contagion in tropical climates. The principal mortality in India occurred among the natives, and here we got another element—the comparative mortality of the disease in coloured men and in white men. It might be that the natives of the tropical climates and the coloured races generally were more liable to the exciting causes of cholera than the whites. He thought that extremely probable, and it also might be that contagion was apt to be more rife in the colder than in the warmer climates. It might be said, also, that the European constitution was less liable to contagion in India than in a more northern climate. So far as he could collect from Dr. Mackesy, who had had great experience, that was his opinion. Dr. Lyons, who advocated the non-contagion

theory, had dwelt on the fact of the immunity of a large proportion of the staff of the Hardwicke Hospital. A similar circumstance was observed in the Mater Misericordiæ Hospital, where there was a large staff of Physicians, and of Sisters of Mercy and hospital nurses, in constant attendance on patients, and yet there was not a single case of contagion. This showed, in a striking manner, that the disease during the late epidemic was not eminently contagious. But when they recollected the epidemic of 1849, and recalled to mind the terrible mortality among medical officers who were sent down to the country—five medical men, for instance, having been struck down in Sligo—they had a set-off against the immunity of Dublin during the late epidemic. The outbreak in Mountjoy prison might be set against the contagion theory, and seemed to point to the spontaneous origin of cholera. But it was to be remembered that at the time of this outbreak there was a general epidemic prevalent, and they had to balance the chances of some communication from without, with those of the spontaneous generation of the disease within. It was remarkable that, coincident with the outbreak of malignant cholera in the Prison, there was a great number of cases of choleraic diarrhœa, and this furnished them with arguments for the philosophic view put forward by Dr. Darby—that when there was an epidemic of cholera, all those cases of diarrhœa which were apt to run into cholera must be considered a species of cholera of a mild form. If this be so, and he had no doubt of it, it would greatly diminish the percentage of mortality, which, in place of being 50, would be only 20 or 30 per cent. The proofs of contagion in any epidemic mainly depend on a balance of probabilities, and the application of the doctrine of chances might be well made to clear up the matter. This was done in reference to fever by the late Dr. Whitley Stokes, who proposed certain problems to the Bishop of Cloyne, who was well skilled in the calculation of chances, as to the probabilities for and against the occurrence of ascertained events, assuming that the illness of one person did not promote that of another. The Society will find the results in Dr. Stokes' observations on Contagion. This mode of proceeding was eminently deserving of the attention of the Society. Dr. Stokes concluded by congratulating the Society on the three meetings, and thought that great good would come of the discussion which had taken place.

On the motion of Sir D. CORRIGAN, seconded by Rev. Professor HAUGHTON, a vote of thanks was passed to the Military Medical Officers, for the information which they had given to the meeting.

The meeting then separated.

## HARVEIAN SOCIETY OF LONDON.

MARCH 21st.

President—Dr. J. E. POLLOCK.

Mr. ISAAC BROWN read a paper on

ANÆSTHETICS IN MIDWIFERY.

Commencing by paying a tribute of praise to Sir James Simpson, and all those who, through much labour, opposition and obloquy, had succeeded in bringing the induction of anæsthesia to perfection, Mr. Brown felt that we were bound to relieve, by the same means, that pain of which, as practitioners of medicine, we all so constantly witness—the great pain and travail of labour. He reviewed the principal objections, scriptural and professional, which had been raised against administering anæsthetics in midwifery, and showed how completely they had been answered by Sir James Simpson, and also by Dr. Protheroe Smith. Although one seldom now hears, in their former intensity, any of the original unwarrantable objections, there are not wanting, says Mr. Brown, some who do object to chloroform or any other anæsthetic in midwifery, on the ground that by such means the strength of the uterine contractions is impaired, and that there is not sufficient risk to life, arising from the pains of labour, to justify us in adminis-

tering for their relief an agent, itself capable of risking life. The first objection he hoped to prove untenable, by relating cases which would show labour to be rather hastened than impaired by anaesthetics, and to the second he would give the best answer, by bringing under notice an anaesthetic agent, which is, under ordinary circumstances, incapable of producing total unconsciousness, and so reducing the risk of loss of life from its influence to almost nil.

Ether, the first anaesthetic introduced to the profession, Mr. Brown considered entirely unsuited for midwifery purposes, from the large quantity required, and consequently its expense and unportability, and also on account of its disagreeable odour.

Chloroform, *pur et simple*, he also objected to as liable to be given to the induction of full narcosis, although he admitted, with Dr. Rigby, that "in almost all private patients you can draw the line between loss of pain and loss of consciousness." It is this word "almost" that makes a dilution of chloroform necessary, for the practitioner ought not, in administering an anaesthetic to a parturient patient, use an agent which compels him to give a divided attention to that office for which he is especially called—viz., aiding the birth of the child.

Mr. Brown objected to the mixtures recommended by the Chloroform Committee of the Medico-Chirurgical Society, on the ground of the ether that they contained, and quoted largely from Dr. Sanson (without doubt next to Dr. Snow, the English physician, to whom we owe most for really valuable investigations on the subject) to show that in alcohol alone we have an agent on which we can fully rely as a diluent of chloroform, and he also used the same gentleman's arguments, and repeated the objections which he had himself made in answer to Mr. Ellis' ingenious but exceedingly complicated and unnecessary method of inducing anaesthesia by mixed vapours. With reference to Dr. Townley's "anodyne mixture," Mr. Brown had been compelled, as had also friends of his, to abandon it as he did not find it, when made up by others than Dr. Townley's own chemist, so efficacious as from his book one was led to hope.

Moreover, the aromatic tincture added by Dr. Townley, had, as it evaporated, a most disagreeable and drug-like smell.

Mr. Brown, in March, 1865, had made some experiments with dilutions of chloroform with alcohol, and had found that the most convenient for use in midwifery was two parts of chloroform with one of alcohol. In the latter was distilled the essential oils used in the preparation of eau-de-cologne. The mixture was clear, and as it evaporated, very elegant and agreeable to the patient. If properly prepared it should have a specific gravity of 1.152. It must not be confounded with a mixture of chloroform and ordinary eau-de-cologne, in which there being water, the chloroform is at once precipitated. Mr. Brown did not consider there was any particular merit in the eau-de-cologne besides its agreeable odour, but suggested it might help as a gentle stimulant, in combination with the alcoholic dilution, to prevent the patient from being fully narcotized.

This mixture to which he had given the name of chloro-etherine, it being, as it were, a concentrated chloric ether, had been exhibited at the Obstetrical Society, October, 1865, and had since been used largely by him in his own practice, and also by many others. He did not himself use inhalers, but they who did could administer his mixture in them as well as chloroform. For all practical purposes he considered that for a dilution of chloroform, a napkin, folded cone-shape, was most convenient. There were no particular directions with reference to its administration. It should not be given until the os is well dilated, except in cases of rigidity of the os, when a few inhalations will speedily produce relaxation; nor should it be given after the child is born, although patients may often ask for it, so severe do they find the pains accompanying the birth of the placenta, after having been delivered of the child without pain.

Mr. Brown concluded by relating cases which had

occurred in his own practice, and two in which he had administered it for Mr. Philip Harper, and for Dr. Abud. He also read letters from Dr. Sanson, and from Mr. Roberts, Honorary Surgeon to the Hull Lying-in Infirmary, supporting him in his belief that in chloro-etherine we have as simple, efficacious, safe, and agreeable a method of relieving "the pleasing punishment which woman is born to bear" as is yet known to the profession.

Dr. CHAPMAN thought that the first action of chloroform was on the capillaries, and not as generally supposed, on the heart. Dr. Snow thought death ensued from paralysis of the heart; but it must be remembered that the great force moving the heart resided in the capillaries. Deaths are brought on, he believed, by congestion of the portal system. He performed some experiments by chloroforming animals, and afterwards dividing the portal vessels; although the heart had ceased to beat it resumed its pulsation when the portal vessels were divided and the right side of the heart emptied.

Dr. C. DRYSDALE had in former years, when assistant-obstetrician in a hospital, been in the habit of administering chloroform in all cases of midwifery. He thought that when only administered to allay the pain in healthy persons, and with plenty of air, as when Skinner's web was used, there was no danger, and he thought it was rather a want of humanity to allow so much suffering as usually took place in parturition, without using so simple a remedy.

Mr. CURGENVEN said that chloroform was rarely used in obstetric practice in London, he seldom used it himself. In 1851 he had given it to a lady; but she became blue in the face, and this had given him a dislike to it.

Dr. HOLT DUNN said that the danger in administering chloroform in midwifery was very slight; but still it existed. He had never seen any bad consequences from administering it in such cases, and it was remarkable that there was not the sickness observed in such cases which was seen in operative cases.

Dr. ROYSTON said he had been long averse to chloroform in midwifery, and had very rarely used it.

Mr. OWEN said that in many cases it had seemed to him that the air did not pass well through the aperture in the cone recommended by Mr. Brown. Dr. Lockyer's opinion had been, that the simplest method of administering chloroform to women in labour was to put  $\frac{1}{2}$  in the bottom of a tumbler on some cotton-wool and let it be smelt.

Mr. WALKER said that this was a capital suggestion. Skinner's web, referred to by Dr. Drysdale, was as good and as safe an apparatus as could be devised, and the nurse could be quite well trusted to drop a few minims occasionally on the web without any danger of doing harm. Women in labour took chloroform very well.

Dr. CAMPS thought that the giving of chloroform was always attended with a certain amount of danger. Deaths occasionally would take place, spite of every precaution. He believed the immediate cause was often paralysis of the pneumogastric nerves.

Mr. PARKER YOUNG asked Mr. B. Brown whether his mixture was as rapid a relief from pain as chloroform was. He had found, on using chloroform in labour, that a very considerable quantity of it was required to produce anaesthesia in a long labour, and it was therefore very expensive.

Mr. ISAAC BROWN said that he had on no occasion required to use more than one fluid ounce of his mixture in one case.

#### THE PULSE.

A LECTURE, supplementary to the ordinary courses, of which we have already published abstracts, was this year delivered at the London College of Physicians, by Dr. Burdon-Sanderson, who has paid much attention to the sphygmograph, and which illustrated in various ways the use of that instrument. The lecture was entitled "On the Mode and Duration of the Contraction of the Heart in Health

and Disease," and its chief object was to show the relations of the cardiac movements to the pulse. It was illustrated by a number of tracings from the sphygmograph on glass, illuminated by the oxycalcium light.

Dr. Sanderson considered that every pulsation is composed, so to speak, of four separate actions, viz. :—(a.) The sudden or primary expansion of the artery. This, he believes, does not arise from an increase of the quantity of blood in the artery, but rather from the sudden shock resulting from the forcing forwards of the particles of the liquid by those behind them. (b.) Gradual distension of the artery. The degree of fullness and the time required to effect it depend on the quantity of blood transmitted to the artery by the contraction of the ventricle. (c.) Collapse of the arterial wall. This the lecturer considered to depend on the impulse of the particles of the liquid in the arteries towards the heart, and the effect, therefore, is due to the velocity of the movement rather than to the extent. (d.) Diastolic expansion of the artery. This is the second beat which, when preternaturally distinct, is called *dicrotism*. This phenomenon, which has given rise to much conjecture, is considered by Dr. Sanderson to depend on the distension of the arterial walls, aided by the pressure of the blood, both these being produced by the forcing of the blood into the artery during the heart's systole. The distension he considered to bear a *direct* proportion to the elasticity of the artery, while the ratio of the pressure against the internal surface would be in an *inverse* proportion. Thus, the more elastic the artery the greater the increase in the area of the pulse and the less the increase of the pressure. So, according to the predominance of one or other state, the collapse of the artery after the systole is complete, no reaction being detected; or, in the opposite case, there is *dicrotism*. The normal state is the balance of the one by the other, and in health, so far as the artery is concerned, the heart employs only part of its force in carrying on the circulation during the systole, the remainder being required to keep up the blood-flow during the heart's repose.

According to this idea the varieties of the pulse in disease may be arranged in two classes :

I. Those in which the tension during systole being diminished, there is less resistance, and the duration of the systole is shorter than otherwise. This may arise from less blood being driven forwards at each stroke, as in valvular disease; or from the heart contracting too soon, as from the effect of stimulants. This constitutes the nervous pulse.

II. Pulses in which the pressure during the systole is too great, and in which there is increased arterial resistance. Of these there are three varieties, viz.—1. The hypodynamic pulse, in which the arterial system is over-distended during the heart's contraction. This may arise from structural changes in the arteries or the capillaries producing increased resistance. 2. The senile pulse. This differs from the other in the absence of diastolic reaction. It is the pulse of an artery that has lost its natural elasticity.

III. The adynamic pulse, well seen in continued fever. In this pulse the result arises from the weakness of the heart rather than from the extent of the resistance. The elasticity of the arteries is excessive, partly from their being unusually empty. The consequence of this is that the reaction is much more sensible, and in a well-marked case we get the distinct double beat of *dicrotism*.

Of these varieties of the pulse, the lecturer seemed to attach much, the most, importance to the first. He submitted that it offers us the earliest indications of structural changes in the arteries and capillaries, and consequently bears directly on the expectation of life, as well as on prognosis.

The lecture was listened to with great attention, and much interest was expressed in the sphygmographic tracings, and the mode of illuminating them. It furnished a very worthy supplement to the Gulstonian, Croonian, and Lumleian Lectures; and concluded a lecture season at the College in which a more than ordinary interest seems to have been taken, and which we have therefore reported as fully as possible.

## Reviews.

THE SANITARY ACT, 1836, with Notes, Statutes, &c. By R. C. AUSTIN, Barrister; together with Commentaries on Public Health and the Sanitary Laws of England, by W. HARDWICKE, M.D., &c. London: Nicholls.

The combination of a legal and a medical authority in the production of this work would naturally lead us to form a high opinion of it, and, after a careful perusal, we have been in no way disappointed. The publication deserved, and would have received, notice in our columns long since, save for the indisposition of the reviewer to whom it was entrusted. Now that a reconstruction and consolidation of the Sanitary Acts has been promised by the Duke of Marlborough, the President of Council, and the Vice-President, Lord Robert Montague, who for so many years has interested himself in sanitary legislation, the publication is most seasonable and useful. The clauses of the various sanitary acts are very conveniently arranged, so that a fair basis for their codification is established. In the latter part of the work, such subjects as medical officers of health, water supply, drainage, cemeteries, overcrowding, noxious trades, &c., are ably treated by the author, and further illustrated by extracts from the reports of Simon, Lankester, Letheby, Mapother, French, and other writers on hygiene. On the whole the work is well-arranged and reliable, and will be most useful to every one engaged in the administration of the Sanitary Act of last year.

QUAIN'S ELEMENTS OF ANATOMY. Seventh Edition. By W. SHARPEY, M.D., F.R.S.; A. THOMSON, M.D., F.R.S.; and J. CLELLAND, M.D. Pp. 1147. London: J. Walton.

THIS standard work is so generally known and so highly prized, that it is only necessary for us to record the additions and improvements which have been made in this the seventh edition. It is as regards the illustrations that the most extensive changes have taken place, for they now reach eight hundred, and most of them are new, and on a larger scale than in former editions. The section on general anatomy is marked by great fullness and accuracy, as well as by containing an account of the most recent observations by both British and foreign histologists. This might be expected when it is announced that Prof. Sharpey is responsible for this department. The main portion of the work is arranged according to the systematic plan, but the disadvantages to the student of practical anatomy which would thereby ensue, are removed by the addition of sections on surgical anatomy, and on the management of dissections. The former, however, merely discusses the anatomy of the parts concerned in the ligatures of the arteries, and a few other surgical operations—the abnormal positions of the bones and the actions of muscles in fractures and dislocations, as well as some other subjects often embraced in special treatises on surgical anatomy, not being included. An index, so copious as to occupy sixty-two closely printed pages, concludes the second volume; and it is made especially valuable by the fact, that the derivations of all the technical terms are given. Quain's "Anatomy" is indispensable to the teacher of the science, and is just the book with which to reward the industrious or prize-taking student.

ON DISEASE OF THE STOMACH: the Varieties of Dyspepsia, their Diagnosis and Treatment. By S. O. HABERSHON, M.D. London: Hardwicke.

TEN years ago Dr. Habershon published a larger volume than this, entitled, "Pathological and Practical Observations on Diseases of the Abdomen." That work was well received, but the author informs us that he has been advised that a smaller book, consisting chiefly of his own experience, and without the pathology, would be acceptable to the practitioner. Hence, the present production which is in effect a summary of the author's experience in hospital and private practice. The work opens with a chapter on the changes of digestion at different periods of life. Then follow more practical notes on the general sympathy of the stomach in disease; on the symptoms and general treatment of diseases of the stomach; and on remedies for indigestion and their abuse.

Dr. Habershon next proceeds to the varieties of dyspepsia, which he classifies as atonic, congestive, inflammatory, hepatic, rheumatic, gouty, renal, mechanical, sympatric, fermentative, and duodenal. Chapters on degeneration, ulcera-

tion, and cancerous disease of the stomach complete this elegant little volume. It is not to be expected that a book of this description should present much that is new or particularly striking to the experienced practitioner. It is rather a commendable feature that it should be confined to the elucidation of those practical points that come within the range of daily observation. We have read the work with considerable attention, and while prepared to admit that it is such as any hospital physician ought to be able to produce, are ready to add that the student and young practitioner will be the better for its perusal. So far as it enters into detail it is fully trust-worthy, and may be taken as a fair sample of the practice of a Guy's man. There is not the least pretentiousness in Dr. Habershon's teaching, nor is there any attempt at novelty in his book. Still less do we detect any effort to connect his name with new or peculiar remedies. In point of fact there is scarcely a prescription in the book which aims rather to inculcate the right application of principles than the use of favourite formulæ. In a second edition to which we look forward, we have no suggestions to offer the writer, unless a revision of the text, with a view to remove some marks of haste in the style, such as a little confusion resulting from the alternate use of the *I* and the *we*, which is not quite agreeable; and the correction of some errors in punctuation, which are unquestionably due to the printer's reader. After what we have said it would be superfluous to point out the chapters most worthy of attention. Each reader may select that which at the moment may appear to him most interesting.

### INSANITY OR MURDER.

THE case of KARL ANDERSON, a Swede, who was last week convicted of murder at the Central Criminal Court, cannot fail to give rise to considerable discussion. From the evidence, it is clear that he was possessed of a superstitious delusion of a remarkable kind. On the same ship on which he was engaged for the voyage was another sailor, who, though in fact a Mulatto, was generally believed to be a Russian Finn. Now, sailors—in every respect superstitious—appear to have a dread of Russian Finns; and this fear is the more prevalent amongst the Swedes. ANDERSON had several times on the voyage expressed a conviction that the vessel would never reach London unless the supposed Finn could be got rid of; he was looked upon as a “little soft” by the rest of the crew, and seems to have given various evidences of weak intellect. One day, while at the wheel, a heavy gale blowing, he said to one of the officers,

“This work will never do; we shall never get to London. I must kill that Russian Finn, and I can easily run away when I get to London.” Other indications of eccentricity, if not delusion, were observed and deposed to. This poor Swede, then—apparently urged thereto by a fearful superstition—took an opportunity one night, when on watch, to kill the poor Mulatto in his bed. There was no doubt about the murder, nor as to its perpetrator. Roused by the noise, witnesses saw him throw overboard the axe with which he had committed the crime, and seized him with the blood of the Mulatto wet upon him. Asked why he had done it, he replied—“To save all hands in the ship, and prevent her running on shore.” The man has been tried, convicted, and condemned to death, but we can scarcely believe the sentence will be carried out without further enquiry. The defence was that the act resulted from a delusion, and with so much room for a difference of opinion on such a question, we must express our surprise at the absence of scientific evidence. The jury, in convicting the prisoner, evidently decided that the plea of delusion was not made out; but in so strange a case as this we must decline to accept their verdict as decisive. From the remarks of the judge, we are unable to make out whether the verdict commended itself to his mind; but, whether it did or not, we trust that a thorough investigation into ANDERSON'S state of mind will be made by some independent persons who may be capable of forming an opinion on the subject. To send this ignorant Swede to the gallows without clearing up that part of the evidence which relates to his mental state, would shock the whole community. No motive for the dreadful deed was attempted to be shown, except that strange terror which possessed the man respecting Russian Finns—a feeling akin to that which, in days gone by, has condemned many a poor woman to death for witchcraft. In the present day, no doubt, such gross superstition even in a sailor and a Swede, giving rise to so tragic an occurrence, is calculated to surprise as well as grieve those who would scarcely have suspected its existence. But the event itself comes before us with all the circumstantial detail of a judicial proceeding, and demands the earnest attention of every well-wisher of the race. Who knows how many KARL ANDERSON'S may still be among us, doing, as this one is shown to have done, their duties in an ordinary way, and never suspected of being more than “a little soft?” On the one hand, there is danger lest such an one should be hurried on by a similar “impression” to an equally fatal act; on the other, it may be that this deed will cause many a poor fellow of weakly intellect to be looked upon as dangerous. We question, indeed, whether the punishment of this Swede would be likely to deter others equally enslaved by

superstition and ignorance, and there would seem some indication that he himself knew the consequences of his act, but was not thereby prevented from consummating it, but that he was urged on by his seemingly irresistible impulse to run the risk of a felon's doom, rather than that of the indefinable evil he believed to hang over him. For all these reasons, we submit, that there is in this case sufficient *prima facie* evidence of a specific delusion which, over-mastering the sense of right and wrong, for a time, may have rendered the man morally and even legally irresponsible for his acts. We contend that this point has not been sufficiently cleared up, that the evidence adduced at the trial was insufficient, and consequently that the verdict is unsatisfactory. We therefore ask, not only that the sentence may be stayed, but that immediate measures may be taken to bring to bear on the state of the prisoner's mind, that scientific evidence, of which there seems to have been so strange a dearth when the jury returned the verdict of guilty. To hang ANDERSON without first clearing up the doubtful points, would give rise to the most painful fears throughout the country, lest a maniac had been put to death for an act of madness.

#### ROYAL COLLEGE OF PHYSICIANS, LONDON.

At the comitia majora of this ancient College held last week, Sir. Thomas Watson bade farewell to office in an address worthy to rank with the other literary labours of the venerable Baronet. As we reported last week, there have been numerous expressions of a wish that Sir. Thomas might be induced to continue in the office he has so long filled with dignity. He felt however, the need for repose, and so firmly expressed this that no course was left but to proceed to the election of a new President. The chair has for the last five years been filled by Sir. Thomas Watson, and we need scarcely add, that the vote of thanks proposed by Dr. Burrows was carried unanimously, and with great applause.

The choice of a successor was then proceeded with. The ballot having been taken, it appeared that Dr. Alderson was elected, and he is now the President of the College.

Dr. Alderson has long been known as a physician at St. Mary's Hospital. He graduated in Arts at Cambridge in 1822, obtaining the position of sixth wrangler. He afterwards became Fellow of Pembroke College. In 1829 he took the degree of Doctor of Medicine at Oxford, and the following year became a Fellow of the College, over which he has now to preside. He has since occupied many honourable parts in his profession, and nearly exhausted the stock of distinctions. Thus, he has been treasurer of the College, and its representative on the General Medical Council of Education and Registration. He has been the President of the Royal Medical and Chirurgical Society, and has long enjoyed the coveted titular distinction of F.R.S. At the beginning of his career he practised at Hull, where he was Physician to the Infirmary. He has been connected with St. Mary's Hospital since its foundation. In 1853-4 he delivered the Lumleian Lectures at the College of Physicians. And he has contributed some papers to the

societies and the journals. So much for the promise of a popular successor to Sir. Thomas Watson, who carries with him into his retirement the warm wishes not only of the Fellows of the College, but of the whole Profession. We append his farewell address, assured that it will prove interesting to our readers:—

"While I yet have the honour of being the President of this College—before I cease to be so, as in a few minutes, upon the election of my successor, I shall cease—I ask your permission to review, very briefly, as has hitherto been my custom, and for the last time, the events and proceedings of the College during the official year which this day brings to its close; to note what we have been doing, to count our losses and gains, before the rush and hurry of modern life efface or render indistinct even the recent footprints of a single twelvemonth. I know not whether you will accept it as a justification, or as an apology, for this custom on my part, that it did not originate with me, but has simply been revived after long disuse. In the earlier annals of the College, which were kept in the Latin language—now, I am sorry to think, less cultivated and less used among us,—you will find it constantly recorded that the out-going President retired "brevi oratione habita." Such a retrospect as I propose to take ought not to be altogether uninteresting nor unsuggestive.

"Some of our incidental doings have assumed an annual character, and need not be dwelt upon, having become almost matters of course. Thus we have again been glad to house the Medical Council, and to give up our rooms for a day to the Medico-Psychological Association.

"There has been the customary interchange of complimentary messages and requests, shall I call them tasks, from her Majesty's government, and of gratuitous service on our part in return.

"The labours of the Leprosy Committee have been completed, and their results embodied in a comprehensive report of great interest and value.

"At the instance of the Privy Council we have drawn up rules for the guidance of the captains of merchant vessels, respecting the measures to be adopted in any sudden outbreak of cholera on board ship.

"I had hoped that the much-looked-for report on the Nomenclature of Disease might have been presented to the College during my presidency; but it is not quite, though it is very nearly ready.

"It will be satisfactory to the College to know that a warrant has recently been issued in full conformity with the recommendations of the committee which was appointed last year—mainly at the instance of this College—to inquire into the pay and precedence of the medical officers of the army.

"The portraits which were lent by the College last year for the National Portrait Exhibition at Kensington have been duly and safely returned; and other portraits, of a later period, have been lent for the forthcoming exhibition of the present year.

"The College has granted a contribution of £25 towards a statue recently erected at Boulogne in honour of our countryman, Dr. Edward Jenner.

"We have received many valuable presents: books as usual, in large numbers; the portrait in marble of the late Dr. John Conolly, which will be presented to-day; the portraits of the late Dr. Spurgin, from his widow, and of the late Dr. Gooch, from his daughter; and some admirable drawings illustrative of the pathology of the cattle disease, from the Cattle-plague Commissioners.

"The statutory lectures have been delivered before the College—by Dr. Reginald Southey, Dr. Andrew Clark, and Dr. Russell Reynolds; and they were all in my judgment, who heard them all, able, interesting and instructive discourses, and worthy of our body.

"Dr. Burdon-Sanderson has also, in a supplementary lecture, explained and illustrated some important points connected with the arterial pulse, and the mode and duration of the heart's contractions in health and disease; and Dr. Anstie has yet one or two lectures to deliver on the same or on similar subjects.

"Our losses from death among the Fellows, during the past year, have been unusually heavy and grievous—not only from the number, but from the quality also of those who have died. Of this there is significance enough in the mere fact that all of them were or had been physicians or assistant-physicians of hospitals in London. All too, with a single exception, were

graduates of one or the other of our old Universities of Oxford and Cambridge; a class which, I may be permitted, without offence I hope, to declare my individual regret, is becoming comparatively less and less numerous among us.

"Let me notice rapidly, and in outline, some of the characteristic features that distinguished these men—taking them in the order of their seniority in the College list: Seymour, Babington, Jeaffreson, Sutherland, Barlow, Brinton, Woodfall.

"Dr. Seymour was not much known, I think, except by the older Fellows of the College. Yet he was at one time, and for many years, in large repute and practice. He began as a physician in Florence, where he made many influential English friends, who were afterwards of great service to him in London. Broken health, and broken fortunes, obscured his latter days. He possessed in no common degree the enviable gift—whether it be of voice, look, manner, or I know not what—of securing at once the confidence of those who consulted him; a gift which has made the fortune of many a physician of much less talent and information than Dr. Seymour, and the want of which has hindered the progress and marred the prosperity of many of far greater attainments than his. Dr. Seymour wrote on several subjects; and, by a not very unusual, but to me a puzzling inconsistency, he wrote less well than he spoke. He was much consulted, and his judgment was deservedly esteemed, in cases of insanity. He held, indeed, for some time the office of Commissioner in Lunacy. He was one of the first who used opium freely in the treatment of that terrible form of disease.

"Dr. Benjamin Guy Babington was the worthy son of a most worthy sire, who was himself a Fellow of this College, and whose shrewd and benevolent features are faithfully and admirably expressed in the marble bust beside us. The son was originally a midshipman in the Royal Navy, and served, together with the present Lord Chancellor, in that capacity at Copenhagen. But he soon transferred himself to the civil service in India, where he passed much of his earlier adult life, and where he acquired an accurate grammatical knowledge of the Eastern languages. Though he came late into our profession, and was of a modest and unassuming character, he achieved considerable distinction as a physician in London. His name will live as the founder, and for many years in succession the president, of a society which has for its end the elucidation of one of the most interesting, important, and obscure subjects of medical inquiry—the sources, constitution, and laws of epidemic diseases. Among various other contributions to medical science, he gave to English literature an admirable translation of Hecker's "History of the Epidemics of the Middle Ages." He possessed great versatility of talent. Excelling in those things that require perfection of the senses—accuracy of eye, agility of limb, delicacy of touch—he was, in sportsman's phrase, a good shot, a skilful billiard player, and no mean modeller. Nor was the inventive readiness of his mind less marked than were his bodily facilities. To take one instance only: he could claim the credit of having been the first to devise, nearly forty-five years ago, a method for bringing the organ of the human voice within the ken of the human eye—of being the inventor of that ingenious instrument with which, in a greatly improved form, we have since become familiar, under the untunable name of laryngoscope.

"The valuable life of Dr. Jeaffreson was prematurely lost while he was engaged in actual conflict with disease, and in the conscientious discharge of his professional duty. He died of a fever, which he caught from one of his patients. His practice in the city and its neighbourhood became early both extensive and fertile. He was a successful physician in both the meanings of success. But expending the whole force of his mind in the practical business of his calling—for he wrote nothing, though an hospital physician he never lectured—he has unfortunately left the world no record of his accumulated and ripe experience; but he *has* left behind him, among all who knew him—among friends, companions, and patients alike—a widely-felt, well-founded, and abiding sense of profound esteem and affectionate regret. He was one of the most kind-hearted and popular men within our body. It was lately remarked to me by a distinguished Fellow of the College who had known them well that he had never heard either Dr. Babington or Dr. Jeaffreson say an unkind thing of any man.

"The last four years of Dr. Sutherland's life were passed in the gloom of hopeless disease. In that department of practice which he specially cultivated, and in which his name had hereditary weight and distinction, his mature experience, his discriminative skill, his wise discretion, and his honourable

nature have been greatly missed by many a sorrowing family; for these are qualities which are peculiarly needful and precious where mental disease is present in its varying shapes of misery and terror, and they were conspicuous qualities in Dr. Sutherland. It is to be added to his great credit and praise, that twenty-five years ago he persuaded the governors of St. Luke's Hospital to revive the practice—for it was not altogether novel—of admitting a certain number of selected students to the wards of the hospital for the purposes of study and instruction. St. Luke's was the first hospital, in this country at least, where that wise and salutary privilege was granted. It was obtained by Dr. Battie about the middle of the last century; but it had long fallen into absolute disuse. For several years Dr. Sutherland gave gratuitous lectures there, illustrating them clinically by actual examples, upon the supremely interesting subject of insanity.

"Dr. Barlow was a quiet, undemonstrative, yet withal an able, full, and accomplished physician, of which, were there no other evidence, his well-known Manual of the Practice of Medicine would furnish ample proof. Pursuing the even tenour of a blameless, beneficial, and laborious life, displaying "the power of art without the show," Dr. Barlow's career presented—may I not say for his own sake, *happily* presented—no very prominent points upon which to hang even such hasty shreds of biography as alone I have time, or dare to presume, to attempt.

"I have spoken of the death of Dr. Jeaffreson as untimely; indeed I might with truth say the same of almost all of those whose departure from this world it is my melancholy duty to commemorate to-day. But most emphatically may that epithet be applied to the death of Dr. Brinton, who was taken away in the very prime of his life, when, having overcome many obstacles, he had just begun to taste that fruit of fame, with its attending rewards and privileges, for which he had earnestly wrought, and which he so eminently merited. I cannot claim him as one of my own pupils at King's College; I am too old, or rather he was too young, for that; but he was a most distinguished student in that school, and I may, perhaps, venture to say he was somewhat hardly used there. He graduated at the University of London. Dr. Brinton was endowed by nature with all the main elements of success: a clear and acute intellect, untiring and methodical industry, great tenacity of purpose, a remarkable facility in acquiring and in imparting knowledge, and very engaging manners. Among numerous contributions to the literature of our profession, his writings on the diseases of the alimentary canal are the most prominent and the most original. He was the first to teach the true pathology of fæcal vomiting, and to settle, for all time, the nice and anxious management of intestinal obstructions. His accomplishments were many and various, and he put into his very recreations the same spirit and energy as were manifest in his scientific pursuits. He was ready and expert with his pencil; a clever caricaturist I have been told, yet assuredly not an ill-natured one. An active and ardent explorer of Alpine scenery, he constructed, on a large scale, diagrams—by which I have myself profited—of some of the most remarkable and least frequented passes in the mountains of the Tyrol. He was, moreover, though this does not seem to have been so generally known, a poet. I have in my possession a translation by him of Bürger's "Lenore," which, as I have been assured by one of our Fellows thoroughly competent to judge on such matters, is, in reference to the original German, equal, if not superior, to the well-known version of the same poem by Sir Walter Scott.

"The last of the Fellows whose death we have to deplore is Dr. Woodfall, beneath whose unpretending and even shy outward demeanour lay hid a fund of good sense, intelligence, and high and honourable feeling; hidden, I mean, from the observation of those with whom he was not familiarly intimate, yet sure to be recognised and appreciated in the end by all with whom he came into closer contact. He was one of those men, to whom I have already adverted, who, through a lack of self-assertion, are not adequately estimated by their fellow-men. After some attempts to settle himself in London, he retired to Maidstone, where his worth became known, where his death is even now a recent sorrow, and where (I use and echo the words of one of his professional brethren who wrote to report to me his loss) he was widely esteemed 'as a kind and amiable gentleman and a good physician.'

"These were men whom the College, while it mourns them, must sorely miss. On the other hand, we are not left without solace and compensation. During this year of disaster in our ranks we have not failed to ingraft upon our stock fresh names,

which I need not rehearse—names of younger and vigorous workers, by whom, in due time, I feel confident the serious losses we have been lamenting will be amply repaired.

"Eleven new Fellows have been admitted: our whole number is therefore increased by four. Seven Members of the College have died within the year, and sixteen have been added to the list; making an increase of nine.

"It only remains that I should attempt to do that which I feel to be well-nigh impossible—to embody in any form of words that I can devise, the deep and inextinguishable sense of gratitude with which my mind is full, for that kindness and trust which have placed me, year by year, on five successive occasions, at the head of the College of Physicians; in other words at the head of the medical profession in this great country. According to my estimation, already more than once expressed, there is no nobler position in medicine, whether I look before me and around me, to the body of men from whom it comes—or backward to the splendid list of names of those who have preceded me in the presidential chair. Linaere, Caius, Glisson, Sir Wm. Browne, Pitcairn, Sir George Baker—these, to go no later, are but a few of the eminent men and sound scholars with whom it may well be deemed a proud distinction to have one's name in any way associated. But besides this great and repeated honour—the greater because so repeated—I have much else to thank you for. I have to acknowledge your indulgence towards the many shortcomings of which I am but too conscious. I have to express my thanks for your constant support and counsel in all difficulties, for your unvarying courtesy and deference, for the friendships which my official intercourse with you has formed or strengthened, and most especially for that recent signal and touching evidence of your approbation and esteem, shown by your wish to possess within these walls some pictorial remembrance of my unworthy person. Of this high and generous compliment, I will never, while life and reason remain to me, be otherwise than most gratefully, and I hope pardonably proud. Furthermore, I have to rejoice that the happy lustrum during which I have presided over your affairs has been harmonious and peaceful, disturbed by no unseemly quarrels or serious differences among us—stained by no scandal arising within our professional body, and productive, through your exertions and self-sacrifice, of something at least of benefit to the common weal. If I find anything to regret, it is that I have not taken larger advantage of the opportunities which you have confided to me of promoting the interests of the College, and of our useful and noble Profession. Still, I must cherish the hope that the College has suffered no abatement of its ancient dignity and renown through my occupation of the office which I now respectfully render back into your hands. And so, without encroaching further upon your time, and in redemption of the pledge which I gave you last year, I bid you, as your President, one and all, a cordial, affectionate, and final farewell."

#### REFORM IN THE LONDON COLLEGE OF SURGEONS.

It is now positively announced that this most Conservative of our Corporations has entered on the path of Reform. Truly we live in an age when events move rapidly. We have a Conservative Government bidding against their old political opponents on the question of Parliamentary Reform, and the equally anomalous fact of the London College of Surgeons listening to the voice of the Profession, and consenting to the changes that have long been demanded. What then is the sum and substance of the concession offered? Henceforth every aspirant to the M.R.C.S. must produce evidence of having passed some examination in Medicine, or must be examined on that subject by a Board appointed by the College before receiving his diploma. Certainly this is a step. We regret, however, the idea of erecting another examining board. These separate "little goes" will never add to the dignity of the Profession, nor would they be tolerated, but for the numerous Corporations which possess the right to grant diplomas; and it would be much more satisfactory, both to the Profession and the public, if an arrangement were made whereby a full examination on all necessary points

should be undergone before any diploma whatever could be obtained. We have already alluded to the negotiations that have for some time been carried on between the Colleges of Surgeons and Physicians, and we greatly regret that so little good should have been effected. They have managed much better in Scotland, and as the communications between the two London Corporations are still active, we may yet hope to see an equally favourable result. Since the passing of the Medical Act it has been more than ever important for every professional man to have both a medical and surgical qualification, and we cannot but feel that the union of two corporations, already so successful in Edinburgh, to accomplish the object is the simplest solution of the difficulty. The most unpromising part of the whole question is the financial one. The fees at both the London Colleges are heavy, and to double them is no doubt a hardship on the candidates. Mutual concession is the only suggestion we have to make on this point, to which we may add the imperious necessity of quickening their action. While their negotiations "drag their slow length along," young men are growing up and resorting to other institutions. A medical and a surgical diploma is the requirement—all the Universities offer the former, the several Colleges the latter. The Universities now grant a Mastership in Surgery to their medical graduates at a moderate fee. Those who cannot offer themselves for this qualification can go to any College of Surgeons and add to that diploma the very cheap, and we are bound to add, the really respectable, license of the Apothecaries' Society. This last body has done so much to advance the interests of the Profession, and has conducted its examinations of such a spirit, that they will always be esteemed, and unless the London College of Physicians or the Universities should concede a good deal in the way of fees and restrictions, it may count on a long career of continued usefulness.

Our attention has been called to the following semi-editorial paragraphs which appear immediately after the leading articles in the *Cork Reporter* of the 13th inst. We inflict them *in extenso* on our readers, firstly as an instructive lesson as to what, as honourable practitioners, they ought to avoid, and secondly, lest we should be retorted on with a charge of garbling:—

#### "CORK AS A SEAT OF LEARNING.

"That brilliant epoch in Irish history, when votaries of learning came from all parts of civilized Europe to receive instruction in the "island of saints and sages," seems likely to be reproduced in our own days and in our own city. It is a well-known fact that many individuals have in past years come from the most distant parts of the globe to study law under the able professors of that faculty in the Queen's College here. There are at the present moment several students in that college who have come from very distant places to pursue their studies, and who, of course, selected the place where they expected to enjoy the instruction and counsel of the ablest professors. Amongst those attending the lectures of Dr. Corbett, Professor of Anatomy and Physiology, there are several strangers, including two gentlemen from the West Indian Islands, one from China, two from Dieppe, five from London, Liverpool, and other parts of England, three from Belfast, two from Dublin, &c. This fact speaks trumpet-tongued as to the efficiency of the instruction given by Dr. Corbett, and shows clearly that not only have his abilities been appreciated, but that the fame of his teaching has extended very considerably. A splendid lecture-room and anatomical theatre have just been added to the medical department of the College, owing solely to the forcible manner in which Dr. Corbett pressed on the late Government the necessity of additional accommodation for the numerous students resorting to the

Cork School of Medicine. It is gratifying to be able to direct public attention to these facts, and to feel that in some instances at least the "right men are in the right places."

"DOCTOR TANNER ON SURGERY.

"A rare opportunity of becoming practically acquainted with the manner of performing all those surgical operations, which accident or disease may render necessary, has just been afforded to the gentlemen studying medicine in our city. Dr. Tanner, Professor of Surgery at the Queen's College, senior-surgeon to the County Hospital and South Infirmary, and a practitioner, whose ability and skill have placed him in the foremost rank of his profession, and made his name become known throughout, at least, the South of Ireland, has just concluded an extensive special course of lectures on Operative Surgery, which he has, for some months past, been delivering at the College. This course was distinct from the regular lectures on Surgery, forming a part of the medical curriculum. In addition to pointing out the physiological and anatomical considerations, and the scientific principles on which the several operations were based, he explained and contrasted the different methods proposed by the most eminent continental, and English operators, and his own mode of procedure in those cases in which he deemed improvement admissible. He illustrated his observations by the performance of various operations on the human body. It is unnecessary to allude to the advantage to be derived from attendance at lectures of such a kind, when delivered by so skilful a practitioner and so dexterous a manipulator. The lasting benefit that they must confer on those who had the good fortune of attending them is incalculable. It is unnecessary to mention that lectures so replete with interest, and so full of instruction, and on a subject of such momentous importance, were flocked to day after day with the utmost eagerness. The suggestion of giving these special lectures came from Dr. Tanner himself, and was of course cordially approved of by his pupils. And although every gentleman attending them was willing to pay largely, Doctor Tanner insisted on their being gratuitous. When the additional trouble and the loss of time thus willingly entailed on a busy practitioner are considered, an idea may be formed of the extent of this boon, which is only one of the many unselfish acts for which Doctor Tanner has become proverbial."

The position which Dr. Corbett and Dr. Tanner have hitherto held in Cork, and their high official connection with the Queen's University in Ireland, the Senates of which are presumed to exercise a certain censorship in such matters, give us grounds for the hope that these most unprofessional pseudo-editorial notices were published without their privacy, and contrary to their feeling of medico-ethical honour. Having had no personal knowledge of or local connection whatever with these gentlemen, we cannot be accused of personal animus; and we are slow to believe that medical men holding their rank could for a moment countenance a system of advertising, which should be denounced, if adopted by the commonest surgical journeyman; and we put it plainly for their consideration, whether they will permit their names to be associated in such a transaction without a decisive and immediate repudiation.

## Notes on Current Topics.

UNIVERSITY BOAT RACE.—On Saturday last the great boat race between the two English Universities, Oxford and Cambridge, came off as usual on the Thames, between Putney and Mortlake. The interest felt in this annual contest seems to have increased year by year, until at length it has equalled that which some of our most noted race-courses produce. Thousands of people were seen crowding the banks of the river soon after eight in the morning, notwithstanding the inclemency of the day. The weather was cold, and the rain came down incessantly, yet the crowds held their place, waiting under their dripping

umbrellas the result of the strife. It was arranged that the start should be made at eight o'clock, but a delay occurred from some cause or other, and it was not until a little before nine that the competitors took the water, and rowed to the starting point. Oxford had the advantage in the choice for place, which she had won. At length the word was given, and the boats were off. It was doubtful all along, from the very first to the last moment when the winning flag was passed, on which side the victory would lie, and the excitement among the spectators during the whole course was intense. Sometimes Cambridge, soon after starting, got a little a-head; then Oxford, by its deep strong pulling, got up again. At Hammersmith Bridge, Cambridge was nearly her whole length in advance, and was loudly cheered by the spectators as she glided beneath it, but afterwards Oxford drew up again amidst deafening cheers, and maintained her superiority for some time. These alternations continued almost to the last, and the issue seemed doubtful up to the very minute when the victory was won—and it was only when the flag was passed and Oxford declared the winner, that any certainty was felt. The rapidity with which they passed along was wonderful, a course of nearly four miles and a-half being concluded in twenty-two minutes thirty-nine seconds. We give a table of these University matches from the first:—

Year.	Winner.	Course.	Time.	Won by
1829	Oxford	Henley	14m. 30s.	Many laths.
1836	Cambridge	Westminster to Putney	36m.	1 minute.
1839	Cambridge	Westminster to Putney	31m.	1m. 45s.
1840	Cambridge	Westminster to Putney	29m. 30s.	2-3 of a lath.
1841	Cambridge	Westminster to Putney	32m. 30s.	1m. 4s.
1842	Oxford	Westminster to Putney	30m. 45s.	13 seconds.
1845	Cambridge	Putney to Mortlake	23m. 30s.	30 seconds.
1846	Cambridge	Mortlake to Putney	21m. 5s.	Two laths.
1849	Cambridge	Putney to Mortlake	22m.	Many laths.
—	Oxford	Putney to Mortlake	A foul.	
1852	Oxford	Putney to Mortlake	21m. 36s.	27 seconds.
1854	Oxford	Putney to Mortlake	25m. 23s.	11 strokes.
1856	Cambridge	Mortlake to Putney	25m. 30s.	½-a-length.
1857	Oxford	Putney to Mortlake	22m. 50s.	35 seconds.
1858	Cambridge	Putney to Mortlake	21m. 23s.	22 seconds.
1859	Oxford	Putney to Mortlake	24m. 30s.	Camb. sank.
1860	Cambridge	Putney to Mortlake	26m.	A length.
1861	Oxford	Putney to Mortlake	23m. 27s.	48 seconds.
1862	Oxford	Putney to Mortlake	24m. 40s.	30 seconds.
1863	Oxford	Mortlake to Putney	23m. 5s.	42 seconds.
1864	Oxford	Putney to Mortlake	21m. 45s.	23 seconds.
1865	Oxford	Putney to Mortlake	21m. 23s.	13 seconds.
1866	Oxford	Putney to Mortlake	25m. 45s.	15 seconds.
1867	Oxford	Putney to Mortlake	22m. 39s.	½-a-length.

To medical men, one of the most interesting considerations respecting these matches would be the effects upon the health, of the great strain and excitement to which the competitors are of necessity subjected. It is to be regretted that no exact data have been collected, but we may be sure that none but thoroughly sound constitutions should run the risk of such an ordeal.

STRANGE DEATH OF A MEDICAL MAN.—At a private hotel in Arundel-street, an extraordinary death occurred some days ago. From evidence before the coroner, it appears that the deceased was a doctor. He was last seen alive on Sunday week, when he complained of a violent cold and bleeding at the nose; he was evidently unwell and depressed in consequence of the affection at his chest. He was seen to go into his room at twelve o'clock on the Tuesday, but was never seen alive again. On the Saturday following the waiter was sent up to look through the glass over his door, with a view—as deceased said he was going out of town—to see if he had taken his luggage with him, when he saw him lying dead on his bed. Dr. Alfred Harvey was called, and found him in the position described—a blue tinge on the face, the eyes dilated, the knees bent,

and he seemed to have been dead some days. "In a desk close by was some soap liniment and opium, which, no doubt, would have been applied to the chest." By the *post-mortem* examination, the brain was found much congested, but no trace of poison in the body, and he gave it as his opinion that death resulted from congestive apoplexy. The jury returned a verdict accordingly.

**UNIVERSITY FRANCHISE.**—When the Reform Bill was first brought before Parliament, we directed attention to the fitness of University Graduates for exercising the franchise, and urged the erection of new University constituencies. We are glad to find that the University of Edinburgh has taken up the subject, and petitioned the Government. The Edinburgh University offers a constituency of 2000, which could easily be increased by another 500. As to numbers it has, therefore, a better right to one member than either Oxford or Cambridge has to two. We should be very glad to see the petition granted, and we think the other Universities that are not represented may very fairly lay claim to the privilege.

**MEDICAL COUNCIL.**—It is understood that the meeting of this body, which was to have taken place in May, has been postponed. The cause assigned for this is that the Home Secretary has not yet signified the intentions of the Government about the proposal for an amendment of the Medical Act. Is there no other way of meeting delay on the part of the Government than a corresponding procrastination by the Council? If not, we shall expect to hear but little further of the bill.

**VIVISECTION.**—Our columns have been more than once occupied with the horrors of vivisection, and opinions in accord with those we have expressed have been echoed by a large number of our contemporaries. We are happy to be able to record the following almost official protest:—

"We, the Court of Examiners for Scotland of the Royal College of Veterinary Surgeons, desire to express our opinion that the performance of operations on living animals is altogether unnecessary and useless for the purpose of causation:—

"JAMES SYME, Chairman.

"JAMES DUNSMURE, M.D., P.R.C.S.E.

"J. WARBURTON BEGGIE, M.D.

"JOHN LAWSON, President of the Royal College of Veterinary Surgeons.

"R. CARTLEDGE, M.R.C.V.S., Consulting Member of Council.

"WILLIAM COCKBURN, M.R.C.V.S.

"WILLIAM ROBERTSON, M.R.C.V.S.

"CHARLES SECKER, M.R.C.V.S.

"JAMES COWIE, M.R.C.V.S.

"I fully concur in the above.

"WILLIAM WILKINSON, Principal Veterinary Surgeon to the Forces."

**FRIGHTFUL MORTALITY.**—Reports from the Mauritius inform us that yellow fever is rife to a fearful extent among the Indian and Creole population of that island. Last year it appears that the average death-rate in Port Louis was 10 per day, which subsequently increased, till at the time the intelligence was sent off it had reached from 95 to 100, and for the whole island about 200 per day. Burials were constantly taking place, and the epidemic was interfering sadly with industrial employments of all kinds. "Temporary hospitals were being erected every where. Quinine, the principal remedy, it is said, has reached a fabulous price, one ounce being sold for 137 dollars, or £27 8s., there being but a few ounces left in the island."

**CORONER'S REPORT.**—A few particulars selected from the annual report of Dr. Lankester, the Coroner of Central Middlesex, may not be uninteresting to our readers. He and his deputy, Dr. Hardwicke, held no fewer than 1385 inquests during the year, being 139 more than the previous year. He classifies the causes of these deaths, and records the singular fact that the average of infanticide and fatal accidents is steadily increasing, while that of all other causes remains just where it was. In connection with infanticide, he thinks there ought to be a registration of still-born children. He remarks on the subject of infectious diseases, that in some of those cases which came before him, there was "evidently gross neglect of the most ordinary sanitary arrangements," to which he attributed the death. He thinks that the advantage to the public of these inquiries is not yet fully apprehended. It has been found that the inquest with its consequent verdict has, in many cases, aroused the neighbourhood, and led to immediate sanitary improvement. During the past year small-pox made its appearance in London. Several hundreds have lost their lives by that epidemic, which is still extending. This disease, he says, he feels assured, has arisen and spread through neglect of vaccination, and he has felt it his duty to hold inquests when he knew that children had died of that disease without being vaccinated, as he considers that such cases come as much under his supervision as all causes of death which might by care and forethought be avoided. Vaccination is important in several respects. Persons who have been vaccinated and who take small-pox, are not so likely to die as the unvaccinated. Those not vaccinated take the disease more largely in proportion to their numbers than the vaccinated, and thus become the means of spreading this loathsome and dangerous disease. There is a law of fine for not having children vaccinated, and he suggests, whether, under all these views, persons who violate that law are not liable to a verdict of manslaughter, if it is shown that the children thus neglected die of small-pox. On suicide he remarks, its "permanence," its "mystery," suggests the necessity of the Coroner having power to hold inquests on all persons dying in workhouses as well as in prisons, and points to the fact that reform in workhouse management has originated in the Coroner's Court.

**PAUPERISM IN WINTER.**—The past winter has been characterised by the large amount of distress which has prevailed in this country. The severity of the weather was undoubtedly the cause of the increase in the number of persons applying for relief above that of last year. In January, when the frost was keenest, the destitution was greatest, as the returns of the Poor-Law Board for that month will show. The proportion was very unequal in the different divisions of the kingdom—in the metropolis it exceeded that of any other part, showing that where wealth abounds, poverty abounds also, but there was no one of the divisions where the pauperism did not exceed that of last year. Thus, in the district least affected, the number of persons receiving relief in January last, was 2·7 per cent. more than in the same month last year, while in London it was no less than 72·6 per cent. For more than three years, in the north-western division, pauperism had declined month by month, when suddenly, in January, 2000 a-day were added to the 100,000 already existing, and in London, for a fortnight, nearly 3000 a-day. The contributions of the charitable flowed in, and the grand

cause—the cold—abating, the destitution was much lessened at the end of the month, so that in the same districts the increase, instead of being respectively 27·4 and 72·6 per cent., became 12·7 and 57·3 per cent., and in the whole of England it was reduced to 13·7 per cent.

**HEALTH OF SCOTLAND.**—Prosperity in commerce and manufactures is generally followed by an increase of the marriage-rate in any locality where it occurs. There has been great demand for labour, and high wages at Greenock, in the iron ship-building yards for some years past, and consequently the marriage-rate has been higher there than in all the other Scottish towns. But the strike for higher wages in the latter part of 1866 has reduced the marriage-rate below that of four other large towns. Thus, in the first quarter of 1865, the marriages were 151, and only 85 in the first quarter of 1867. Dundee had the largest proportion of marriages in 1866, owing, no doubt, to the great increase in the manufacture of flax, jute, and hemp. In the eight principal towns of Scotland the marriages in the first three months of the present year have been fewer than in the first quarter of the two preceding years, and the same likewise with the births, notwithstanding the high marriage-rate of the last two years. The aggregate population of these towns is about 944,000, and there have been registered the first quarter of this year 9539 births, 2068 marriages, 7457 deaths. The severe cold in January is considered to be the cause of the large mortality of that month—the mean temperature averaging only 0·9 above the freezing point, the lowest since it began to be registered in Scotland in 1855. In February the temperature was considerably above the average, but in March, as much below; and the mortality in these months was below the average, so that though it was high in January, yet in the quarter it was below the average of the same quarter in two previous years. Typhus continues epidemic in Scotland to a certain extent, and has caused 368 deaths in the last quarter in the eight towns referred to. Cholera caused 9 deaths in January, 3 in February, but none in March; diarrhoea 104, which is a larger number than usual for that period of the year. The mortality among children was large in 1866, above thirty-eight per cent. of the deaths. The Registrar-General gives the following figures:—Of children, under 5 years of age, 5·4 per cent. died at Perth; 7·4 per cent. at Paisley and Leith; 7·7 per cent. at Edinburgh; 9·7 per cent. at Greenock; 9·8 per cent. at Glasgow; and 10 per cent. at Dundee and Aberdeen. Hence, the deaths of children seem proportionate to the largeness of the population. Zymotic diseases have been prevalent in these last two towns.

## Correspondence.

### THE BAKER BROWN PERSECUTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I beg to hand you the report of two speeches made by Dr. Hall Davis, which I have extracted from the printed proceedings of the annual meetings of the London Surgical Home.

I am at a loss to know how to reconcile these speeches with the conduct of Dr. Hall Davis as President of the Obstetrical Society, when he permitted Mr. Seymour Haden to indulge, unchecked, in abuse and insinuations against Mr. Baker Brown that had no foundation in truth, as also against an Institution, that, in addition to Mr. Brown, has had on its staff, and now has, gentlemen, who, if they cannot vie with Mr. Seymour Haden in his singular way of showing his regard for

truth, are at least entitled to the respect due to their opinions. Prominent amongst these stood Dr. Hall Davis, whose report is confirmed by a numerous and influential body of Medical men in all parts of the world, the written evidence of which is in the possession of your obedient servant,

HOLT DUNN.

*Extract from the Proceedings of the Third Annual Meeting of the London Surgical Home, June 19th, 1861.*

“Dr. HALL DAVIS:—I beg to return you the sincere thanks of the Medical staff for the kind manner in which the thanks of the meeting have been proposed and responded to. For my own part I cannot lay claim to even a small portion of the thanks that have been accorded to us. My services in this Institution are of a very subordinate character, of a very light description, though, upon all occasions on which I have been called upon to assist my colleagues in anxious deliberation upon the critical cases that have come before them in this Institution, I believe they have ever found me ready to attend. During my different visits to the Institution, I have been present at many of the operative proceedings, and I may say that those operations have interested me very greatly, not only on account of the high object at which they aimed, but on account also of the great coolness, the great moral courage, the great skill, the delicacy which has characterized the performance of those operations. As I am not an active member of the staff, and only attend professionally upon certain occasions, and other times when my interest may lead me there, I take this opportunity of congratulating Mr. Baker Brown upon the great success which he has attained in the treatment of the special diseases which have come under our notice; diseases which, for many a long year, have been the opprobrium of our hospitals, and have admitted of no cure, though I have frequently witnessed attempts, yet I have seen those attempts disastrously fail. At one time I knew very little about this Institution, but as soon as I came to know of its beneficial operations, I did not allow myself to be prejudiced by a great many remarks which were made with regard to the proceedings of Mr. Brown at this Institution, but I thought it only fair to that gentleman that I should examine into the matter myself. Being lecturer on a very important department of medical treatment in reference to the diseases of females, it was my duty, I thought, to investigate the matter, and to see how much of truth lay in the statement which has been made, and I was very much pleased, I may say, upon my first visit, still more pleased upon my second and third visits, and the consequence was my visits ultimately became more frequent, and I was induced, upon the success of a very severe case which Mr. Brown admitted to me was one of the most severe cases he had ever met with, to place another case under his care, in the cure of which there was no hope to be expected from any other institution, and I am glad to say that the patient was completely cured within a very few days; she had been for many years a very severe sufferer, but Mr. Brown, with his admirable skill and dexterity, effected a complete cure of the patient. I have seen a great many operations at the Home, and I have been struck with admiration at the great skill and the great coolness which have been exhibited on those occasions, and when I make use of the expression ‘coolness’ I do not mean that there was any want of feeling on his part, there was great feeling exhibited, and great humanity has characterised all the proceedings of the Institution, and pervaded the entire establishment. The patients are loud in their expressions of gratitude to everybody concerned in the active proceedings of the Home, the lady visitors, the lady superintendent, the clergy, the nurses, and the medical officers, and they are especially loud in their grateful expressions to Mr. Brown for the very kind and skilful care which he has shown in the treatment of their cases.”

*Extract from the proceedings at the fourth Annual Meeting at the London Surgical Home, Tuesday 24th June, 1862.*

“Dr. HALL DAVIS:—I beg to move, ‘that the thanks of this meeting be hereby given to the trustees, to the treasurer, and to the auditors, for their kind service during the past year.’ It was not my intention to have made any remarks at this late period of the meeting. I would rather have spared the patience of the ladies who have kindly given their presence to day, had not Mr. Baker Brown kindly expressed his opinion of the humble services which I rendered, or rather have rendered during the last two years to the Institution, which services were rendered with very great pleasure and willing-

ness, and not altogether without a very considerable return in the way of compensation to me for my expenditure of time which I bestowed. During my attendance I have been very much gratified with what I have read, and have been very much gratified with the results of the treatment of the most difficult and critical cases, and cases which only a few years ago were held to be totally incurable. I have been very much pleased, and very much obliged to Mr. Baker Brown for his kind attention on different occasions to patients whom I have sent into the Institution myself, who had no opportunity of being satisfactorily treated, at least, in my opinion, elsewhere, more especially on account of want of proper appliances, and want of proper nursing, and the want of that amount of fresh air which fortunately is supplied to the patients who come into this Institution. The consequence of all these advantages which patients receive in this Institution is, that the percentage of cures is very much larger than is obtained in many other Institutions. Mr. Baker Brown has great reason to be proud, as Mr. De Meric very truthfully observes, when he looks back upon the results of his own treatment, assisted by the co-operation of his intelligent colleagues; results, not only here, but in other parts of the world. Operations performed here have been repeated in other institutions where heretofore, they were not attempted. The example has been set here of undertaking very bold operations—operations, however, which are justifiable, inasmuch as without them there was nothing left for the poor patient but utter hopelessness and misery for the rest of her days. But by the skilful appliances of this Institution, and by the courage and skill displayed in the wonderful operations of Mr. Baker Brown, the greatest success has been achieved in many instances where, in other institutions, no hope whatever was held out to the patients. I can fully endorse all that has been said by Mr. De Meric, and also by Mr. Brown, with regard to the advantages which have been afforded by this Institution, as regards the appreciation which the efforts here have met with on the part of foreigners. I have been present at a large number of operations during the two years I have had the good fortune to be connected with this institution, and it has been a great pleasure to me to see the great interest which has been shown by these foreigners in the operations that were performed. I was not at all surprised at that interest, when I considered the extreme delicacy and consideration with which these operations are gone through, and the great courtesy shown by Mr. Brown, and the great readiness he has always manifested to communicate the extensive information he possesses with regard to those most intricate and difficult operations. My thanks I again beg to tender to Mr. Brown for his extreme kindness in expressing himself in the manner he has done, and also for the courtesy and good fellowship which he has shown upon all occasions during my connection with the Institution in the last two years. He has, he may feel well assured, my best wishes for his success—and success has always been associated with him—and for the success of the Institution.”

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Rev. J. P. Gell presents his compliments to the Editor of THE MEDICAL PRESS AND CIRCULAR, and begs to submit for publication a copy of the letter addressed to Mr. Isaac Baker Brown by the clergy visiting the London Home, a copy of which has been sent to the Council of the Obstetrical Society. The Home is within Mr. Gell's parochial charge, and the clergy of the three adjoining parishes are included among the visitors:—

“SIR,—We have received the proceedings of the Obstetrical Society of London, on the 3rd inst., as published, resulting in your removal from the Society by 194 votes to 41.

“We regret the character of Mr. Haden's attack on you, part of which was only uttered to be withdrawn by himself, and part was disposed of by the President in ruling that the Society had not met to consider a specified operation, but the manner in which you had performed it.

“Still more do we regret that Mr. Barnes, the supporter of Mr. Haden, should have avowed to you that my friend cannot be yours; and, with such a sentiment on his lips, should have been appointed (as the *Lancet* reports) a scrutineer; and that the President should have directed the ballot to proceed, ‘for the convenience,’ as the Secretary explained, ‘of those who have made up their minds one way or the other,’ before you could begin your reply, but after Messrs. Haden and Barnes had been heard.

“But, more deeply do we regret, that the charges of operating for improper reasons—*i.e.*, for cure of cases legally inadmissible at the Home, and in an improper manner—*i.e.*, unknown to the natural protectors of the patient, should have been partly admitted by yourself, and partly established by the evidence; and that when Mr. Pym had your authority for writing to the papers on the 4th February last, to say that you had given up an operation which had been brought in question, pending professional inquiry, you nevertheless repeated it in a modified form on the 21st of February, in the presence of Mr. Locking.

We would remind that you told us, at a public annual meeting at the London Home, that with regard to hysterical mania, many cases had been brought in, and almost without exception cured; and, we think, the same information should not have been withheld from the Commissioners of Lunacy when they sought for it. Such candour, even had it involved a sacrifice, would have better sustained the high character the London Home has acquired from the testimony of numbers who have been treated successfully for various disorders within its walls, and who have given us abundant evidence of the care and kindness which they have met from you.

Our interest in the patients will continue undiminished, but we feel it right to state openly the impressions we derive from the action of a Society which we respect as a powerful exponent of medical feeling and opinion.—We remain, sir, your obedient faithful servants,

THE CLERGY VISITING THE HOME.

To I. B. Brown, Esq., London Home.

DEATH FROM CONGESTION OF THE BRAIN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In examining a splendidly developed child, aged about four years, who died of congestion of the brain, all the other organs being healthy, I found only one kidney, which was in its proper situation and perfectly normal, but weighing three ounces and three drams. The supra renal capsule was not weighed, but appeared to be of the usual relative proportion to a kidney of that size. There was no rudimentary kidney or blood-vessel on the other side. The child was very quick, but suffered frequently from brief attacks of headache.—Yours truly,  
ALBERT HIND.

LITHOTOMY AND LITHOTRITY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am directed to inform you that, during the year ending December 31, nine cases of stone in the bladder were admitted into St. Peter's Hospital.

The children, four in number, were lithotomised, and the adults, five in number, were operated on by lithotripsy.

The result was in every case successful.—I remain, sir, your obedient servant,  
J. CÆSAR, Secretary.

MR. BANON'S RECENT CASE OF OVARIOTOMY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—At the last meeting of the Surgical Society of Ireland I detailed the particulars of a case in which ovariectomy was performed by me under peculiar and very unpromising conditions. The patient having progressed up to the time of my communication much more favourably than we could have hoped for, we began to entertain some hopes of her ultimate recovery, but, unfortunately, the result in the end proved unfavourable, she having died on the evening of the 13th day after the operation, most unexpectedly. She had progressed steadily, as far as we could judge, up to within an hour of her death, had taken plenty of nourishment with enjoyment, and complained of no pain; pulse had come down, and she enjoyed plenty of sleep. The tympanites, however, annoyed her a good deal, and resisted all our endeavours to remove it. About an hour previous to her death the breathing all at once became hurried, the pulse irregular and indistinct, and she sank into a state of syncope, from which she never rallied. On a post-mortem examination the intestines were pale, but adherent, slightly, partly to the first wall of abdomen and to each other, evidently from the effects of a low form of peritonitis. There was no serum, and but slight traces of lymph anywhere to be seen; the uterus and right ovary healthy; no trace of ligatures placed on pedicle could be found. The wound made during operation completely healed in all its parts.

The stomach and colon, however, were found to be enor-

mously enlarged and distended with flatus, and literally occupied two-thirds of the left thoracic cavity, seriously pressing on the left lung and heart, and it is to the interference thus produced on the functions of these organs that I attribute the immediate cause of death. Whether this patient would have ultimately recovered were it not for this unfortunate complication, it is of course difficult to say, but having just reached the 14th day with daily improving symptoms it is difficult to account for the sudden mode of death, otherwise than as I have attempted to do. It will be recollected that the operation was undertaken to relieve the most urgent sufferings of this poor girl, which, in the opinion of all who saw her, must have proved fatal to her in a very few days. I therefore believe that the operation performed in her case cannot be looked on as wholly unsuccessful, having been the means of not only prolonging her life, but of relieving her from the most agonizing sufferings.—I have the honour to be, sir, your obedient servant,  
A. BANON, M.D.

### THIRD REPORT

## ON THE PROGRESS OF PHARMACY, SUBMITTED TO THE BRANCH MEDICAL COUNCIL (IRELAND),

By WM. DANIEL MOORE, M.D. Dub., et Cantab., M.E.I.A.,  
EXAMINER IN MATERIA MEDICA, PHARMACY, AND MEDICAL JURISPRUDENCE,  
IN THE QUEEN'S UNIVERSITY OF IRELAND.

(Continued from page 328.)

#### A NEW TEST OF THE PRESENCE OF IODINE IN FLUIDS.

M. LARONDE proposes, in the number of the *Journal de Pharmacie et de Chimie*, for May, 1866, p. 356, a new test of the presence of iodine in fluids. Put into a test tube 10 grammes, for example, of the fluid to be analysed, with one gramme of oil of petroleum. Shake well together, and add nitric acid, drop by drop, until all coloration ceases to be manifested. Then let two drops of solution of chloride of lime fall in, and shake the mixture briskly. The oil of petroleum rises to the upper part of the tube, carrying with it in solution all the iodine contained in the liquid, and acquiring thereby a more or less intense rose colour.

#### JALAP.

The number of the same journal for February, 1866, p. 107, contains a notice of an essay upon *Jalap*, by M. Andouard, which was "crowned" by the Société de Pharmacie de Paris. It appears to me, however, that the article in question contains nothing to which it is specially necessary to call the attention of the Council. In connexion with this subject, I may note the appearance of a paper by H. Spigatis, in the *Annalen der Chemie und Pharmacie*, for July, 1866, p. 41, upon Turpeth Resin, the product of the *Ipomœa Turpethum*, one of the convolvulaceæ indigenous in Ceylon and on the coast of Malabar, and which was, it is said, employed in the middle of the 18th century, under the name of *Radix Turpethi*, until displaced by *Jalap Root*, and which has again come into use as a constituent of a secret remedy, much approved in France, the purgative drink of le Roy.

The *Bulletin general de Therapeutique* for 15th January, 1866, p. 24, contains a description of the *Solanum paniculatum* or *Jurubeba* as it is called in Brazil, which is lauded as a more energetic tonic and deobstruent than any contained in the *Materia Medica*.

Buchner's *Repertorium*, Band xv., 1866, contains, at page 4, under the head of *Phytological* contributions, a long article by Dr. August Vogel, upon *Kamela*.

A paper on *Mastich*, by F. A. Flückiger, may be found in the *Repertorium*, Band xiv., p. 309.

#### METHOD OF PREPARING MUSK FOR INTERNAL USE.

M. Sailer (*Journal de Pharmacie et de Chimie*, April, 1866, p. 291) recommends the following method of preparing *Musk* for internal use:—Rub the musk with a few drops of boiling water, then with a larger quantity, and add this solution to the vehicle prescribed by the physician, whether this be mucilaginous or not.

"By cooling, the musk partially loses, it is true," observes the writer, "its solubility; but it is then precipitated in the form of a very fine powder, and, mixing easily with the liquid when shaken, it may be taken by the patient without remaining in the mouth, as is the case with mixtures prepared with cold water. By this process, which in no way alters the qualities of the musk, it is not necessary to have recourse to the

mucilaginous vehicle generally recommended to facilitate its suspension."

#### CHARCOAL PENCILS TO REPLACE THE ACTUAL CAUTERY.

In the May (1866) number of the same journal, p. 358, is a form for *Charcoal pencils to replace the actual cautery*, recommended by M. Bretonneau:—"Light powdered charcoal, 20 parts; nitrate of potash, 1½ parts; gum tragacanth, 5 parts; water, 24 parts; and make a pillular mass, to be divided into cylinders of the size of an ordinary pencil, and about 10 centimètres (nearly four inches) in length."

In the *Annalen der Chemie und Pharmacie* for July, 1866, p. 62, is a long chemical paper by Carl Bulk, of Netphen, upon *Crotonic Acid*, a constituent of croton oil.

M. J. Léon Soubeiran contributes to the *Journal de Pharmacie et de Chimie* for March, 1866, p. 161, a description, illustrated with woodcuts, of the mode of manufacturing cod-liver oil adopted in Norway.

#### NEW FACTS RELATING TO FIXED OILS.

In the May number of the same journal, p. 332, is a paper by Mr. J. Nickles, entitled "*New Facts relating to fixed Oils.*" The author states that oil of sweet almonds (which, he informs us in a note, is made, by preference, from bitter almonds, on account of the facility of disposing of the residue to perfumers for use in the preparation of almond paste), is commonly adulterated with a cheap oil called oil of apricots. This and other adulterations are, we are told, easily detected by the reaction described in the following propositions:—

"1. At a temperature below 212° F., hydrate of lime in powder is without action on colza oil, olive oil, and oil of sweet almonds.

"2. With other oils, and especially with oil of apricots and castor-oil, this hydrate gives rise to a coagulum more or less thick, soluble in warm fixed oils, but separating on cooling.

"3. This coagulum may be isolated by filtration; so that it is possible to free from oil of apricots the more expensive olive and almond oils.

"4. The said coagulum is produced, even when the non-coagulable oil contains only about one hundredth part of oil of apricots."

#### OPIMUM.

On the subject of *Opium* I have references to five several papers. The first, by M. Deschamps, to be found in the *Bulletin general de Therapeutique*, 30th November, 1865, p. 452, relates to the "Black Drop" formerly so much in use in this country. The author, after many experiments, comes to the conclusion that nothing is known respecting its composition. A formula for its preparation appears in the new edition of the French *Codex*, just published.

The second, contained in the *Journal de Pharmacie et de Chimie*, for May, 1866, p. 386, is on the physiological and therapeutical action of *Narcein*. According to Dr. Liné, this alkaloid possesses in the highest degree the dormitive property of opium, in addition to which it is said to have certain advantages:—1. Of producing only in a very slight degree, or not at all, the phenomena consecutive to sleep obtained by means of morphia and its salts—headache, discomfort on awaking, tendency to syncope; 2. Of not confining the bowels, but rather facilitating their action—in large doses it occasions diarrhoea; 3. It produces more or less decided retention of urine, leading the author to suggest its use in children affected with nocturnal incontinence of urine. This opinion is corroborated by that of M. Ozanam, who attributes to this principle a particular action on the lumbar portion of the spinal cord.

The third paper, which appears in the *Bulletin general de Therapeutique*, 30th May, 1866, p. 444, is also on the medical use of *Narcein*. Dr. A. Eulenburg assigns its dose as ranging, for internal use, from  $\frac{1}{8}$  to  $\frac{1}{4}$  grain, and for hypodermic employment from  $\frac{1}{8}$  to  $\frac{1}{4}$  grain. The price of *narcein* is still rather high, the cost of one grain being 70 centimes, or 7d.

#### MECONIC ACID.

The fourth essay, in the number of the *Annalen der Chemie und Pharmacie* for May, 1866, p. 191, is on the reduction-products of *Meconic Acid* and its derivatives.

The fifth, in the *Bulletin general de Therapeutique* for 30th June, 1866, p. 529, is on the antagonism of opium and belladonna.

The number of the same Journal for 15th May, 1866, contains, at page 411, a paper by M. Amédée Vée, upon *Pepsin* and its preparations.

#### RHEADIN.

O. Hesse has discovered in the capsules of the *Papaver Rheas*, a new alkaloid, which he calls *Rheadin*. In the cold

it is in a short time decomposed by the most different acids, the solution becoming of a beautiful purple red colour; while the alkaloid, which was at first colourless, is converted into a brown amorphous mass. Rheadin exists also in the better kinds of opium, though it is not to be obtained in a pure state from them. Buchner's *Repertorium*, Band xv., No. 3, 1866, p. 139.

## SANTONIN.

M. Méhu contributes to the *Journal de Pharmacie et de Chimie* for April, 1866, p. 272, a "chemical and physical study" upon *Santonin*. He finds that red, yellow, orange, and green glasses prevent the yellow coloration of this principle, while blue and violet glasses excite it. Unlike erythrocin-taurine and red phosphorus, santonin coloured yellow by light is not restored to its colourless condition by heat, but only by the action of solvents. Santonin rendered yellow by light has its point of fusion lowered from 338° to 311° F.

Professor Dr. C. D. Schroff contributes a long paper upon *Scull* to Buchner's *Repertorium*, Band xv., 1866, Nos. 4 and 5, p. 181.

The *Annalen der Chemie und Pharmacie* for May, 1866, p. 190, contain a short note on *Scoparin*, the crystallized yellow colouring matter of the *Spartium Scoparium*, first described by Stenhouse.

At page 230 of the same may be found a paper by W. Lossen, upon *Atropia*, too purely scientific to require notice here.

## LIQUOR ARSENICALIS.

In the *Journal de Pharmacie et de Chimie* for April, 1866, p. 291, is a notice of a proposal, by M. Hager, of a plan for greatly facilitating the preparation of the *Liquor Arsenicalis*. The peculiarity of M. Hager's method consists in not adding all the water at once. He introduces into a glass tube, well dried to prevent the arsenious acid adhering to its sides, the powdered arsenious acid, and afterwards the carbonate of potash; the tube is shaken a little to mix the two substances; a few drops of the water are added; the tube is heated in the flame of a spirit lamp; the two salts melt very rapidly, and, by ebullition with the rest of the water, the solution is complete.

## LIQUOR ATROPIÆ.

Sir William Wilde finds the instillation of the *Liquor Atropiæ* of the British Pharmacopœia to cause great pain. Is this due to the quantity of spirit present? Sir William some years ago (*Dublin Quarterly Journal*, vol. ii., November, 1846, p. 553), recommended the use of solutions containing, respectively, 1, 2, and 3 grains of atropia to the drachm of distilled water—one drop of Dilute Nitric Acid was added to dissolve the alkaloid, with 3 drops of Rectified Spirit to make the solution keep.

Sir William informs me that he now uses a solution of sulphate of atropia, which keeps long enough without the spirit.

In preparing the *Liquor Strychnici* I found it necessary to rub the Strychnia with the acid alone in the first instance, and subsequently to add the water and spirit. Made according to the Pharmacopœia, the alkaloid did not dissolve.

The *Bulletin general de Therapeutique* for 30th November, 1865, p. 433, contains a paper on the preparation, properties, and therapeutical uses of the permanganate of potash.

M. Filliol contributes to the *Journal de Pharmacie et de Chimie* for July, 1866, p. 22, a paper on the preparation of medical tinctures. The author, believing that many vegetable principles undergo changes even in alcoholic solution, urges the necessity of preparing tinctures only in small quantity, and thinks that the active principles may be preserved better in dried leaves, flowers, &c., than in the form of tincture. Extensive observation would, in my opinion, be required to establish his views, so contrary to those generally entertained.

## CATECHU LOZENGES.

At a meeting of the Dublin Chemical Club, held on the 7th June, 1866, Dr. Frazer objected to the introduction of Capsicum into the *Catechu Lozenges* of the British Pharmacopœia, on the ground that to many persons who might require the astringency of the catechu the stimulus of the Capsicum might be objectionable. He recommended a lozenge of sugar, gum, pale catechu and cinnamon. It would probably be better to have a separate form for a capsicum lozenge.

## OINTMENT OF IODIDE OF POTASSIUM.

M. Mohr proposes to prevent the brown discoloration of *Ointment of Iodide of Potassium* by adding hyposulphite of Soda to the ointment. Six grains would be about the propor-

tion of the hyposulphite for 64 grains of Iodide.—*Journal de Pharmacie et de Chimie*, October, 1865, p. 319.

The same Journal copies, p. 318, from the *Pharmaceutical Journal*, Messrs. Draper and Whitla's proposal to prepare *Vinum Ferri* with ammonio-citrate of iron, 10·5; citrate of ammonia, crystallized, 3·9; sherry, 500.

Valerianate of Quinia is rather frequently used. Would it be well to introduce a form for it? The new French Codex has one.

## SENNÆ LEAVES.

Professor Dragendorff, of Dorpat, contributes to Buchner's *Repertorium*, 1866, Nos. 6 and 7, p. 275, a paper on "the active principle and some other constituents of *Senna Leaves*;" the latter including a saccharine substance, to which Hr. Kubly gives the name of Cathartomannite.

## THE FRENCH CODEX.

While transcribing this Report I received the new edition of the French Codex, the appearance of which, after a lapse of twenty-nine years, deserves mention in a Report on the Progress of Pharmacy, notwithstanding that the introduction of such a preparation as the *Syrupus de Limacibus* into the British Pharmacopœia would justly be considered retrograde. The editors have aimed at giving to their work more or less of an universal character; accordingly, it contains a great number of preparations—for example, it has at least 65 syrups against 15 in the British Pharmacopœia, while the 75th and last chapter is devoted to a selection of formulæ from principal foreign Pharmacopœias. The inconvenience is pointed out of having in two adjoining countries, designated under the common name of Syrup of Hydrocyanic Acid (*Sirop d'Acide cyanhydrique*), a medicine which in Belgium contains 4 milligrammes of its powerful active principle; while in France it contains, according to the new Codex, 10, and did contain, according to the old, 17 milligrammes in the tablespoonful (20 grammes). This inconvenience the editors have sought to lessen by diminishing the difference between the two preparations; while, with respect to Laurel Water, they have completely assimilated the French to the Belgian formula.

## Medical News.

ROYAL COLLEGE OF SURGEONS, LONDON.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Court of Examiners, on the 16th inst., and when eligible will be admitted to the pass examination:—

Messrs. Edward Elphick, J. F. Chittenden, A. A. Thomas, J. T. Jones, John Phillips, Frederick Robertson, R. Bowen Hogg, George W. Shipman, W. Eberton Saunders, George Bradley, and John Tuck, students of Guy's Hospital; Charles E. Little, Thomas C. Thornicroft, W. Prideaux Adams, W. H. Montgomery Smith, and Edward H. Hugo, of the Charing-cross Hospital; Walter Rosser, E. Allan Waterworth, William Harris, Henry Harris, and James Tompsett, of St. Thomas's Hospital; John G. Colborne, H. Adney Bale, James Charlesworth, and Thomas E. Clarke, of the Middlesex Hospital; Andrew Boufflower, J. Pennock Sleightholme, and Charles F. Rigg, of the Manchester School; Thomas Briscoe and William Bishop, of University College; William Little, of King's College; J. De Vere Hill, of Liverpool, and John W. Wood, of St. Bartholomew's Hospitals.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a meeting of the Fellows held on the 15th instant, James Alderson, M.D., Oxon, F.R.S., was elected president of the College.

At the same meeting the following gentlemen, having undergone the necessary examination, were duly admitted members of the college:—

Frederick Simms, M.B., London, 46, Wimpole-street; Charles Gainer, M.D., Pisa, St. Remy de Provence, France; William Matterson, M.D., St. Andrew's, York.

Also, at this meeting, the following gentlemen, having undergone the necessary examination, and satisfied the college of their proficiency in the science and practice of medicine, surgery, and midwifery, were duly admitted to practise physic as licentiates of the College:—

James Goodridge Anderson, St. Mary's Hospital; William Jones Williams, M.D., Edinburgh, 32, Grafton-street East; William Alexander Slater Roysds, 23, Pentonville-road; Francis Rhodes, M.B., Glasgow, Withington, near Manchester; Joseph Moore, M.D., McGill College, Toronto, Canada West; Herbert Chrippes Upton, Petworth Park, Sussex; Newton Ramsey Colter, M.D.; Harvard, Canada; William Alesert Richards, 42, Carey-street, Henry Morris, 15, Merrick-square, Southwark; Frederick William

Young, University College Hospital; Charles Marchant Jones, Amoy, China; James Nicholls, M.D., St. Andrew's Chelmsford, Essex; Walter Bayne Geikie, M.D., Victoria College, Aurora, Canada West.

The following gentlemen were reported by the examiners to have passed the primary examination for the licence:—

Charles Aldridge, Leeds; Henry Trentham Butlin and Thomas Smith, St. Bartholomew's Hospital; James Charlesworth, Middlesex Hospital; Robert Harris, Guy's Hospital; William Kipling and Baron Alfred Rugg, University College; James Ryall Rouch, 180, Strand; John Pennock, Sleightholme, Manchester; Leonard Smith, St. George's Hospital.

**KING AND QUEEN'S COLLEGE OF PHYSICIANS, IRELAND.**—The following gentlemen obtained the Licence in Medicine during January, February, and March, 1867:—

W. A. Attwood, London; T. S. Cogan, Dublin; G. L. Griffin, 5, Charleston-road; W. G. Grimshaw, 13, Molesworth-street; W. J. Hepburn, 26, Arran-quay; G. C. Irving, 68, Morehampton; S. Kellett, Virginia, Co. Cavan; E. A. Mullins, Ennis; A. O'Flynn, Sligo; J. H. Scott, Dromore.

The following gentlemen obtained the Midwifery Diploma during the same period:—

W. A. Attwood, T. S. Cogan, G. L. Griffin, G. C. Irving, S. Kellett, J. H. Scott.

**UNIVERSITY OF EDINBURGH.**—The half-yearly meeting of the General Council of Edinburgh University was held on Tuesday week, Principal Sir David Brewster presiding. Mr. Gilbert was elected Secretary, in the room of the late Mr. Alexander Smith. The General Council having at the last meeting represented to the University Court the propriety of memorializing Government to assign one representative to the University of Edinburgh in the event of any measure of Reform being introduced, the deliverance of the Court was now read, to the effect that the Court had memorialized Government and petitioned both Houses of Parliament in terms of the representation of the General Council. The Rev. K. M. Phin, Galashiels, moved that the Council should also itself take action in the matter at the present favourable opportunity. The University of Edinburgh presented a constituency of upwards of 2,000, which was capable of being increased to 2,500. It had a larger constituency than the three other Scottish Universities put together, which might also be considered entitled to one representative. It had a larger constituency than Trinity College, Dublin, which had two members, and in point of numbers had a better right to one member than the Universities of Oxford and Cambridge had to two. Professor Christison seconded the motion, and it was resolved to transmit the petition for the House of Lords to the Duke of Buccleuch, and the petition for the House of Commons to Mr. Moncreiff, M.P. The Council then took into consideration the report of a committee on certain proposed changes on the course of study in Arts. The proposal was that it should be optional to the candidate for a degree in Arts to omit one of three classes in mental science—namely, moral philosophy, logic, or rhetoric, and to take in lieu one of the following classes in physical science—namely, chemistry, physiology, natural history, political economy, or botany. The report elicited so much difference of opinion and so strong opposition that it fell to the ground. A letter from a committee of the General Council of St. Andrew's University as to the institution of a general competition among the Scottish Universities for honours in Arts, or alternatively the foundation of open scholarships, was referred to a committee. The meeting then adjourned.

**HEALTH OF THE METROPOLIS.**—The Registrar-General, in his weekly return, states: In the week that ended on Saturday, April 13, the births registered in London and twelve other large towns of the United Kingdom were 4383; the deaths registered, 2996. The annual rate of mortality was 25 per 1000 persons living. In London the births of 1048 boys and 1057 girls, in all 2105 children were registered in the week. In the corresponding weeks of ten years, 1857-66, the average number, corrected for increase of population, is 2157. The deaths registered in London during the week were, 1372. It was the fifteenth week of the year; and the average number of deaths for the week is, with a correction for increase of population, 1481. The deaths in the present return are less by 109 than the estimated number. The deaths of five persons who were killed by horses or carriages in the streets were registered. The annual rate of mortality last week was 23 per 1000 in London, 30 in Edinburgh, and 35 in Dublin; 18 in Bristol, 22 in Birmingham, 28 in Liverpool, 29 in Manchester, 29 in Salford, 22 in Sheffield, 23 in Leeds, 17 in Hull, 25 in Newcastle-upon-Tyne, and 34 in Glasgow. The rate in Vienna

was 34 per 1000 during the week ending the 6th inst., when the mean temperature was 4.9 deg. Fahrenheit lower than in the same week in London, where the rate was 25.

The researches of Dr. Le Fort on the subject of childbirth in the principal countries of Europe show that out of 888,312 accouchements in public hospitals and institutions, there occurred 30,594 deaths; out of 934,781 accouchements at home there were only 4405 deaths. That is to say, 1 death in 29 of the cases delivered in public institutions, and only 1 in 212 of those attended at their own homes.—*London Review.*

#### NOTICES TO CORRESPONDENTS.

Communications to the London Editor should be addressed to 20 King William-street, Strand; to the Edinburgh Editor, at MacLachlan and Stewart's, South Bridge; and to the Dublin Editor, at 3, Lincoln-place.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Perhaps Dr. Chapman, through your journal, would kindly inform the Profession as to the length of time which is required during each application of the ice-bag to the spine in cases of epilepsy?

The want of this information detracts seriously from the practical value of his deeply-interesting communications.

Anxiously awaiting a reply, I remain, dear sir, very faithfully yours,  
AN IRISH PHYSICIAN.

#### ERRATA.

The report of Dr. Darby's remarks upon cholera at the Medical Society of the College of Physicians, as it appears in our last, conveys the reverse of what he intended to express—"take any other disease that was an epidemic, scarlatina or typhus fever for example, and if they excluded all malignant cases," &c., &c. What Dr. Darby intended to say was this—"and if they excluded all the milder cases, and recorded none but the most malignant forms of these diseases, they would see what an alteration would be made in the average of mortality!"

## PARALYSIS: CASES ILLUSTRATIVE OF A NEW METHOD OF TREATING IT BY THE APPLICATION OF COLD OR HEAT ALONG THE SPINE.

By JOHN CHAPMAN, M.D., M.R.C.S.,

PHYSICIAN TO THE FARRINGTON GENERAL DISPENSARY.

[Read to the Harveian Society of London, April 4, 1867.]

The term paralysis denotes in reality various diseases, diseases which differ alike from each other in respect to their phenomena, the parts of the nervous system in which they are seated, and the nature of the morbid condition which obtains. In fact, they differ from each other so decidedly that their only common element consists in disorder of some part of the nervous system, disorder most frequently, however, extending to the voluntary or involuntary muscles, or to both, at the same time. The morbid states of the nervous system are also due to widely different, and not seldom indeed to quite opposite, proximate causes—as, for example, anæmia, hyperæmia, congestion, inflammation, red softening, white softening, hæmorrhage into the nervous centres, pressure of tumours, tubercle, cancer, and finally, blood-poisoning—as in cases of syphilis, uræmia, plumbism, and the eating of bread containing the ergot of rye. There are also the cases of paralysis resulting from mechanical injuries, and finally the progressive paralysis of the insane. In fact, it seems to me that the nomenclature of so-called paralytic diseases is extremely defective; for at present it is customary to designate morbid states of the muscular system which are exactly opposed to each other in nature by one and the same word. The flaccidity and atrophy characteristic of the muscles in cases of wasting palsy, present a complete contrast to the rigidity and comparatively undiminished bulk of the muscles in other forms of motor paralysis scarcely less notable. It is impossible, therefore, to treat of this group of diseases, the members of which are so diverse, except by considering them separately and in detail; on the other hand, it is no less impossible within the limits assigned to this paper to accord to each member of this group special consideration. Moreover, in inviting the attention of this Society, as I am about to do, to a new method of treating paralytic affections, it seems to me that it will be most satisfactory, instead of dealing with the subject in its most generalized aspect, to offer certain concrete and detailed illustrations of the principles and method in question, for by doing so, I shall, I believe, best facilitate an adequate comprehension and due appreciation of those pathological and therapeutical doctrines which I advocate. I shall, therefore, at once ask your attention to the particulars of a

1.—*Case of Paralysis involving the muscles of the tongue, throat, back, and four extremities, and associated with giddiness, headache, profuse dribbling of saliva, constipation, and scantiness of the menses, treated chiefly by the application of cold along the spine.*

Mrs. P., aged 42, a thin, nervous, and intelligent person, married, and has a son 19 years old, was first seen by me March 30th, 1863, when I wrote the following description of her condition: She is speechless, her head falls forward on her bosom, and her four extremities are paralysed. She cannot utter any distinct articulate sound: a stranger can understand nothing, or next to nothing of what she tries to say, although those who are constantly with her can make out much of what she means. The tongue is atrophied and shrivelled; its surface is wavy or corrugated, as though not lessened in proportion to the muscular substance. The organ is very tremulous when an attempt is made to put it out, and the tip of it cannot be protruded beyond the teeth. Saliva dribbles continuously from the mouth both night and day. The patient has great difficulty in swallowing: it is with considerable effort that

she swallows solids, and, when she does so, she makes a peculiar noise; she can take fluids in only very small quantities at a time, and she usually spills a part of anything she attempts to drink,—“it comes back,” as her nurse says. The muscles of the face, neck, and of the whole back are extremely thin and wasted. There is often, and very distinctly, observable in the muscles of the back, that remarkable quivering characteristic of wasting palsy, and which reminds the patient's nurse, as she says, of “sheet lightning in a summer evening.” The whole back is remarkably hot. The arms and hands are almost powerless: the right arm can, however, be raised until the elbow is as high as the mamma; and the left can also be raised so far as to enable the tips of the fingers to reach up as high as the eye. The whole upper extremities, but especially the forearms and hands, are extremely wasted. The common extensors of the fingers are almost wholly paralysed; the extensor indicis retains some power, but it is very weak. The extensors of the right thumb retain considerable power; those of the left are quite paralysed. The long flexor of the right thumb is absolutely powerless; there are, however, in place of the thenar eminence a few—very few—fibres by which the thumb is slightly moveable. The long flexor of the left thumb has still some power, but the short muscles on this side are wholly gone. In place of the ball of the thumb on each side there is a deep concavity. The fingers are slightly flexed, and the first phalanges being drawn backwards, the hands assume somewhat the appearance of birds' claws. The sensibility of both hands is normal. The thighs, which are slightly flexed on the trunk and powerfully adducted, are nearly immovable, so that when the patient is seated she cannot prevent herself from slipping gradually out of her chair. The fore-part of each foot is bent downwards, and firmly fixed in that position; the left foot is also so drawn that the toes and sole turn inwards. The toes of both feet are slightly mobile; but the feet themselves cannot be moved from their abnormal positions by applying even a considerable amount of external force. The muscles of the lower extremities are not notably wasted. The patient has experienced, she says, much giddiness, especially when standing up, during the whole period of her illness, and not unfrequently suffers from headache. The appetite is much impaired; the bowels are habitually constipated; and the catamenia, though regular, are very scanty.

About three months before she became ill she fell down on her left hand, and forced the middle finger backwards, but without breaking it; she almost fainted with the pain. The finger got fairly well, but always remained very weak, the power of flexing it continuing slight. About two years and a-half ago this finger became more markedly weak, and ultimately paralysed. The paralysis then extended to the corresponding thumb, and in May, 1861, her limbs began gradually to lose power. The left arm, then the left leg, then the right arm, and then the right leg being successively involved. The quivering of the muscles began, the patient says when her illness began, and was first perceived in the legs, especially in the left thigh, then in the muscles of the back, then in both arms, and particularly in the left upper arm and the shoulders; it was next experienced on the left side of the face, then over the face generally; and, finally, as she states, in the soles of the feet. “When at the Middlesex Hospital, I felt,” she says, “as if my back and legs were all alive.”

She became an in-patient of Middlesex Hospital in May, 1861, she was afterwards treated at the National Hospital for the Paralysed and Epileptic, then at a dispensary, and finally by two medical men successively, who attended her at her own house.

When first prescribing for her, I ordered aperient pills to be taken occasionally at bed-time, quinine and sulphuric acid twice a-day, and requested that the shoulders, arms, back, and legs, should be rubbed vigorously as often as practicable, and that towels dipped in iced-water, and so folded lengthwise as to be about four inches broad, should be applied along the whole spine during twenty minutes, three times a-day—the towels being carefully

changed immediately they became warm. This report would become inconveniently long were I to give a detailed account of the treatment I adopted during the time the patient was under my care, I shall therefore restrict my description of it to a general statement of it as follows:— Besides the medicines just named, the only others used were calumba, citrate of iron and quinine, nitric acid, an aperient draught, and bicarbonate of potash. Galvanism was applied to the muscles—chiefly of the extremities, and was used for the first time, May 15, 1863. I also applied heat freely, by means of hot water, to the extremities; but the maintreatment, and that upon which I principally depended, consisted in lowering the temperature of the spinal region, by means sometimes of iced-water, sometimes of the spinal ice-bag. The applications were, at one time, along the whole spine, at another to a part, and for different lengths of time, the variations being made according to indications observable from time to time.

*Results of Treatment.*—The patient showed indisputable signs of improvement within the first week of treatment, which was continued upwards of two months, during which she progressed most encouragingly. Up to the end of that time the change effected in her may be summed up as follows:—She could hold her head erect; could protrude the tip of the tongue beyond the teeth full half an inch; the dribbling of saliva quite ceased; she could speak much more distinctly; could swallow fluids without difficulty, and drink a cupful of tea or coffee at a draught without becoming choked, or spilling any of it; she could raise the right arm vertically—placing the elbow higher than the head, and the left arm so that the tips of the fingers reached as high as the top of the head; the arms increased in size,—during the first eighteen days of May the diameter of the middle of each forearm increased a quarter of an inch; and the power of each arm was correspondingly increased. Even as early as the 18th of April, she said:—“My arms are wonderfully much stronger. I can feed myself; can pull myself up, and can wipe my face, &c.,” and with joyous pride showed me that she could lift a chair—a feat she could not perform the previous week. The claw-like set of the fingers disappeared. On the afternoon of Sunday, May 3rd, the patient experienced a sudden increase of power in the extensor muscles of the left forearm, where, for the first time, I could distinctly feel their contractions beneath my fingers; and the pulling and grasping power became, during the treatment, markedly greater than before. The concavities formed by the wasting of the ball of each thumb, were in no perceptible degree filled up; there was, however, a slight though decided increase of motility of each thumb, and the left flexor longus pollicis became markedly stronger, notwithstanding that the concavities just named continued. The metacarpal inter-osseous spaces of each hand were gradually filled up to a surprising extent, so much so, indeed, that her hands became quite plump. The power of flexing the thighs on the trunk and of separating them from each other gradually returned, so that instead of slipping down from her chair continually, as she had formerly done, she was able to maintain her position, and, finally, to move her thighs about freely in all directions. The feet gradually became susceptible of passive motion, and afterwards she was capable of putting both feet flat to the ground, and of moving them in different directions—outwards as well as inwards—by the mere force of her will. During the latter end of May she stood occasionally for two or three hours at a time, supporting herself sometimes only with one hand, and one day, with the help of her son, she walked into an adjoining room. The muscles of the back, with the exception of a few of the upper fibres of the trapezius, ceased to quiver, and re-acquired a very considerable development. In fact, she gained flesh generally to such an extent as to cause her nurse to complain, during the latter portion of her attendance, of the great additional weight of the patient when moving her about. This increase of flesh was even more remarkable in the face than in the rest of the body, so that, compared with what she had been, she appeared quite plump. The back became permanently much cooler than it had been; the function of the bowels healthier;

the catamenia abundant;\* appetite greatly improved; the head clear, and not only free from headache, but free from the great giddiness, which, up to the time when my treatment began, she had experienced during the whole period of her illness.

At the end of May pecuniary and domestic troubles which had long pressed heavily upon her reached a crisis, which exerted such a depressing influence upon her as not only to stop further progress, but actually to throw her backwards. During the long period of her illness her husband, who is a working man, had been obliged to pay some one to do the house-work and to attend on her, and having become involved in debt he now sent away the person who had done this work, and broke up his house. His wife was then taken to her relations, at her native place in the country, and I never saw her again.

It would be difficult, indeed almost impossible for me, to select a case more suitable than this to exemplify the efficacy of the therapeutical method, which consists in modifying the temperature of the spinal region; for this patient presented a combination of symptoms, each of which may be fairly regarded as a grave disease, and each of which was influenced beneficially, and to a remarkable extent: there was paralysis with flaccidity and wasting of the affected muscles; there was also paralysis with rigidity of the affected muscles; there was headache, with giddiness, especially when the patient stood up; there was profuse dribbling of saliva; there was loss of appetite; habitual and extreme constipation; and the menses were very scanty. Now it appears to me that a skilful interpretation of these various symptoms would lead to the inference, that the spinal and collateral sympathetic nervous centres were in that morbid condition, which indicated that the application of cold would exert a remedial influence. The history of the case seems to show that the disease originated by injury to the hand, that the morbid condition induced by the accident result in the transmission of a morbid influence to the spinal cord; and that this influence was diffused both along the cord, and over the sympathetic nervous centres. As might be expected, the disease was most intense in that region of the cord where it was first generated, so intense, indeed, that probably portions of the cellular constituents of that part ultimately became more or less atrophied or destroyed. Simultaneously the collateral sympathetic ganglia were kept in a state of morbid excitement by the influence of the disease in the cord, and thus exerted an excessively constricting force on the arteries under their control. In this manner, I account for the particular form of paralysis with which the muscles of the throat, neck, upper extremities, and dorsal region were affected. While, on the one hand, that healthy influence dominating the nutritive processes which is diffused from the cerebro-spinal system throughout the organism was, in respect to the parts in question, greatly diminished and probably also perverted, and while the power of transmitting motor impulses to the muscles implicated was impaired, the supply of blood to these muscles was so greatly lessened, owing to the chronic spasm of the arteries distributed to them, that it was no longer possible for them to receive adequate nourishment. The conditions here described are precisely those which are calculated to insure muscular atrophy; and, I venture to suggest, that that peculiar feature which frequently distinguishes wasting palsy, viz.,—the wasting of special groups of muscles, and groups, moreover, which are often related to each other by co-ordinate action, originates in the fact that special series of nerve cells occupying limited areas within the spinal cord, and functionally related to the group or groups of muscles implicated, are diseased, the rest of the cord remaining healthy, or at least disordered only to the extent of hyperæmia. In this case the result of the diffusion of the morbid influence down the cord and to the collateral sympathetic centres was, as it seems to me, the production in those

\* They became so for the first time on May 3rd, when she said—“I feel that the change is doing me good.” It was at this date that she experienced the sudden increase of power in the extensor muscles of the forearm.

parts of hyperæmia, so considerable as, by greatly intensifying their functional energy, to induce a tetanoid condition of the lower extremities: the energy of the spinal cord transmitted to them was continuously excessive, thus inducing in them a state of continuous contraction. Simultaneously the stimulus diffused from the sympathetic ganglia over the arteries of the lower extremities, so far exceeded the normal amount, as to lessen in some degree the supply of blood to the muscles, and thus insured the condition which, as is well known, is peculiarly favourable to the onset and continuance of spasm or muscular rigidity. On the other hand, while the nervous centres related to the arteries in question were so far unduly active as to produce the condition just described, they were not acting with that intense degree of morbid energy which would result in almost wholly cutting off the blood supply, and which, as stated, was the case with respect to the nervous centres related to the upper part of the body. Hence, while the muscles of that part were extremely wasted, some of them being almost wholly destroyed, the muscles of the lower extremities were not diminished to any considerable extent.

If it be admitted, as indeed it must be by all who have experience in this matter, that the cerebral blood-vessels are under the government of nerves emerging from the sympathetic within the region limited above by the fifth or sixth cervical vertebra, and below by the third or fourth dorsal, and if it be further admitted that in the case in question the sympathetic centres within this region were morbidly affected, we should be led to predict that the cerebral circulation would become disordered, and that the disorder itself would present the form of cerebral anæmia. This, in fact, was the case: there was headache, associated with feeble mental action, and frequent giddiness, especially when the patient stood up.

Seeing that there were symptoms of grave disease of the spinal cord in that region where the nerves to the upper extremities are given off, it is easily intelligible how the uppermost part of the cord, together with the medulla oblongata, would, through the propagation of the morbid influence upwards, become hyperæmic. Now the nerves which cause the parotid and submaxillary glands to pour out their appropriate secretion, are motor-nerves from the cerebro-spinal system, viz., branches of the auriculo-temporal and the chorda-tympani, and the origin of these nerves is the medulla oblongata. These facts being recognised, it will be at once seen that hyperæmia of that nervous centre is likely to result in an excessive flow of saliva; and such in fact was the case with the patient in question.

Extensive experience has taught me that an abnormally irritable state of the spinal cord and collateral sympathetic ganglia along the lower half of the dorsal region, is peculiarly conducive to functional disorders of the stomach—loss of appetite, indigestion, nausea, vomiting. And I have long been of opinion, founded on many observations, that one at least of the immediate causes of nausea is a great superabundance of mucus in the stomach, owing to the excessive stimulus transmitted from the spinal cord to the mucous glands of that organ. Assuming my diagnosis of the case under consideration to be correct, it follows that there was hyperæmia of the whole of the spinal cord, below as well as above the part first diseased, and therefore an intelligible cause of the symptom—loss of appetite; and, as I shall now proceed to show, of the extreme and habitual constipation from which the patient suffered.

If my ideas concerning the pathology of constipation be correct, it may proceed from three causes—1st, from partial atrophy of the circular muscles of the intestines; 2nd, from inadequate nervous stimulus of those muscles; 3rd, from a deficiency of intestinal mucus. Now, as I contend (and I must content myself for the present with merely stating my conviction), both the muscles and the mucous glands derive their functional energy from the spinal cord; if so, the second and third causes just named of constipation, consist in enfeeblement of that part of the cord related to the intestines. This condition is far less frequent than that of excessive spinal irritability, the result of spinal

hyperæmia. It follows, therefore, that constipation due to spinal anæmia, and therefore enfeeblement, is comparatively rare. On the other hand, cases very frequently come before me, in which obstinate and habitual constipation is associated with indubitable symptoms of hyperæmia of the nervous centres along the lower dorsal region. In these cases the production of constipation is, I apprehend, as follows:—The nervous energy diffused over the mesenteric arteries being excessive and continuous, forces them into a state of chronic contraction, many of the smallest ones being often, I doubt not, closed entirely. The consequence is, that the intestinal muscles cease to be adequately nourished, and therefore, losing their wonted strength, become incapable of effecting those vigorous vermicular contractions on which the power of the alimentary tube to propel its contents with healthy force and regularity depends. It is conceivable, and indeed probable, that when, owing to chronic contractions of the mesenteric arteries, arterial blood is partially shut off from the intestinal walls, the mucous glands will receive less than their due supply, and that therefore, while those glands are being adequately stimulated to fulfil their functions, they are incapable, from want of blood, of elaborating a sufficiency of mucous; if so, two distinct causes may co-operate in producing the constipation in question. If these views be sound, we should be justified in predicting that, in the case just described, the character of the paralysis would be associated, as it was, with persistent constipation.

The last symptom to which I have to advert was scanty menstruation. Reasons have already been given for believing that the nervous centres in the lumbar region, as well as those above, were hyperæmic; and I have demonstrated by a large amount of evidence that, if the nervous centres along the lower half of the spine are rendered hyperæmic by the application of heat, the menstrual function may be retarded, lessened, arrested, and in some cases, at all events, completely suppressed. It will therefore be readily understood how the special menstrual disorder of this patient was one of the results of that general disease of the nervous system from which she suffered.

In seeking to understand the nature of things, it behoves us, as has been well said by Newton, to admit only such causes as are at once true and adequate to explain the phenomena in question. In what I have said concerning the foregoing case, I have alleged that one morbid state of varying degrees of intensity in various parts of the spinal cord and sympathetic was adequate to produce all the symptoms passed in review, and have attempted to explain, *seriatim*, the *modus operandi* of their production.

Of course, if my explanation of the proximate cause of the symptoms be correct, it follows that the most scientific method of removing that cause would consist in exercising a sedative influence on the nervous centres morbidly affected, and on no others. My treatment of the patient was the result of this reasoning, and considering how signally several other attempts to relieve her had failed, and the desperate state in which I found her, the benefit conferred is a striking testimony to the efficacy of the plan adopted. The medicines already mentioned, which were administered, played, I apprehend, a very subordinate part in the remedial process; the friction which I ordered to be applied to the wasted muscles with a view of facilitating an increase of their nutrition, as well as the galvanism which was applied chiefly to the lower extremities, probably co-operated more effectually; but my experience in many other cases enables me to state confidently, that the great improvement which was effected in this patient was mainly due to the application of cold along the spine.

2. *Case of paralysis (hemiplegia and paraplegia) associated with Epilepsy and inducing great impairment of speech, extreme incontinence of urine, excessive drowsiness during the day-time, and extraordinary coldness of the surface of the body, especially of the extremities, even in summer, treated by means of the spinal ice-bag.*

H. C., male, aged 56, suffering from paralysis and epilepsy, was first seen by me, June 11th, 1863. The patient

can stand by himself with difficulty, but cannot walk without support and the use of a stick. Both legs are equally weak; he can stand on neither alone. The toes of the left foot are turned inwards as he sits, and he cannot turn them outwards. His speech is greatly impaired, very thick and indistinct. There is hyperæsthesia on the left side of the face, where he feels two points two and a-half lines apart; on the right side he cannot feel two points until they are ten lines apart. The right arm is considerably weaker than the left. Both hands are numb, and have the feeling as of being pricked with "pins and needles." He feels two points at seven lines apart in the right palm, and at five lines apart in the left. He is extremely troubled by the need of making water with excessive frequency: at his best times he is obliged to urinate about every fifteen minutes; at his worst about every five minutes. The bowels are irregular, but generally costive, sometimes ("most weeks") they go three or four days without action. The patient sleeps well, as he says, at night and during a considerable part of each day. He complains that his head is heavy and dull, that he is "cold all over," and that he suffers especially from coldness of his hands and feet, even in the hottest weather: he sits close to the fire in summer. Pulse 76; pupils equal; sight good; tongue clean and straight.

He thinks he was quite healthy until he was twenty-five years old, when he had what he called a long "epileptic" fit, and went to the Middlesex Hospital a month. Had no other fit until he was forty years old, when he complained of a feeling (pressure) in his head, and immediately fell: he was much convulsed, and bit his tongue. He was unconscious about thirty minutes, and recovered completely. A few days afterwards, while sitting at tea, he suddenly dropped his knife, lost the use of his right arm and leg to a great extent—not completely; he also lost completely the power of speech, but did not lose his senses. He was bled in the arm, when his speech returned. He never recovered the full power of the right arm and leg. He ascribed this fit to depression of spirits, caused by losing his employment through the death of his master. In his forty-third year he had another fit lasting about half-an-hour, the hemiplegia not being increased. Had no other fit until his fifty-third year, when he had one, succeeded by increased paralysis of the right side. The hemiplegia and the fits have been gradually increasing, the latter recurring at intervals of a few months, and becoming more frequent, now occur about once a month; the last fit happened on the 19th ult. The patient is in great poverty, and wholly dependant on the labour of his wife, and the help of benevolent friends, who offer to supply him with ice during my treatment.

I ordered ice to be applied along the whole spine during two hours, five times during each twenty-four hours, and requested that the spinal ice-bag should be enclosed in flannel; I also prescribed five grains of bromide of ammonium twice a-day.

June 18.—Has had no fit, and does not feel likely to have one. His head feels better, feels lighter; "he don't feel," his wife says, "that heaviness that he did." Sleeps well at night and less in the day-time than before. Has not complained at all this week of the numbness in his hands: his wife says they are decidedly better. The weakness of the legs continues, and is, she thinks, greater than last week. The bowels have already become "very regular, once a day, and sometimes twice," since he began to use the ice. He retains his urine longer than formerly. Feels warm all over—the feet being especially warm.

25th.—No fit; he says the "head feels very well; feels clear and cool; I don't seem to have any fear of a fit;" the speech is clearer and more distinct; the sensibility on each side of the face is now equal; he feels two points at three lines apart round the angle of the mouth on each side; the right arm has decidedly gained in strength; and the sensibility of both hands has become normal; he now feels two points at four lines apart in each palm; the lower extremities are also stronger; he can now turn the left toes outwards; bowels regular; he notices a great di-

minution in the frequency of making water; continues constantly warm all over; to apply the ice as last ordered four times a day instead of five, and to continue the bromide of ammonium.

July 2nd.—No fit; sleeps well at night, but *much less* in the day-time than he used to do; bowels regular. He now makes water about four times during the night, and six during the day. To apply ice as before three times a day instead of four, and to enclose the spinal ice-bag in a thick worsted stocking instead of in flannel as before. R Quinæ Desulphatis, gr. i.; Acidi Sulphurici diluti, ℥ vii. bis die.

9th.—No fit; no headache; feels himself "as well as possible, but very hot—very hot;" his speech is greatly improved; his mind also; the mental improvement is clearly expressed in his face, which is lighter and more intelligent; sleeps "capital" at night, still less during the day; feels no numbness whatever of the hands and no sensations as of "pins and needles;" can still evert the left foot, and can now stand on each leg, but especially on the left one; he can also now walk alone; bowels regular; power of containing the urine continues to increase; now passes it about four times in the day and four times in the night. To apply ice twice daily, in three folds of worsted, and to continue the medicine as before.

16th.—No fit. Reports himself still better. His wife says "he does not sleep in the day like he used to do, and sleeps very well of a night." He talks still more clearly. Retains his water still better, getting up only twice, or at most three times during the night. He can now sometimes walk very well, even without the aid of a stick. To continue as last ordered.

23rd.—Has had no fit, but has just fallen, having been pulled down by his wife in her attempt to get him out of the way of a carriage, after getting out of an omnibus. He is shaken by the fall, and complained for a short time of headache afterwards. Otherwise is in all respects the same as last week. Treatment same as before.

30th.—Still no fit, notwithstanding the fall and fright last week. Yesterday, for a short time, the right hand became "rather shaky" and numb: the numbness lasted about half an hour; the shakiness a good part of the afternoon. He was quite well again in the evening. His head remained quite unaffected. The improvement of the bowels and bladder continues. To apply ice during two hours three times a day; the bag being enclosed in one fold of flannel. R Potassi Iodidi gr. iij, Ammonii Bromidii gr. v, ex aquæ ter die.

August 6th.—Continues without a fit or other bad symptom. To persist in the treatment last ordered.

September 9th.—Had a fit on the 30th ult. at 5:30 A.M. His wife says she believes "its worry that brought it on." She states that he had ice each day until the fit, but none afterwards. *Since he left off the ice he has become cold again.*

A careful consideration of the symptoms of this case, apart even from its history, can scarcely fail to lead to the conclusion that the paralysis of the extremities, the dull heavy headache, the defective speech, the disordered sensibility evinced by the cheeks and hands, the grave functional disease of the bowels and bladder, the excessive somnolency, and remarkable coldness of the surface of the body, are all referrible to excessive hyperæmia, merging into congestion of both the spinal cord and the sympathetic nervous system. According to my reading of the case, there was considerable congestion of the spinal cord, resulting in the paralysis of the lower extremities, and co-operating to produce the disordered sensibility especially evinced in the face and hands, as well as the extreme functional derangements of the bowels and bladder. On the other hand, the vascular condition of the sympathetic ganglia was rather one of extreme hyperæmia than of congestion, hence their preternaturally vigorous action which resulted in such vehement arterial contractions throughout the system as to deprive the brain, as well as the periphery of the body generally, of its due supply of blood. The consequence was, the mental heaviness and extraordinary somnolency and the excessive coldness which the patient ex-

Fig 1

Fig 2

Fig. 3

Fig 4

perienced. Moreover, other of the symptoms were not less certainly, though less obviously, due to the same cause; the anæsthesia or numbness, and the sensations as of being pricked by "pins and needles," though partly referrible to congestion of the medulla oblongata and spinal cord, were also, I have reason to believe, in a great measure due to the excessive action of the sympathetic, which, lessening the supply of blood to the parts affected, prevented that complete nutrition and oxydation of the nervous constituents of the tissues of those parts which are essential conditions of normal feeling. The same cause resulted in the starvation of the muscles of the bowels, and, probably, of those of the bladder. Hence, according to the explanation already given, the peristaltic energy of the bowels was impaired; and hence, probably, the muscular coat of the bladder, being also weakened, became abnormally irritable in accordance with the well-established fact that badly-nourished, weakly muscles are most excitable.

Assuming this pathological view of the case, it is obvious that no treatment of it was calculated to prove so beneficial as that which was capable of abolishing at once the hyperemia and congestion of the spinal cord and sympathetic; and as the case was one of many years standing, and therefore presenting, probably, extreme dilatation of the blood-vessels of the nervous centres in question, I ordered the prolonged use of the spinal ice-bag each day in the first instance, in order the more effectually to remedy the morbid condition in question, and, at the same time, to prevent the possibility of reaction.

It is extremely to be regretted that this patient was not enabled to continue providing himself with ice for a much longer period than that during which my treatment of him lasted; for had the blood-vessels of the nervous centres acted upon been kept vigorously contracted to their normal diameters during an adequately long period—say probably six months, I have reason to believe the patient would have derived greater, and more lasting benefit than was actually conferred upon him. It will be admitted, however, that the case as it stands, is an extremely interesting and instructive one, inasmuch as it affords the most decisive proofs of the truth of those pathological and therapeutical doctrines, which I have propounded. Within the space of five weeks, the right arm of the patient became much stronger; he was enabled to walk alone, even without the aid of a stick, to evert the left foot, and to speak very much more distinctly; his intelligence and mental expression were greatly improved; the numbness and other disorders of sensations, as well as his headache and drowsiness in the day time, vanished; he became not only warm all over but "very hot;" his bowels were opened daily; his power of retaining his water so increased that he was obliged to get up only twice, or at most thrice, during the night; and, finally, whereas before treatment he had an epileptic fit about every month, one did not occur until nearly three months after the treatment began.

The fact that the patient became cold again after leaving off the spinal ice-bag is both interesting and instructive: the chronically contracted arteries were dilated to their normal volumes by the treatment adopted, but not being under its influence sufficiently long to enable the newly-reacquired increase of their diameters to become established as a physiological habit, they contracted again when the spinal ice-bag was no longer applied, and hence the patient again became cold.

(To be continued.)

#### REMOVAL OF AN ENORMOUS OSSIFIED ENCHONDROMA FROM THE FACE.

By MAURICE H. COLLIS, M.B. Univ. of Dub.; F.R.C.S.I.,  
SURGEON TO THE MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY;  
MEMBER OF THE COUNCIL OF THE SURGICAL SOCIETY OF IRELAND, AND  
OF THE PATHOLOGICAL SOCIETY OF DUBLIN; SOMETIME EXAMINER IN  
SURGERY TO THE QUEEN'S UNIVERSITY IN IRELAND, AND MEMBER  
OF COUNCIL OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
ETC.

EARLY in the present year I was consulted by a gentleman, well-known in this city, with reference to a tumour, which

produced much deformity of the left side of his face. This gentleman is somewhat under fifty years of age; is of active habits, and has always enjoyed excellent general health. The history which he gave me of the gradual development of his tumour was to the following effect:—

"The first indication of the tumour on my face was a slight hard swelling on the gum just by my front teeth (left incisors), which I noticed when I was probably twelve or fourteen years of age. Since that period the swelling continued to grow steadily, but almost imperceptibly, until within the last three or four years, when it developed itself with singular rapidity, and attained such formidable proportions, that I became anxious for its removal.

"Ever since the first appearance of the tumour it was carefully watched by Mr. Adams, and frequently examined (at his request) by almost every eminent surgeon in Dublin, including the late Sir Philip Crampton, Mr. Carmichael, Mr. Cusack, Mr. Colles, Mr. Maclean, the eminent dentist, and others.

"The general opinion at that period seemed to be against an operation, on the ground that there was nothing malignant in the growth; that it never would be otherwise than harmless, and because some, including Mr. Cusack, thought ten or twelve years since that it had ceased to grow. However that may be, the fact is now undeniable that within the last ten or twelve years it has increased more than in all the previous periods.

"Some years before Sir P. Crampton's death, Mr. Adams, Mr. J. Smyly, and I were with him in Merrion-square, and he then made a puncture from the inside of the nostril into the interior of the tumour, and inserting a small tube, got out a trifling quantity of fluid, not more than a drop or two. He first endeavoured to bore through the gum, but failed, apparently from the solidity of the bone. About the same time Mr. Maclean extracted a tooth near the front (left canine), and then made some ineffectual examination with a probe, or some such instrument. I did not feel the extraction of this tooth. I may add I was always deficient by a tooth on this side. The sight of my left eye left me very gradually. It evidently went as the tumour extended, and about fifteen years ago it became completely extinct."

To this simple history of the growth I have only to add a few particulars. In the first place the tumour from the very outset was always firm and hard to the touch, showing that, at least its covering was bony; further, there was no pain either in the tumour itself or resulting from its pressure during the greater part of its progress; even the loss of the eye was so gradual as to be painless, any sensation amounting only to uneasiness. Within the last two years the tumour had grown rapidly forwards, and had distended the soft parts of the cheek; browache, with shooting pains of a dull nature were felt rather constantly during that period. Hearing on that side also became somewhat dull. The pressure on the left nasal cavity made it quite impervious. Breathing was impossible through the left nostril, nor could air be forced through it to any appreciable amount. The sense of smell was necessarily in abeyance as regards this side. Even the other nostril participated in the inconvenience, so that when the gentleman was in a warm, dry atmosphere, his comfort was much impaired by reason of a dryness and stuffiness in the nasal passages, and the immediate occurrence of ache in the frontal sinus.

Placing the patient almost in profile, and looking at him from the right side, as in the position shown in Plate I., it was observed that the tumour projected in an even curve from the floor of the orbit to the mouth, so that the prominence of the tumour extended a full inch beyond the outline of the nose. The two nostrils looked directly towards the observer, so great was the distortion of the nose. The left nostril was somewhat dilated. The outlines of the mouth were much altered, owing to the left side of the mouth being depressed, and the left side of the upper lip much distended over the lower part of the tumour. The lower lip and upper part of the chin were thrown deeply

into shadow, and also somewhat out of drawing. Upon reversing the position, as in No. 2, the great prominence of the tumour came fully into view. It occupied the whole region of the cheek, and bore upon its surface evidence of two distinct epochs of growth. If a line be drawn from the inner angle of the left eye to the angle of the lower jaw on the same side, two distinct types of growth will be noticed, the one occupying the face above, and to the outer side; the other below and internally. I shall take the former first, as it represents what, for want of a better term, I may call the more chronic condition of the tumour. We observe here a distinct elevation of the floor-line of the orbit—this is not due merely to an elevation or pushing up of the lower eyelid or other soft parts; the finger and even the eye could detect that the bony ridge itself was higher than that on the right, otherwise the bone in this spot was not altered in texture or outline—it was simply pushed upwards. On the outer side the junction of the maxillary and malar bones is prominently seen; the bones here were expanded, but the body of the malar was not altered in size—it was plain, therefore, that the disease was limited in that direction. Altogether, then, it appeared evident that there was no present active extension of the growth above or outside the line I have imagined to be drawn from the inner angle of the eye to the angle of the jaw. Within this line matters were far different. Reaching high up on the nose, almost to the angle of the eye, and to the central line, a rounded mass of bony hardness, was formed. On the inner side it passed down as far as the lower margin of the ala nasi, where it was joined by a second mass which reached far down into the mouth, and which bore upon its buccal extremity two incisor teeth. Passing outwards these two portions, separated by a fissure on their nasal aspect, became consolidated together, and formed by their union a mass of great size, still rounded in outline, and of firm inelastic nature. The growth pushed the nose out of the mesial line to an extreme degree, and extended outwards and forwards, so as to distend the soft coverings of the cheek to a huge extent. On opening the mouth it was found to have extended backwards to the palate bone, and to have pushed down the palate process of the maxillary even to a greater degree than it had pushed up the floor of the orbit. Along the alveolar ridge it had grown to a greater degree than at any other part, except towards the nose. It was evident that its progress in these directions was fast reaching the utmost limits compatible with any approach to comfort, and that a little more increase would soon threaten existence. This extension downwards, and threatened extension backwards, was likely to lead sooner or later to the filling up of the cavity of the mouth. In Hey's works will be found the drawing of such a case, where the tumour developed in this direction to an enormous amount. As it was now clear that an operation was unavoidable, I arranged to meet, in consultation, Mr. Adams and Sir William Wilde. After careful examination, and a prolonged discussion, a plan of operation was agreed to, which offered the prospect of removing all the active portion of the growth with as little interference as possible with the function of speech. The gentleman's occupation rendered this proviso essential. I was under the impression that this latter object might be attained by simply preserving the muco-periosteal coverings of the palate plate and palate bone, but in this I was overruled, and I finally resolved to attempt to preserve a thin layer of bone along with the periosteum in this locality. Before the details of the operation were conclusively arranged the eye was carefully examined by Mr. Wilson, who reported that there was hopeless disorganization of the vitreous humour, and displacement of the retina to such an extent as to show that no operation could restore sight. Blindness, in fact, resulted from the remoter effects of pressure, so that the removal of that pressure could not now restore vision. Mr. L'Estrange also examined the palate for me, and came to the conclusion that the layer of bone immediately above the periosteum was sound, and that it might safely be retained.

All things being arranged, the operation was performed,

on the 7th February, in the theatre of the Meath Hospital, in presence of a very large concourse of surgeons and students. This was due not so much to the severity of the expected operation, as to the personal popularity of the patient, who is extensively known and highly respected as a citizen of Dublin. Chloroform was administered throughout by Professor Macnamara, and during the long and tedious operation, the patient only once became for an instant partially conscious. When I state that the removal of the body of the tumour occupied twenty-seven minutes, and that during nearly half of that time I was engaged at the palate, this result was highly satisfactory.

The patient was laid upon an operating table which admitted of his head being raised to any required degree. I stood in front and to the left side, Mr. Porter close beside me, and Mr. Smyly opposite to him. I have to acknowledge most gratefully the unwearied assistance they gave me during the progress of this most trying operation. My other colleagues, Mr. Wharton and Mr. Stokes, also rendered valuable aid, and Mr. Adams and Sir William Wilde, were close at hand to assist in carrying out the plan we had agreed upon. As a preliminary step Mr. L'Estrange extracted the two incisors and a bicuspid which alone remained on that side of the jaw. I then plunged a trochar into the tumour above and parallel to the palate, with the two-fold object of ascertaining the density of the bone and of making room for a strong metacarpal saw. The bone was dense enough, but not so dense as to make it hopeless to work the saw. By slow degrees a layer of bone was separated from the floor of the tumour, partly by sawing and partly by the elevator—once it was necessary to use a chisel and mallet to free the saw. I tried two or three saws, but discarded all for the simple straight metacarpal saw. Having effectually separated this layer of bone from the floor of the mouth, I made a vertical incision from the inner angle of the eye to the ala nasi, skirting the attachment of the cartilage, and continued it down through the lip along the curved ridge which separates the outer portion of the lip from theiltrum or central part. I followed this line in preference to a straight cut, either vertically from the ala nasi or in the mesial line; and for this reason, that the subsequent contraction of the cicatrix in these lines leaves a more ugly pucker than when it follows the line of the natural ridge. By the help of Langenbeck's instruments the periosteum of the tumour was easily detached and turned aside along with the skin and muscles of the cheek. These being held strongly aside by my two chief assistants, I divided the malo-maxillary symphysis by a strong bone forceps. In the same manner the frontal process of the maxillary was divided, the periosteum peeling off with even greater ease, so that I was able to push it and the nose completely to one side. I now, with the bone forceps, divided the attachment of one maxillary bone to the other as near the mesial line as possible. Thus the tumour was detached on three sides. There remained the difficult task of sawing through the connexions of the tumour with the floor of the orbit. The bone was here dense as ivory, and the labour of sawing through it was severe and prolonged. At length, however, after breaking one saw this was completed, and the posterior attachments of the tumour alone remained; powerful traction by the lion-forceps caused these to yield, and a large mass was removed. Above and behind it some of the less dense portions of the tumour still lay; these were scooped out with the gouge, until all was removed which showed the least deviation from soundness. The large piece weighed over four ounces; and as I removed upwards of an ounce of smaller fragments, the weight of all fell little short of six ounces. This will give some idea of its size. A couple of small vessels required ligature; and three which bled freely from the surface of the bone, and which could not be ligatured, were stopped by platina wire, heated to a white heat by a galvanic current. The battery for this purpose was kindly brought by Dr. Bennett. I found it both simple and effectual. All active hæmorrhage being thus checked, I plugged the cavity with some half dozen

small pledgets of lint, tightly rolled and fastened to cords which were allowed to hang out of one corner of the wound. The soft parts in the mouth were first brought together by numerous points of interrupted suture, horse hair being used for the purpose. In a like manner the wound in the lip and cheek were closed. Two points were left for the escape of pus, and the withdrawal of the plugs and ligatures; one point corresponded to the former situation of the incisor teeth, and the other to the groove beside the ala nasi. With these exceptions the entire track of the wound was brought accurately in contact; no external dressings were applied. The patient bore the operation remarkably well; his pulse was 70 at its close, and very good in quality; he woke up quickly from the chloroform, and had no sickness of stomach. On being removed to bed he was ordered thirty drops of Battley's sedative, and as much ice as he might wish for.

3 P.M.—He had slept well since 12; pulse 72, and full. There is a little sanious oozing only. He is suffering a good deal of pain, but feels inclined to sleep again. He expresses a wish for some beef-tea, which was ordered; also to have tea whenever he wished, and ice. Iced water applied to the face.

8 P.M.—Pulse 92, full and strong—no further sanious oozing, but some discharge of saliva; he has slight nausea, attributed by himself, and rightly, to his having swallowed some blood during the operation. Ice, which relieves this sickness, to be continued. He passed water freely. The upper lip is swelling fast, and there is a good deal of pain about the orbit. To have ice or whey through the night.

10:30 P.M.—Pulse 90—sleeping calmly.

Feb. 8th, 1:30 A.M.—Has slept quietly for periods of ten minutes—the lip a good deal swelled—he continued to sleep off, and on, until 4 A.M., when his stomach rejected the whey; his feet became cold, and he had a slight rigor for about five minutes. Mr. Sibthorpe, who sat up with him, put a hot jar to his feet, gave him ice, and a draught, with twenty-five drops of chlorodine, and two grains of quinine, in camphor mixture; this had the desired effect; he slept quietly until 8 A.M., and had no return of sickness or rigor.

At 9 A.M. his pulse was 100, full and strong; at 10:30 I found his face a good deal swelled, especially about the lower part of the cheek. The eyelids were much ecchymosed, but could still be opened voluntarily. He made no complaint of pain, only of discomfort from the swelling, and from lying on his back. I allowed him to turn on his right side. As the bowels had not been moved, I ordered three grains of calomel, with one of quinine, and one of extract of hyoscyamus; these were taken at once, and operated in the course of the day freely, but not excessively.

At 2 P.M. his pulse was 96, and less full. He had beef-tea through the day.

5 P.M.—Stomach again slightly sick—ordered a gargle of permanganate of potash to clean the mouth. Ice as before.

His pulse went up to 100 in the evening, and remained at that rate through the night. He slept well, waking but seldom, and in the morning of the 9th his pulse was again at 96, but much less full and strong. The bowels were again moved.

At 10:30 I removed, one after another, all the plugs and the two ligatures, pulling them through the aperture left in the mouth for the purpose. There was no consecutive hemorrhage, and very little fetor; the discharge which accompanied the plugs was moderate in quantity. I syringed the cavity with tepid water, to which I had added spirit of ammonia in the proportion of a drachm to the pint. He had no headache, and was inclined to eat. Ordered—beef-tea, some light claret, and a mixture containing chlorate of potash.

3 P.M.—Pulse ran up to 120; wine stopped.

7 P.M.—Pulse down again to 96—no further signs of feverishness; has slept.

Feb. 10.—Very moderate discharge of pus from the cavity through the mouth. The discharge from the nasal

cavity, which, it will be remembered, was not opened in the operation, is simply viscid mucus. The swelling is already diminishing. Pulse 90.

Feb. 12.—Sitting up in the bed for some hours—able to eat a mutton-chop cut small—going on most satisfactory. The sutures in the lip removed. This portion had healed with little mark.

Feb. 15.—Daily improving; swelling much abated; appetite and sleep good; pulse 76. The greater number of the sutures were removed from the external part of the wound. All has healed by first intention, except a spot at the ala nasi, which is purposely left open for the convenience of syringing out the cavity; this is done once a-day; the discharge is not profuse; allowed to sit up for half an hour to-day (ninth day). Already some power is returning in the muscles of the cheek; the levator anguli oris is especially under the control of the will.

From this date to the 25th, when he left the hospital, he continued steadily to improve. In fact, he could scarcely be said to have had a serious symptom from the first. The slight rigor in the course of the first twenty-four hours was evidently due to his having swallowed some blood. This, slight as it was, formed the only check in the even progress of the case, while he remained in hospital. Subsequently to his return home he suffered from a small anthrax on the back of the neck; this, however, yielded to the mild, yet effectual treatment by pressure, which I have now for six years uniformly adopted, and with unvarying success, in every phase and variety of anthrax. I may here state incidentally that since I adopted treatment by pressure, or support, I have never met with an anthrax in which the disease continued to spread after the strapping was once properly applied; and I believe I have met with them in almost every possible stage and locality. In some rare cases of utterly broken down diabetics it may possibly fail to stop the gangrenous inflammation of the fascia, areolar tissue, and skin; but I presume that in such cases the knife would be equally ineffectual as a remedy. Even in such cases the combined action of the opium and of pressure would probably check, if it could not entirely control, the destruction of tissue. Plates III. and IV. show the appearance of this gentleman about the middle of March, six weeks after the operation was performed. Since then he has still further improved. The œdema of the nose and lower part of the cheek has subsided still further, and the cicatrix is less remarkable. The cavity is now closed, and there is no discharge from it. Power is returning to the muscles of the face.

As regards the structure of the tumour, it had probably been an enchondroma at first, but as years advanced it ossified, beginning from the centre. It was composed of consecutive layers, and the outer layers were probably the most recent, as they contained some fragments of imperfect or degenerate cartilage. The outside layer of all was made up of a bony case, derived from the proper tissue of the spongy bones and walls of the antrum. Under the microscope the bony plates differed little from ordinary bone; they were a little less regular as regards the arrangement of the blood-vessels.

As regards prognosis, this may be said, that the tumour grew slowly, and had a tendency to become inert in its older parts by a process of ossification. Like the Autumn leaf, its vessels and cells became gradually filled or narrowed by increasing deposits of earthy material, and less and less capable of active growth. We may, therefore, fairly hope that as we have removed all the active parts of the growth there will be no reproduction of the disease from the hard, bony floor of the orbit. Already the margin where the saw was used has fined down and rounded away. The huge cavity has been filled with soft granulations, which at first caused the cheek to bulge forward a little; with the natural contraction and consolidation of these soft granulations the cheek has gradually fallen into its proper level, and neither by touch nor in any other way can I detect any essential difference between the two cheeks. I have, therefore, good reason to hope that this tumour, which took thirty-five years to grow, may never be reproduced.

The patient may reasonably look forward to a long life, free from the distress and deformity which this enormous growth formerly gave rise to.

I cannot conclude this rather lengthened detail without a word of thanks to the many friends, professional and others, who evinced an unusual interest in the progress of this case. Next to those who personally assisted in the operation, my especial thanks are due to the resident pupils of the hospital, Messrs. Russell and Tredennick, and to my apprentices, Messrs. Scott and Sibthorpe, all of whom watched the case, and noted the particulars for me almost from hour to hour. Nor can I omit to add that the quiet determination and great patience of the gentleman himself tended very much to his freedom from dangerous symptoms, and to his rapid recovery.

#### AN ACCOUNT OF A REMARKABLE CASE IN WHICH DARK CUTANEOUS DISCOLOURATION OCCURRED SHORTLY AFTER DEATH:

WITH OBSERVATIONS ON ITS SUPPOSED CONNECTION WITH THE MORBID PHENOMENA RECENTLY KNOWN IN DUBLIN AS "BLACK DEATH."

By T. W. BELCHER, M.D. Dub., Etc.

FELLOW OF THE COLLEGE OF PHYSICIANS, AND PHYSICIAN TO THE DUBLIN DISPENSARY FOR DISEASES OF THE SKIN.

On Tuesday, the 19th of March, 1867, I was called in to see a young lady, aged 20 years, and unmarried. She resided in one of the best suburban streets of Dublin, was endowed with considerable personal attractions and accomplishments, had been more or less "of a nervous habit," as the phrase is; but, as to her general health, while never very strong, yet she had always been free from serious disease, and rarely troubled the doctor. On the preceding Saturday, one of the severe snowy days which the Siberian spring of 1867 brought us, she had gone to a friend's house, and while there had fainted. This was traceable to the fact that the catamenia, which with her were habitually regular, had been delayed a day or two beyond the proper time. At, or immediately after, this fainting fit, they came on, and presented nothing worthy of remark, but she felt weakened and knocked-up by the fainting, and so was in bed when I first saw her, three days after this had happened. I did not find anything serious the matter at this visit, and, beyond enjoining rest in bed, keeping the feet warm, using effervescing drinks of lemon-juice and alkali, and some purgative medicine to relieve constipation, with which then, as at other times, she was troubled, I adopted no active measures, as they were not needed. I need not continue a daily detail of symptoms, but it may suffice to say that very soon she showed most of the symptoms of acute, or, more correctly, *sub-acute* gastritis. Nothing remained on her stomach, and it was very difficult to hit on something which could be retained. The matter vomited was for a while biliary, and then green; there was no pain complained of over the stomach, but she frequently complained of a headache, which seemed to be more or less continuous and frontal. There was no intolerance whatever to light; the urine (though not tested) presented nothing abnormal; the pulse throughout her illness averaged from 76 to 84; the tongue was red at the edges, with intermitting patches of white in the centre; it was moist throughout, except for part of one day, when it was dry and brown; the skin was acting throughout the greatest part of her illness, and the only other symptom which appears worthy of note was the frequent complaints which she made of weary pains everywhere, but particularly in her limbs and back. After various trials of other articles of food, it was found that she could keep on her stomach Bass's bitterale and chicken jelly. On these articles she was fed for days, with claret occasionally, and now and then a little brandy and water. Ice was freely used, both by itself in the mouth, and in everything she took. As to medicine, she had an occasional purgative, at first by the mouth, and afterwards by enema. She also took for days together, with more or less intermission, two minims of dilute hydrocyanic acid,

with three grains of bicarbonate of soda in water every three hours, and oftener when necessary. She had laudanum soaked in a linen cloth applied to the stomach, and afterwards a poultice with four grains of opium in it applied in the same manner.

By steady perseverance in this mode of treatment she gradually got better and better every day. The vomiting became at first less in quantity, then less frequent, and finally disappeared. For parts of two or three days she had left her bed and lain on a sofa in the bedroom, and once she had gone down stairs in the evening. While the gastric symptoms were thus disappearing, she complained frequently of a cough. At first I thought this to be hysterical, but as it continued I examined the chest, and, finding some signs of irritation at the lower and back part of the right lung, I had turpentine stupes applied to it frequently, and so this symptom also abated, but not without disturbing the stomach a few times. Occasionally would come a fit of coughing, which sometimes resulted in forcing up the contents of the stomach. When this occurred, however (and I saw it myself), there was no morbid matter whatever discharged, but simply the food or drink which she had been taking a short time before. It differed thus from the gastric vomiting first noted, and was in fact put a total stop to by the application of a sinapism to the stomach. I may here add that she was nursed with the greatest care and good sense throughout her illness.

On Thursday the 28th March, was sent for to see her, in the afternoon, having visited her a few hours before, and found her friends in the greatest alarm about her condition. She had complained of what they conceived to be paralysis, a feeling of numbness creeping up the left side of the body to the top of the head, and including the limbs. As I could not be found when wanted for this emergency, Dr. Powell, of Upper Leeson-street, to whom an account of these symptoms was given by one of her sisters, sent her a mixture containing sal volatile and chloric æther, the administration of which completely disposed of the symptoms already detailed, so that when I arrived soon after, there was no appearance of them whatever. For some time from this date the patient manifested various symptoms which I looked on as hysterical. There was the occasional rejection of the contents of the stomach which was stopped as before mentioned, this vomiting largely depending on the power of volition; for I found that as a rule, such things as I myself gave the patient, requesting her at the same time to retain them, were for the most part retained; while the rejection of food generally took place in my absence. The mere fact of touching her limbs as she lay inclined to the left side, seemed to occasion her acute pain, unless reasoned with; so also with the power of swallowing, of opening the mouth, of moving the head, which latterly became drawn to the left side, and of other movements which were plainly under the control of volition. She had convulsive movements also; threw the arms about; felt the weight of the bed clothes, and pulled them partly down; kept grasping some imaginary objects with the hands, and occasionally putting the hand to the throat as indicative of a sense of suffocation. Then there was occasional delirium, out of which she was easily roused by me, even when she could not be roused by her own friends; there was constipation removed by enemata of tincture of assafetida, which also modified—or after which were also modified—several of the symptoms just mentioned. The urine at first passed naturally, then was suppressed, but came away copiously and involuntarily after stuping the pubic region with hot water.

The skin was of normal temperature, with occasional diaphoresis, and the general tranquility of the circulation was specially worthy of note. The headache was not at all complained of as at first, and complaints respecting it soon ceased; sleeplessness was more or less complained of; nourishment and suitable support were continuously given, and with invariably good effect on the cutaneous and circulatory systems. There was a total absence of convulsive movements of the muscles of the face; the pupils were not dilated; there was no morbid appearance on the skin,

which was then, as in health, remarkably fair. On Sunday evening the 31st of March, I found that she had passed a sleepless day, and that the delirium could not be interrupted as before, though after a few attempts I succeeded in making her recognise me and address me by name. I gave her a dram of tincture of hyoscyamus in some sherry, (for now she retained every thing on her stomach), and also a variety of nourishment, all of which she took from my hand without demur or difficulty. On the next morning (1st of April) having found that she had passed a sleepless night with more or less noisy delirium and resistance to her being in any way moved in the bed; I poured a considerable quantity of cold water over her head; and this had the effect of making her quiet almost at once, and any weakness or depression caused by it was soon remedied by external heat and internal stimulants, which acted on the circulation as soon as given; the general result being that the pulse fell from 120 to 84, in about fifteen minutes; and though now weak and again comparatively strong, it kept pretty steadily to this number throughout the day. I now observed her pupils to be somewhat dilated, but not remarkably so, and this was while she lay with her back to the light. In the course of the day I had the advantage of a consultation with Dr. Churchill, who saw the case with me. The hydrocyanic acid was desired to be continued, with the addition of a little of Batley's sedative drop, twenty-five drops of which were ordered to be given at night; also a blister to the neck, and suitable support and nourishment. At night I myself gave her the sleeping draught, which she took and retained, and which, the nurse informed me, soon sent her to sleep, but only for a short time. The blister also rose well. The circulation was kept up, and urine had been copiously passed through the day. The skin was also soft, but when I last saw her alive, she was not perspiring. I was knocked up at 4 A.M. on the 2nd of April, and on arriving at the house found that she had been dead about an hour. From Dr. Powell, of Upper Leeson-street, who had been sent for, I learned that soon after three A.M., he came and found her grasping at her throat, unconscious, and dying. As she had trismus which would not yield, he could not give any restorative by the mouth, but administered strong solution of ammonia to the nostrils, and put a sinapism to the throat. This plan caused a temporary, but momentary reaction; and so the patient ceased to breathe. A post-mortem examination was not obtainable, and as I was aware of the existence of cerebro-spinal arachnitis in Dublin at present, and as, in consultation with Dr. Churchill, the masked and complicated nature of the case had been mentioned in connection with the possible existence or supervention of that affection, I resolved to obtain such post-mortem information as I could get by viewing the remains. Accordingly, when I saw the body at 4.30 A.M., it was perfectly unmarked by any discolouration. About mid-day, I was not surprised to hear, in answer to my query, that it had soon after death turned black, or dark purple, to a large extent—the face, hands, legs, but not the feet, and all the back parts, from the neck downwards, being so affected. I went up and saw it, and perceived that this colour had disappeared from some of these places, particularly from the front of the face, but it yet remained on others. The hands were convulsively closed, and could not be straightened, the right foot was convulsively inverted, and the eyelids could be kept closed only with difficulty. The abdomen was enormously swollen, and black blood in quantities had been largely pouring from the mouth, and continued so to pour all day, so that the body had to be put into a coffin that evening. With this there was a most offensive smell of decomposing animal matter. Late that night, some time after the body had been laid in the coffin, a convulsive movement of the abdomen took place, somewhat resembling vomiting, and was followed by the ejection from the mouth of a quantity of black bloody matter, with a smell which no perfume, and not even chloride of lime, could cover or dispel. Next day the face had become covered with purpuric spots, and had so swollen, that it could not

be easily recognised, and so thorough and rapid was the decomposition, that the coffin had to be closed. I never before saw a case in which the human face became so quickly decomposed, and literally "dissolved;" and it was the more remarkable, as it was one of unusual comeliness, which, throughout an illness ranging over about eighteen days, had not exhibited even the ordinary changes which the countenance undergoes in disease. What was the immediate cause of death in this case? Probably cerebro-spinal arachnitis, or, more correctly, cerebro-spinal meningitis; for, to assert that the arachnoid membrane was chiefly or solely affected, would be to assume what could only be decided by the pathological evidence afforded by a post-mortem examination.

In the well-known paper which the late Dr. Mayne published on "Cerebro-spinal Arachnitis," in the *Dublin Quarterly Journal* for August, 1846, that eminent physician stated his opinion, that the disease which fell under his observation at that time, consisted "essentially in acute inflammation of the membranes which invest the brain and spinal marrow;" and he further observed that "the arachnoid seems to be its especial seat;" that "the spinal arachnoid always suffers much more severely than the cerebral;" and that "the substance of the brain and spinal marrow appeared remarkably free from lesion; there was no unusual vascularity or softening apparent, nor did the ventricles betray any evidence of inflammation." Dr. Mayne's description of the symptoms is so concise, and differs so materially from that observed in this case, that I have no hesitation in giving it entire. After stating their formidable nature, and the sudden and unexpected accession of the disease, he proceeds thus:—"In the majority of cases the patient has been in his ordinary health and spirits up to the very moment of the seizure, and has experienced no premonitory symptoms to warn him of his danger. . . . In many instances it commences with severe pain in the abdomen, followed immediately by vomiting, and not unfrequently by purging. In the worst cases these symptoms are accompanied by marked collapse, the extremities are cold and blueish, the pulse at this time is a mere thread, and altogether the disease assumes very much the aspect of cholera. After the lapse of a few hours, reaction, more or less perfect, ensues; the muscular system then presents characters which may be considered almost pathognomonic. The muscles of the extremities, and those of the neck in particular, become remarkably rigid; the head is drawn back upon the vertebral column, and firmly fixed in that unnatural position; no efforts of the patient can bend it forward, neither can the attendants do so, at least by the employment of any justifiable force. The countenance at this period often assumes very much the tetanic expression; twitchings of the muscles of the face sometimes ensue; the patient loses, in a great measure, the power of moving his extremities, so that he is quite unable to assume the erect position; the surface becomes hot; the pulse full and frequent (from 120 to 140); the stomach often continues irritable, whilst an insatiable thirst torments the sufferer; and the epigastrium evinces marked tenderness upon pressure. Symptoms of a still more distressing nature quickly supervene. The patient may be seized with general convulsions of frightful severity, requiring personal restraint to protect him from injury; or he may lie in a semi-comatose condition, constantly moaning and grinding his teeth, or even crying incessantly. Towards the close of his sufferings he generally merges into perfect coma, the pulse becomes slow and laboured, the powers of speech and deglutition fail, his stools are passed involuntary, and death finally closes the scene. All this may occur in a surprisingly short space of time; some of the cases ran their course in forty-eight hours, and the greater number terminated about the fourth day, whilst some few were prolonged over a fortnight or three weeks. Examples are on record of death from the disease in so short a period as fifteen hours." Dr. Mayne then further remarked, that while in some cases symptoms indicative of mischief within the cranium were observed—such as pain in the head, heat of scalp, congestion of the conjunctiva, strabismus, intolerance of light,

&c., yet, in many, no such evidence occurred. He also remarked (following Dr. McDowel) that in some cases the patients were sore all over, and winced on the least touch, refusing to change their posture in bed from the pain consequent on the slightest movement; "but far more frequently a diminution of tactile sensibility and confirmed stupor have afforded grounds for the worst anticipations." Irregular and laboured respiration, in the absence of thoracic disease, was also noticed by Dr. Mayne "as a leading symptom;" and in two cases in which he made a post-mortem examination he "found the abdominal viscera absolutely healthy," notwithstanding that decided gastric symptoms "persisted in a very marked manner to the close."

IN THE MEDICAL PRESS AND CIRCULAR for 16th May, 1866, were published details of a case of what was then called "Black Death," which had recently occurred in the practice of Dr. Lyons of this city. A reference to the report of that case will show that it had some remarkable features in common with, and some differing very widely from, those observed in this case. In Dr. Lyons's case, death took place in sixteen hours from the first attack, which was ushered in with chills, headache, and sick stomach, (the last two of these symptoms afterwards disappeared), with an intolerable sense of weariness and pain in the legs, back, and shoulders. There was no hæmorrhage from any part, but the prominent symptom—which remained after death—was the presence, on most parts of the body, of "irregularly shaped dark purplish patches . . . with a general dusky purplish discolouration of the intervening skin." No post-mortem examination could be had in this case. In the same Journal for 23rd May, 1866, another case, which post-mortem examination showed to be one of cerebro-spinal arachnitis, is reported in Dr. Lyons's Clinique. In this case, which lasted forty days, there were no gastric symptoms, or signs of nervous excitement or delirium, as in the case above given by me; in other respects it corresponded to the symptoms described by Dr. Mayne. In May last, I saw a remarkable case at Sir P. Dun's Hospital, under the care of Dr. Banks; and in it, also, pathological evidence after death proved it to be cerebro-spinal arachnitis. The duration of the disease, in this instance, was about three days, and when I saw the patient on the third day, he was discoloured with violet staining of the skin on various parts of the body, but without extravasation. In the account of this case given in THE MEDICAL PRESS AND CIRCULAR for 30th May, 1866, the symptoms and pathological appearances which coincided with Dr. Mayne's cases are given with Dr. Banks's remark, that "the deep discolouration of the skin was also a strange and peculiar feature." Unconsciousness occurred at the outset in this case. In the same journal for 13th June, 1866, (MEDICAL PRESS AND CIRCULAR), Dr. Little, F.R.C.S.I., relates a case of "Black Death." "The advent of the disease [he writes] was marked by a dusky discolouration, its progress by deeper-tinting, and by the development on the face, hands and feet, of broad dark patches, which, as the disease advanced, became more intense in colour, and at its termination resembled the bruises of a hammer. . . . From first to last, [the disease lasted four days], restlessness, anxiety, and semidelirium, excitement of the circulatory and respiratory organs, and spasm of the voluntary muscles, were present." A recent case of "Black Death" was published by Dr. Ridley, F.R.C.S.I., in the PRESS AND CIRCULAR for 3rd April, 1867.

This case, during which the patient was conscious up to an hour before death, lasted twenty-nine and a-half hours, and closely resembled those of Dr. Lyons (at least, the first and last mentioned of them), not only in the general symptoms, but also in the peculiar spotted discolouration of the skin.

From all this I conclude, that if a post-mortem examination had been made in the case which I have detailed, there would have been found evidences of meningeal disease, at least as far as regards the spinal column.

Analogy would lead us to expect this, while the great dissimilarity of this case in some respects to any or all of

the others mentioned or described, should not be held to militate against this view; for of those cases, in most of which there was a terrible but indescribable affinity, some were sudden, others were lingering; some had head symptoms, others had not; some had diarrhoea, others had not; and so on with nearly all the symptoms except those which occur commonly in other diseases; and one or more of these other diseases might precede or be complicated with cerebro-spinal symptoms—*e.g.*, headache, pains in the bones and back, sickness of stomach, &c., occur in other affections, one or more of which might precede or be complicated with cerebro-spinal arachnitis.

Perhaps one of the best and most recent treatises on cerebro-spinal meningitis (in English) is to be found in "Flint's Practice of Medicine" (pp. 534, &c.), published in Philadelphia in 1866. A careful reading of this treatise further convinces me of the great variety, the masked, and even opposed, nature of the symptoms of this affection in various cases; and I could not clearly identify the case above described with Dr. Flint's description, any more than with any of those already quoted, or with those of Dr. Darby, of Bray, who, we must not forget, gave us such early and important information on this subject, in THE MEDICAL PRESS of April 1st, 1846.

With regard to the symptoms which I have called hysterical, I may note that the mother of this young lady died, about six months before, from a comparatively rare form of uterine disease, during the last stage of which she had convulsions and nervous symptoms, strongly resembling those in the present case. She also had uræmic poisoning which did not exist in this instance. Moreover, the young lady was a marked example of what Dr. Todd, in his clinical lecture on local hysteria and catalepsy, (Beale's edition, p. 885), has called the "facies hysterica," and his remarks on the symptoms of hysteria and its general but not universal connection with uterine irregularity, however slight, are very much to the point as regards this case. What hysteria really is, is a much more difficult question to answer than the converse, what it is not. I take it to be, as defined by a writer whom I have already quoted, and whose chapter on this subject bears strongly on the present case (I mean Flint, pp. 619), "an abnormal condition of the nervous system and the mind which enters largely, as a morbid element, into a great variety of affections." The same writer further remarks, that "as regards prognosis, hysterical attacks are proverbially devoid of danger. The practitioner, however, is not to lose sight of the fact, that hysteria may be associated with affections which are serious."

I have already spoken of the gastric symptoms which manifested themselves almost at the outset of this case. Except that the patient did not complain of pain in the region of the stomach, I think the description which the late Dr. Cathcart Lees published of what he called "Subacute Gastritis," (Lectures on Diseases of the Stomach, &c., Dublin, 1857, pp. 21, &c.) answers fairly to most of those exemplified in this instance. They were such as might have been looked for, or at least not considered unusual, from the nervous shock arising out of uterine irregularity as already noticed. The post-mortem appearances were certainly unusual, and I do not pretend to offer any explanation of them. In some respects they resembled, though in an exaggerated degree, Frerichs's description of the disease described by him under the name of "Acute Atrophy of the Liver," (Clinical Treatise on Diseases of the Liver, vol. i. pp. 196, &c.) but the case here recorded wanted two essential symptoms which Frerichs observed in his cases: jaundice and discolouration of the skin, with hæmorrhage, *during life*. I do not know if the beginning of this case may not be fairly referred to what Dr. Churchill and other writers on "Diseases of Women" describe under the name of "Reflex Irritation from Disorder of Menstruation." (Churchill, pp. 239, etc., 6th edition, 1864). At any rate it seems abundantly clear, so far as symptoms can justify any one in making a diagnosis, that the lesion was in the nervous system throughout.

In writing of the rapid, almost immediate, decom-

position which set in when life became extinct, I used the term "dissolved" with reference to the body; and I did so advisedly. A sacred writer describing the death of the body under the figure of the dissolution or taking down of a tabernacle or tent, used the word *καταλυθῆναι*, usually translated "were dissolved" (St. Paul, 2 Cor. v., i.), and which, in another form, is elsewhere used in the architectural sense of "taken down" (*καταλυθήσεται*), with reference to the complete pulling down, or utter destruction of the stones of the temple at Jerusalem (St. Mat. xxiv., 2). Now this word in another form, *κατάλυσις*, is the technical *catalysis* with which we are all more or less familiar, and which could, with much propriety, be used in reference to the case here attempted to be described and recorded.

Since the preceding remarks were written, I have read the account of the case of so called "Black death" published in THE MEDICAL PRESS AND CIRCULAR of April 24, by Dr. Benson, junr., of this city. It goes far to show that there is no necessary connection between the cutaneous discolouration and cerebro-spinal arachnitis. I do not consider the phrase "black death" at all a proper one as applied to the cases lately called by that name. Any one who has read the vivid description of the mediæval black death, to be found in Hecker's "Epidemics of the Middle Ages," will admit the force of this assertion; and I need only refer the reader to chapter 2 of his work, where, after stating that the most memorable example of that great pestilence was the plague which desolated Asia, Europe, and Africa in the fourteenth century, he states that "It was an Oriental plague, marked by inflammatory boils and tumours of the glands, such as break out in no other febrile disease. On account of these inflammatory boils, and from the black spots indicative of a putrid decomposition, which appeared upon the skin, it was called in Germany and in the northern Kingdoms of Europe the black death, and in Italy, la mortalega grande—the great mortality." (Hecker chap. ii., p. 2, Sydenham Society's Edition.)

## Hospital Reports.

### METROPOLITAN FREE HOSPITAL.

CASE OF TINEA TONSURANS IN A CHILD AGED NINE YEARS, ACCOMPANIED BY CHOREA, WITH OBSERVATIONS.

Under the care of Dr. CHARLES DRYSDALE.

MINNIE W., aged 9, a delicate little girl, was seen by Dr. Drysdale on 18th February, 1867, affected with chorea and falling of the hair in a circumscribed spot. There is on the occiput a small circular space of the diameter of a five-shilling piece, from which the hair has fallen. The colour of the skin is slightly reddish, and has a few white scales on it; it sometimes feels itchy; round the circumference of the bald patch the hairs are dull and broken off at about one-eighth of an inch from the scalp; there are neither vesicles nor pustules present. The patient is subject to chorea Sancti Viti, and this makes her almost unmanageable at night. A hair from the patch being examined under the microscope, shows that the root is not bulbous, but nearly destroyed, and the hair near the scalp has swellings on it, in the midst of which are seen the spores of a cryptogamic plant. The end of the hairs broken off near the scalp exhibits the appearance of a brush, being split up by the multitude of spores of trichophyton tonsurans. Dr. Drysdale ordered the hairs in the circumference of the patch to be pulled out with tweezers, and a sponge dipped in the following lotion—hydrargyri bichloridi, gr. xv.; aquæ oj. —to be applied to the part, as a parasiticide, night and morning.

April 2nd.—The disease has been checked, and there is no longer any necessity for treatment.

Tinea tonsurans is one of these affections which have been grouped together by Hardy, under the name Trichophyte. The other two being herpes circinatus and sycosis. The same or a similar parasite appears to cause all these diseases.

The name herpes is ill chosen in the cases of these parasitic diseases, since neither in herpes tonsurans nor herpes circinatus are vesicles frequently observed. These three diseases were always considered to be quite independent of each other, until M. Bazin and M. Hardy, of the H. St. Louis, Paris, discovered that they were identical. This opinion, however, is not admitted universally—some asserting that they have never been able to find a specimen of the fungus in the case of mentagra; but neither is it easy, in many cases, to find an acarus in many old cases of itch, where numerous eruptions have disfigured the body. The disease h. circinatus is easily recognised. It is characterised by one or more isolated, red, slightly-raised patches, surmounted by little, dirty white scales, which, as they extend in surface, get well in the centre. There is generally a feeling of itching; but no general symptoms are present. It is generally seen in the face—sometimes in other situations.

Tinea tonsurans is found on the scalp in rounded patches, on which the hairs are dull, dry, and broken off at about one-eighth of an inch from their base. The diseased part is swollen, and the epidermis raised in form of scales. The parts are generally itchy. Sometimes there are vesicles, sometimes pustules, though these are often absent. If we pull out a hair from a plate of tinea tonsurans, and place it beneath the microscope, we are struck with the alteration of its root; in fact, in place of having that rounded aspect which it generally presents, and which makes it resemble a bulbous plant, it is flattened, cut short off, and sometimes destroyed. The hair is bent, and has knots on parts of it, or swellings, at which points it seems burst and split up, and nothing but a heap of spores is to be seen in it. At the end of the broken hairs the hair looks as if it were a brush, its longitudinal fibres being separated by spores. These spores are in immense quantities in h. tonsurans, and but little mycelium is to be seen in this fungus. In some cases this disease is spontaneously cured; but generally it goes on to produce incurable baldness by the destruction of the hair follicle. This result sometimes requires a long time, as much as ten or fifteen years in some cases. The diagnosis of tinea tonsurans from impetigo and from syphilitic eruptions is to be made by a microscopic examination. It is not so necessary to diagnosticate tinea tonsurans from favus, because the treatment is identical in both of these cases. Tinea tonsurans is scarcely seen except in children: whilst h. circinatus appears at all ages. The sole cause of these diseases is contagion, and hence it rages in schools. The scientific treatment of the disease consists in pulling out the hairs, and then using a parasiticide lotion night and morning, in order to destroy the fungus in the hair follicles. The lotion most recommended is as follows: hydrarg. bichlor. gr. xv.; alcohol, q.s.; aquæ oj. ft. lotio. A sponge or hair pencil is dipped in this, and the orifices of the follicles frequently wet with it. It is sometimes difficult to pull out the hairs, but it must be done as well as possible.

### RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

Dr. LYONS'S CLINIQUE.

#### PERICARDITIS AFTER TYPHUS.

TOWARDS the close of the month of March, a case of interest terminated at the Hardwicke Hospital, under the care of Dr. Lyons. The patient was a lad, aged seventeen years; and he had been some weeks in hospital at the time of his death. He exhibited all the characteristic symptoms of typhus of a low type, with depressed circulation and enfeebled heart. Soon after his admission, Dr. Lyons observed the development of a very extensive diphtheritic exudation on the throat, which threatened at one time to be a fatal complication. It was not so, however; under prudent and watchful management this symptom was overcome, but only after much trouble. For seven days or more the exudation was now appearing, and again re-appearing on the throat, and this notwithstanding the various local and general modes of treatment used for it. Near

the end of the fourth week the patient was making a fair recovery, and most of the grave symptoms had disappeared, when Dr. Lyons observed a peculiar irritability of the pulse, which rose to 120; and also a distinct increase of the cardiac action. Dr. Lyons did not readily incline to the opinion that anything of an inflammatory nature was likely to attack the heart at this advanced stage of typhus, but a few leeches were applied over the region of the heart with the result of producing some relief to the patient. In a few days the symptoms became gradually more aggravated, and the lad died on the 27th day of his illness. The symptoms had taken a sudden turn for the worse; and in order to explain and account for this, Dr. Lyons had a post-mortem examination made some hours after death.

This examination was made with great care by Mr. Crauford, Dr. Lyons's clinical clerk, and with the result of affording evidence of acute pericarditis in an advanced degree. The entire pericardium and the surface of the heart were covered with lymph. There was effusion of fluid to the amount of eight or nine ounces into the pericardium; and, therefore, Dr. Lyons concluded that the sudden occurrence of this effusion was the cause of, and sufficiently accounted for, the rapidly fatal issue of the case.

Hereon Dr. Lyons remarked that, in his experience, this was the second case of pericarditis proving the immediate cause of a fatal termination in typhus, and, on looking over the standard works on the subject, he found that it was a very unusual complication. In the first case which Dr. Lyons saw, the patient died on the twenty-fifth day of his illness with characteristic symptoms, and although he could not give proof similar to that in the present case, viz., by the result of a post-mortem examination; that the proximate cause of death was pericarditis, yet no doubt existed in his mind that such was the case. The friction sound was exceedingly well marked, and it was noticed that this person had shown extreme debility in the circulation; extremely feeble impulse, and extreme debility of the cardiac sounds during the second week of his illness. The same symptoms existed in the case above noted, and Dr. Lyons considered it remarkable where the heart was so debilitated that in a disease like typhus, which, as the researches of numerous and well qualified observers showed, produced so remarkable an effect in weakening the cardiac muscles; that at the termination of such a case the heart and its investing membrane should be enabled to "take on" inflammatory action of so high a degree as this. Dr. Lyons was also of opinion that, looked at from another point of view, this case was interesting; the exudation of lymph on the pericardium might be connected with the exudation of lymph in the throat, as a characteristic feature in this particular case.

Dr. Lyons exhibited the morbid specimens obtained at the post-mortem examination in this case at a recent meeting of the Dublin Pathological Society.

#### CURRENT LITERATURE.

THE *Eight Annual Report of the Sussex County Lunatic Asylum*, at Hayward's Heath, is, on the whole, a satisfactory one. The rate of mortality during the year has been rather higher than usual, but this is explained by twenty-five cases having been admitted in a hopeless, some of them in a dying, state. In connection with this Asylum, two small houses, to serve as cottage hospitals for the two sexes, have been purchased last year, with the intention of removing to them any cases of infectious disease that may arise. We should also notice that Dr. Robertson, the Medical Superintendent, has adopted the form of tables for his statistics, recommended by the Medico-Psychological Association, which have been approved as suitable for general adoption by the Commissioners in Lunacy.

The *Second Annual Report of the Burntwood Asylum* (Staffordshire), shows rather a less mortality than had been expected. The Asylum accommodates 214 inmates, of

whom 155 are of the male sex. The construction is scarcely yet completed, as the papering and painting, &c., of some portions is still proceeding. The average cost of the patients per annum has been at the rate of 9s. 11d. a-week each. The average weekly number of inmates has been 206. The Medical Superintendent, Dr. R. A. Davis, speaks in high terms of the manner in which the nurses and attendants have discharged their duties, and expresses his thanks for the hearty support he has had from the Committee, in organising this new and promising Asylum.

The *Popular Science Review* opens the current number with an article on "Insect Embryogeny," by Dr. Fripp, of the Bristol Medical School. Then follows a very interesting account of the "Struggle for Existence amongst Plants," by Dr. Hooker. Mr. Chambers gives some practical observations on "How to Study Meteorology," showing how simple and easy it is for any one so inclined to amass valuable facts. Mr. Barrett's article on "Sensitive Flames," is a fair sketch of the subject. Dr. Atfield treats of "Paraffin Lamps and their Dangers;" and Mr. Bates winds up this part of the review with an "Attempt to Approximate the Date of the Flint Flakes of Devon and Cornwall." The scientific summary is copious and varied, and forms a feature of this journal. The reviews proper, are not numerous, nor particularly carefully done. In this department alone do we see need for improvement.

The *Journal of Mental Science* for this month contains, as usual, in addition to original communications and reviews, a valuable Quarterly Report on the Progress of Psychological Medicine, and a brief epitome of English Psychological Literature. In the notes and news department, the correspondence of the Commissioners of Lunacy respecting the London Surgical Home necessarily takes the first place. We turned to it with interest, expecting to see this point treated with the impartiality of such able men outside recent debates, as the editors of this journal, and were surprised to find the only comments to consist in two stale quotations from the *British Medical Journal*, which are quite destitute of argument, and only advance a statement that the *British* has the "best authority for stating" that the Commissioners are considering the subject.

WATTS' DICTIONARY OF CHEMISTRY. London: Longman, Green. Reader, Dyer. Parts 35 to 38.

PARTS 35 to 38 takes us from "Quadrantoxide" to "Stilbite." The principal articles occurring in the numbers are on Quinine and its Salts; Radiation and Conduction of Heat by Professor E. Foster; Respiration by Dr. W. Foster; Secondary Alcohols by Professor Wanklyn; Silicates; Soap; Sodium, and its Compounds; Specific Gravities; Spectrum Analysis, and Starch.

The last but one is from the pen of Professor Roscoe, and is carefully illustrated.

As it is our intention to review this important work on its completion, and in its integrity, we now only notice its progress, but wish at the same time to offer a suggestion. The dictionary will take about four or five years in issuing from the press, and it will be many years before a new edition of such a book can be re-issued. In fact, the value of such works, which are for the purpose of reference, is generally gone long before a new edition is contemplated.

Mr. Watts should therefore issue a yearly appendix, which, we have no doubt, will be as valuable to possessors of the dictionary as it will be remunerative to the publishers. The editor has succeeded in giving us a book, which, from its great merits, has made his name familiar to all men of science. He is therefore under an obligation to keep it written up to the requirements of the day. This cannot be done by the desultory publication of fresh editions after long periods of rest.

WEDNESDAY, MAY 1, 1867.

### THE SUMMER SESSION.

THE day on which this number of the MEDICAL PRESS AND CIRCULAR comes into the hands of the reader, the Medical Schools open the Summer Session. As the students return from their brief holiday to the duties of preparing themselves for their futures, a few words of welcome and advice may not be out of place. Those who have energetically pursued their labours during the past winter, will have laid for the coming summer's work a broad foundation on which they can now commence to build. Even a first-year's man who has plodded along in the beaten track, can scarcely have failed to have acquired so much anatomical knowledge as to facilitate his progress in some of the more practical subjects that will now be laid open to him. If he has only frequented the dissecting-room to an average extent, with his observant faculties in full exercise, he must have obtained a store of important knowledge with which to supplement the regular course on Anatomy, and the reading to which that naturally leads. He may, therefore, come back to work, refreshed by the month in the country, and thereby prepared with renewed energy to grasp the subjects of the briefer term, and make their details his own for future use. He may do this with ordinary diligence, feeling, as the weeks pass by, each one brings him nearer to the desired goal.

On the other hand, the idler who has wasted the winter, alas! that there should be any such! while he may have needed the month's recess to recruit his health, he can scarcely have given himself up to the thorough enjoyment of his holiday. Thoughts of wasted time must have marred many of his pleasures, and the fear of examining Boards before his eyes, must even now lend point to the exhortations of his teachers to strive to retrieve himself. Unless he would abandon all hope of accomplishing the task before him, he must strain every nerve to make up for lost time. By dint of labo-

rious days and studious nights, if blest by natural ability and strong health, he may yet hope to win back, as it were, from time, some of the advantages he has so carelessly let slip. Let him then at once make one firm resolve and enter on the struggle with all the energy of youth, and the deep conviction that success depends on a supreme effort. It is a hard task, indeed, to cram the work of a year into three months, but in this case it must be done; and at every institution, we rejoice to say, there are amongst the teachers some who will gladly aid every misguided pupil who is ready to turn his back upon the blandishments of ease, and live laborious days. We add our voice of welcome to all—the most diligent, who are sure of success, on the one hand—the most idle, who fear the worst, on the other. To the former we say go on and prosper. To the latter we whisper the word of encouragement *nil desperandum*. To both we say, keep steadfastly before you for the future the great end of your studies—not the mere possession of licenses to practice, but the ability to follow your profession with credit to yourselves and benefit to your patients. With this aim constantly in view, great as may seem the effort required, and extensive as truly is the information to be stored up, you may work and hope, finding that day by day, week by week, and season by season some progress is made, and in the end you will prove the great truth, *Labor omnia vincit*.

A word respecting the classes which the student has now to attend. First of all is the important subject of midwifery, one of the first necessities in actual practice is a familiarity with this branch of the healing art. Wherever the future lot of the student may be cast, he may at any moment be summoned to display the skill he has acquired. In no department will he have greater opportunities of exercising all those qualities which make the able practitioner. In none may he have more need of that self-reliance which is inspired by knowledge, and that ready tact called out by unexpected difficulties, which even the patient and those around, though they may not understand, will appreciate and reward with confidence. It is true that in a large majority of cases the exercise of patience, and the exhibition of that simple and kindly sympathy and delicacy that constitute the conduct of a true gentleman may suffice. But on other occasions, the need for other and perhaps sterner qualities may be urgent. With no assistance near, the life of a fellow-creature, the happiness of families, may depend on the prompt exercise of the highest professional skill and courage.

If we add to midwifery the allied subject of diseases of women and children, we have at once, as a study, at least two-thirds of the actual practical part of the Profession—surely a sufficient reason to incite the student to earnest work, and enforce upon him

the absolute necessity of mastering the Summer Courses. Beside this, the other lectures seem to grow less important; but they, too, must not be neglected.

Perhaps the next in order of importance is *Materia Medica*, for it is a branch of knowledge that in practice is called into daily requisition, and many of its details must become "familiar as household words." It has not, however, the same element of requiring the practitioner to be ready for sudden peril, that renders Midwifery of such paramount interest, while the almost necessary acquaintance with its outlines for the simplest purposes renders it less liable to be neglected.

Botany may, perhaps, be regarded, so far as it is necessary to urge it upon attention, as an agreeable branch of *Materia Medica*. In the botanical excursions now so regularly organised, the student will find recreation and healthful amusement, which may relieve his harder toil.

Practical Chemistry and Forensic Medicine are two departments that are sometimes thought too little of. Both have been followed in this country as exclusive professional occupations; yet it may happen that any practitioner may be called upon for his opinion. Besides which, including what has been called Toxicology, these sciences may at any time be needed in ordinary practice. It may not be essential to be able to analyze the medicines employed, or the products of disease, or to offer opinions in aid of justice; but it may at any moment be a question of life or death to be able to diagnose a case of poisoning, and to administer the proper antidote.

In offering these observations on the chief topics which will occupy students in the Session that opens to-day, we have no wish but, from an independent position, to confirm the wise counsels which, we doubt not, will be offered by the Professors, and encourage, with a word of sympathy and an assurance of our interest in their welfare, those who are preparing themselves for the practice of our Profession.

What we have said will, we trust, be received in as kindly a spirit as it is intended. Written with a vivid recollection of our own experience in student days, it contains the sum of our experience on the subject since. To complete our advice, we have but one thing to add: while diligently acquiring new knowledge, to prevent, by a use of that already gained, the labour of the past being partly lost, through the memory loosening its hold on subjects in which it is not sometimes exercised.

### Notes on Current Topics.

**THE ROYAL FAMILY.**—Since we last alluded to the subject, the progress of the Princess of Wales towards recovery has been steady though, unhappily, slow. It is a source of regret on all sides that the prospect before Her Royal Highness is still of necessity for rest.

THE Princess Christian has recovered rapidly and without a bad symptom from her confinement, and already there is a talk of her visiting Windsor.

**THE EASTER VOLUNTEER REVIEW.**—It is satisfactory to be able to report that the Volunteer Review at Dover, on Easter Monday, passed off without any serious casualties. Every preparation was made to meet any accident that might occur, and the arrangements for that purpose have been pronounced on all hands faultless. We have not the slightest doubt that the Surgeons of the Volunteers will always be able to discharge such duties as may fall to their lot, and while congratulating them on the absence of sad accidents at the Easter display, add our word of commendation for their efficient preparations for the occasion.

**THE METROPOLITAN POOR ACT.**—This important measure has received the Royal assent, and is now therefore law. We shall take an early opportunity of submitting it to our readers, probably next week. Its provisions, in many respects, have already been discussed in our columns. There are, however, not a few points to which we shall have occasion to direct attention.

KARL ANDERSON has been respited during Her Majesty's pleasure. In this case the decision of Mr. Walpole will be supported by the opinion of the whole community. We should be very glad, however, to hear that his life is not spared merely on account of Mr. Walpole's opinion, but that some such investigation, as we last week suggested, into his mental condition will be undertaken, and the Profession made acquainted with the evidence elicited.

**DOMICILIARY SANITARY INSPECTION.**—Under this heading a correspondent of the *John Bull* newspaper proposes the appointment of female sanitary inspectors to visit houses and examine those parts of the premises most likely to escape the eye of the mistress. The writer is well aware of the objection that would be felt by many to allowing their houses to be thus inspected, but maintains that as the plan would only be voluntary, there would really be no intrusion into the sanctity of the household, nor any invasion of the "Englishman's castle." It is scarcely to be denied that a large number of persons are well qualified for the task proposed, and that such occasional inspection would probably prove more efficient than the constant eye of the untrained lady of the house, who is in reality, to a large extent, almost excluded from some corners of her own establishment. Again, if we could learn from what fund these inspectors could be paid, benefit would be conferred on many deserving persons. It is stated that many applications for the post have already been received. Should the idea be practically carried out, we trust only those of superior education would be employed. To commit such an inspection to ex-housekeepers and cooks would decidedly destroy all chance of its success. A thorough lady would be able, by her own natural instinct, so to act as to secure the good-will of both mistress and servants. It is the ignorance, obstinacy, and neglect of domestic servants that make half the non-sanitary conditions of our houses. It is in the basement that we must seek most of the causes of disease which would be removed by the proposed plan. Moreover, one object of the inspectors should be to point out to servants the manner in which they endanger their own health, and that of the families in which they live, and to inspire them with a wish to improve. This could only be

done by a lady superior to themselves in education and position, and with whom the masters and mistresses could confer on an equal footing.

**SERVANTS' CLUB.**—The Working Men's Club and Institute Union offers a prize of £5 for the best essay on Servants' Clubs. The competitions are expected to relate the history of these clubs, to point out the evils which prevail in them, and suggest means for placing them on a better footing. The Earl of Shaftesbury, the Rev. Henry Solly, and Mr. Hodgson Pratt, have accepted the office of adjudicators, and all essays must be sent in by the 31st of May. Authors in search of a subject may be inclined to contribute their mite towards the elucidation of an important social topic, and if the prize offered seem a modest one, it may yet be satisfactory to the winner to hope that he has suggested some method of promoting a better understanding between servants and their employers.

**WIGHT v. WIGHT AND FIELD.**—The question of costs in this case was brought before the court on the 24th ult. The respondent has to pay costs, and the co-respondent his own costs in the second trial. Now that litigation is over, the expenses incurred by Mr. Field in successfully vindicating his character will soon be ascertained. The fund being raised by his professional brethren and friends is going on favourably, as will be seen by the list we publish in another column. It affords us much pleasure to observe the unanimity of feeling in this cause.

**HANCOCK v. PEATY.**—This extraordinary case has come to a conclusion during the past week. In withdrawing from further proceedings, Mr. Peaty allows his marriage to be pronounced invalid, and the case altogether continues in the same obscurity as before.

"On the 24th ult., Dr. Spinks, Q.C. (with whom was Mr. Searle), for the respondent, stated that although Mr. Peaty still retained his own private opinion as to his wife's sanity, and was still anxious that they should continue to live together, yet as her present medical attendant was not able to give a certificate that in his opinion she was competent to manage her own affairs, Mr. Peaty had determined not to make any further opposition to the decree. He came to this conclusion with regret and by the advice of others, but he thought that he should not be justified under the circumstances in prolonging the suit.

"The Judge-Ordinary accordingly pronounced a decree of nullity."

All, therefore, that the Profession learns further of the case is, that her present attendant hesitates to pronounce her sane.

**AUSTRALIAN BEEF.**—The Society of Arts Committee upon the food of the people, has lately had under its notice an article to which we would draw attention. It is fresh beef that can be sold retail at 7d. per lb. *without bone*. It is to be had in tins of 6 lbs. each, and the only peculiarity of it is that it seems a little over-cooked. There is nothing novel in the process of curing it; the only reason it can be sold at half the cost of English beef is, that in Australia there is so plentiful a supply of oxen, and rearing them is so inexpensive. Soups, beef-tea, and other preparations made from this beef have been pronounced equal to any, and we may consequently hope that the poor may be enabled to increase the amount of their animal diet in spite of the high prices that have lately prevailed for meat. Charitable institutions will also do well to make a trial of this importation.

## ON THE PURIFICATION OF WATER: A NEW METHOD.

DURING the year 1866 we had afforded us an opportunity of judging of the quality of the water supplied for consumption to the inhabitants of the metropolis. At no more appropriate period, perhaps, could the labours of Drs. Letheby and Frankland have been given in the cause of public welfare, and the results have served to develop a very important epoch in the history of cholera.

We may state that from circumstantial evidence, impure water of a certain description was the main feature co-existent with the progress, and its purification with the restriction of the choleraic epidemic.

So soon as it was ascertained that without doubt impure water, such as we were once supplied with, was a cause of originating disease, and that further demand, necessitated by the increasing population, was not met by an adequate supply, many schemes were set about for remedying these evils. The importation of entirely fresh supplies from more than one source was suggested. The collection of rain-water; taking our supply from higher up the Thames; from deep artesian wells, and the purification of our present supply by diverse schemes. As the water for domestic and manufacturing purposes requires freedom from impurities, differing from those necessitated for dietetic use, more than one suggestion embodied the idea of dividing these, and obtaining the two from different sources.

The estimates furnished ranged widely, one being as much as 25 millions sterling.

To sum up briefly the design of these various schemes—they are nearly all very costly; contemplate a considerable lapse of time before any benefit can be derived from them; and substitute an entirely different article from that with which we are now supplied. Those that propose the utilization of the present supply, are of course excepted in the latter instance. There is no doubt a better quality of water than our present is not only desirable, but necessary, and the best means of procuring such is worthy of consideration. Is it desirable, however, that we should discard our present supply, and seek an entirely fresh source freer from impurity and more fitted for consumption? It is possible to reply in the negative, and substantiate reasons for so doing. As to one of the foregoing schemes, according to the analysis of Professor Way, the water from the Cumberland Lakes is far superior to London water in point of freedom from foreign bodies. The former gives 4.69 grains per gallon, of which .59 grains is organic matter, and the latter averages 20.57 grains per gallon, including 1.01 grains organic matter. But these results are not absolute in their indications of quality, they must be taken in consideration with other circumstances. The average amount of impurity or residue naturally found in good potable and wholesome water is from 17 to 23 grains per gallon, according to the best authorities, Dr. Taylor amongst others.

In analyses performed by Professor Chandler, of New York, of seventeen samples of water obtained between Syracuse and Rochester on the New York Central Railroad, the average was 20.57 grains per gallon, and although we often find samples differing from these limits, 1.3000th to 1.4000th is the amount of impregnation nature furnishes as a standard. Is this solid residue then extraneous to the reaction of the water on the system; or, on the other hand, necessary for constituting and restoring the waste of the bony structure of the frame, and enriching and purifying the blood? In all probability the latter. Independent of this, however, we have been accustomed, since endowed with life, to consume, and exist upon aliment, amongst others, that contains 20.57—70,000 of salts and earth with other impurities. It is no uncommon occurrence to find change of locality prejudicial to individuals, and sometimes perceptibly owing to the difference of water consumed. These are points that require something more than theory for their solution. Organic matter is the doubtful substance that we cannot see. It may be present without impairing the quality of the water, but more often it is

otherwise. We have no certain test capable of generalization that will determine the amount of evil in any sample of organic constitution brought under notice, and therefore it is safe only in rejecting all alike. Owing to generation and decay of this substance its quantity cannot be taken as constant, and the variation generally depreciates the quality.

There is another suggestion for supplying water to the metropolis. It proposes to utilize the present supply by purification—1st by precipitation of earthy salts and sedimentary matter, and 2nd by organic oxidation to reduce the hardness and contamination to its minimum; and to perform these operations on the existing works, now occupied by the water companies, and these operations are proposed immediately before actual consumption, and thus a preventative is insured against spontaneous organic generation.

For a continuous supply of water, two similar reservoirs, or one reservoir divided into equal parts, is constructed without any filtering medium whatever, but simply acting as a store. At a small distance above the bottom sufficient to avoid sediment, outlets are provided, guarded by sluices that can be opened at desired intervals. Under the reservoir a space about seven feet in depth is constructed extending under the whole area, and on the floor of this a bed of animal charcoal, twenty-six inches or three feet thick, is provided. This chamber is in direct communication with the supply-pipes to the various localities. By means of the arrangement access may be easily obtained to renew or cleanse the medium of filtration without disturbance to the working, and it also affords free admission of fresh air, and the escape of foul gas evolved from the filtering body. Near to the reservoirs is an apparatus through which the water is supplied. It is constructed on a self-acting principle to embody Dr. Clark's methods of extracting hardening matter by precipitation. This completes the entire arrangement of the system. The water first, by passing the softening apparatus, precipitates with the earthy salts all sedimentary matter, and, as has been found by experiment, much organic contamination in the reservoir. As this requires an interval of time, the reservoir is divided as described into two sections, one remaining undisturbed while the water is being introduced into the other. When clear, which generally takes place in the course of an hour or little more, the sluices are allowed to conduct the water at once into contact with the animal charcoal which, to this time, has remained free and exposed to the atmospheric air, to evolve any gaseous impurities previously imparted to it, thence by rapid filtration it enters the supply to the mains, precaution being taken to prevent any charcoal being mechanically carried with it. The filtration, it will be seen, is performed by the alternate use of two media. In practice, this is necessary for the precipitation of the mechanical impurities, and the ventilation, if we may so allude to it, of the oxidizing medium. The same system is applicable to any magnitude, and an apparatus for embodying the idea, specially intended for manufactures, has been introduced. Even to house-cisterns, with a small amount of care, it is possible to apply it. According to an analysis and report recently made by Dr. Letheby, new river water, after passing through such an apparatus, contains 19·98 grains of solid matter per gallon, of which 0·52 grain is of oxidizable organic matter, and 15 grains of hardness. After passing through the apparatus it is reduced to 8·89 grains of solid matter per gallon, of which 0·12 grain is oxidizable organic matter, and 6 grains hardening salts. The report proceeds to state that—"By the subsequent filtration of the water, the organic matter was almost entirely destroyed. This was proved not merely by the chemical tests to which the water was subjected, but also by the snow-like appearance of the saline matter obtained on evaporation." The results approach those obtained on analysis by Professor Way of the water from the Cumberland lakes already referred to. The expense of applying this system is nominal, taking into comparison most of those before the public, and possesses the advantage of utilizing the present supply. The proposer of this method, and patentee of the apparatus, is Mr. T. W. Tobin of 8, Old Jewry, E.C.

### "CORK AS A SEAT OF LEARNING."

*"Daily Southern Reporter,"*  
"Cork, 27th April, 1867.

SIR,—My attention has been directed to some remarks in THE MEDICAL PRESS AND CIRCULAR of the 24th inst., which seem to impute to Professors Corbett and Tanner the writing of certain paragraphs in the *Reporter* of the 13th inst. You have been uncourteous not only to those gentlemen but to this paper also, and without any grounds whatever. I have had sufficient experience at the press to entitle me to decline being instructed by you in the duties of a journalist. I cannot admit your right to question the propriety of publishing those 'pseudo-editorial articles,' as you are pleased to call them.\* As I desire, without dragging the names of those eminent gentlemen into a newspaper controversy, to remove immediately the imputation you have unwarrantably cast on them, I depart from the usual course, and take the liberty of addressing you, in order to inform you that I wrote and published the paragraphs in question, without the knowledge or cognizance in any way, direct or indirect, of either Dr. Corbett or Dr. Tanner. Being personally aware of the facts, I conceive I had a perfect right to make them public. Both those gentlemen are, therefore, innocent of the charge which you imputed to them. Your sense of justice will suggest to you the necessity of your withdrawing it; and, I request, you will do so in a manner equally prominent to that in which it was put before your readers.—I am, sir, yours,  
D. F. BUCKLEY."

[We cheerfully transfer the responsibility of the editorial puffing of Professors Corbett and Tanner to which we called attention in our last, from those gentlemen to our correspondent, premising that it is a manifest misrepresentation of our observations to impute to us any charge against these gentlemen. We expressed a hope and belief that these paragraphs would be found to be the work of an injudicious friend. Although the articles in question have not been personally repudiated by either of the gentlemen to whom they referred, we presume we may attribute the irate mood of our correspondent to a very vigorous remonstrance from them. We have simply to remark that, if the editor had reason to imagine that the publication of these puffs would be distasteful to the feelings of Professors Corbett and Tanner, as their professional rank would lead us to anticipate, he acted with unaccounted indiscretion in publishing the rhapsodies, and those gentlemen owed it to their Profession, as much as we ourselves did, to elicit a disclaimer of their having countenanced, even in the remotest degree, so unprofessional a course.—Ed. M. P. & C.]

### THE RECENT POOR-LAW INQUIRY.

The following is the letter received from the Poor-Law Commissioners, and read at the last meeting of the Board of Guardians of Limerick Union:—

Poor-Law Commissioners,  
Dublin, 11th April, 1867.

SIR,—The Commissioners for administering the laws for Relief of the Poor in Ireland, transmit to you herewith for the information of the Board of Guardians of Limerick Union the minutes of evidence taken by Mr. Bourke, at an inquiry which he held in pursuance of instructions from the Commissioners, on the 2nd instant, and several subsequent days, into charges against Dr. O'Sullivan, resident medical officer of the Work-house, and Miss Gerraghty, the storekeeper, which are contained in a report of a committee of the Board of Guardians appointed to investigate the state of discipline in the hospital department, and of the establishment generally. The charges against Dr. O'Sullivan may be stated as follows:—

1. Insubordination to his superior officer, Doctor Brodie.
2. Irregularly ordering extra diets to patients in hospital,

and stimulants and beef-tea to inmates not on the medical books, as well as to officers during illness.

3. Neglecting to compound medicines, and leaving medicines to a wardman to be administered to patients as ordered on admission.

4. Omitting to keep the hospital book himself, and delegating that duty to an irresponsible person.

5. Disrespectful conduct and language towards the Sisters of Mercy, and obstructive interference with arrangements.

6. Disrespectful conduct and language towards the matron.

7. Excessive familiarity with Miss Gerraghty.

8. Disrespectful conduct towards the Committee.

The evidence as to the first charge appears to have exclusive reference to circumstances which took place in 1865, and which were at that time fully disposed of, and it is stated by Dr. Brodie in his evidence that the only instance of insubordination on Dr. O'Sullivan's part towards him since 1865, was about the time, or shortly after the time of the discussion of the subject of their duties, and that since then there has been no repetition of it, and they have acted harmoniously. In support of this charge reference is made to the fact of Dr. O'Sullivan having re-admitted to hospital three members who had been discharged from it shortly before by Dr. Brodie; but it will be seen on reference to Dr. Brodie's evidence that he entirely relieves him from all blame, and is of opinion under the circumstances that Dr. O'Sullivan was quite right in re-admitting them.

The second charge seems to be in some degree connected with the first, as it appears to have been considered that Dr. O'Sullivan had been directed not to order extras without the sanction of the senior medical officer. No evidence of the existence of such a direction had been produced, and Dr. Brodie states that there is nothing objectionable in Dr. O'Sullivan's conduct as far as he knows, or has heard of it, in reference to the administration of wine or spirits, to patients or officers, and it will be seen that there is evidence of special and exceptional circumstances in each of the cases brought forward as instances in which stimulants or extras have been ordered for persons not on medical books.

The portion of the third charge which alleges neglect to compound medicines is explained by the fact that Dr. O'Sullivan appears to have been permitted to take apprentices, who have been employed by him, when fully instructed, and, in his opinion, competent to assist him in the discharge of his duty, and in regard to the leaving medicine with a wardman to be administered, Dr. O'Sullivan explains that he occasionally orders cough bottles to patients on admission, or astringent mixtures, or things of that sort, and that he leaves a small supply with the wardman to be administered as directed on the admission sheet, but that his directions thus given are confined to ordinary sorts of medicines, and to patients newly admitted, and he is satisfied that they cannot prove dangerous.

The practice in regard to keeping the Hospital books appears to be that which was in force when Dr. O'Sullivan was appointed, with the exception that the record of sickness and mortality formerly kept by Miss Supple is now kept by Dr. O'Sullivan.

In support of the charge of disrespect towards the Sisters of Mercy and obstructive interference with their arrangements the testimony of several witnesses is produced. It is shown by Dr. Parker that complaints on this head were made as far back as June, 1865, and Miss Butler, one of the sisters, states that the conduct complained of has continued up to the present time. Instances of the alleged unnecessary interference are given, the most recent being the proceedings which took place in the month of December last, in reference to the use of buckets in the sick wards at night. Several witnesses deposed to expressions more or less hostile and disrespectful, and some of them to the use of profane and coarse language in reference to the sisters. The existence of a rebellious temper on the part of some of the male patients, and hesitation on the part of the assistants is attributed to his interference. On the other hand, Dr. O'Sullivan produced witnesses to speak as to his respectful demeanour, and denies the use of the language attributed to him, and explained the circumstances under which he ordered the removal of the buckets, and which, in his judgment, rendered their removal desirable and necessary. He also explains the grounds of other directions given by him in his capacity as medical officer in charge of the hospital, which are adduced as instances of interference with the arrangements of the Sisters of Mercy. The charge of disrespectful conduct towards the Matron appears to relate to matters which occurred long since, and although the language stated to have been used by Dr.

O'Sullivan to the Matron was objectionable and improper, the charge does not appear to be one of a very grave character.

The evidence in support of the charge of disrespect towards the Committee shows that Dr. O'Sullivan's language and demeanour to the Committee were such as cannot be justified, and appear to evince a hasty and ungovernable temper.

The charge of familiarity with Miss Gerraghty is fully sustained by the evidence of many witnesses, and is not contradicted; and while the evidence does not afford any ground for suspicion of any immoral conduct, it clearly shows that the association has been such as to be highly imprudent, and calculated to produce, as it has done, gossip and scandal in the Workhouse, and to have an injurious effect upon the order and discipline and general moral tone of the Workhouse.

In regard to the charges against Miss Gerraghty, there is evidence of her having been heard to make use of angry and disparaging expressions in reference to the Sisters of Mercy, and her intimate association with Dr. O'Sullivan is shown in the evidence already adverted to. No defence on either of these points has been offered by her.

Upon the whole it appears to the Commissioners that while many charges relate to transactions long since inquired into and settled, some of them have not been sustained, and the testimony of Dr. O'Sullivan's conduct and efficiency as a medical officer of the workhouse is of a very high character. Dr. Brodie states in his evidence that he always found Dr. O'Sullivan competent, attentive and successful; and Mr. M'Terney, the late master of the Workhouse states that he does not think any one could have been more careful in discharging his duties, and that he always found him ready to carry out everything he desired in the house.

Were it not for the great imprudence exhibited by Dr. O'Sullivan in language used by him in the presence of inmates, regarding the Sisters of Mercy, and in his intimate and familiar intercourse with a subordinate officer of the workhouse, and in the continuance of that intercourse after it had been made the subject of a formal inquiry, the commissioners think that the union would have benefited greatly by the retention of his services; but after the unanimous expression of opinion of the Board of Guardians against both him and Miss Gerraghty, the Commissioners think that both those officers will act for the best in resigning their respective offices, a course which will not have the effect of rendering either of them ineligible for service under the poor-law elsewhere.

The Commissioners request that the enclosed minutes will be returned when done with,

By order of the Commissioners,

B. BANKS,  
Chief Clerk.

## Correspondence.

### MR. THOMPSON'S REPLY TO DR. CAPLIN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—As Dr. Caplin, in his reply to my letter, has expressed his happiness to hear from me again, I proceed to answer him, and will take up his objections seriatim.

In the first place, he accuses me of not appearing to understand him. This accusation I do not consider of much importance, considering that he was sufficiently obscure in his communication, which appeared in your journal, to leave me in a state of doubt.

Dr. C. thinks it *desirable* that ridiculous theories should be propounded. I agree with him that it is not wonderful but merely simple and natural that they have been, are, and will be, promulgated, but, in my opinion, I think that they are not at all to be desired or sought after.

If ridiculous theories were not propounded, Dr. C. says that man's intelligence would remain at a stand-still, and science make no progress. I am sorry here again to pause and disagree with him. I think that man's intelligence would be more successfully cultivated, and science make more rapid strides towards the discovery of truth, if there were no such restraints as pet theories, or absurd conceits, or hobby-horses, or coloured spectacles in existence at all.

Dr. C. does not clearly see that I have the right to assume the position of a critic. I believe that I have a perfect right to criticise any communication which appears in the public prints; if not, why not? Are the results of experiments,

cases, &c., which are published in the medical journals, not open to criticism? I was always under the impression that they were. Perhaps I am wrong, but I believe that every man who brings before the public any communication, of whatever nature, is open to criticism. If I misunderstood Dr. C., it was his duty to set me right, without informing me that I had no right to criticise his theory—this addition was altogether unnecessary and superfluous.

Dr. C. says that he has laboured for thirty years, and implies that I think he has been mistaken during all that time. I don't think anything of the kind. It is not the results of his experiments I attack, which, if the experiments themselves have been conducted accurately, can lead to nothing else but true results, and will, therefore, be incontrovertible facts, but it is his theory which I think he makes rather *universal*, and which I object to, and with which I have to do.

Dr. C. talks of Pythagoras, Galileo, Harvey, and Jenner. What relation they have to the subject under discussion, I am unable to see, or what he wants to prove from the short extracts that he gives concerning them, I can't for the life of me understand.

The point about which I was in doubt, Dr. C. has cleared up by telling me that I was quite correct in supposing that he would put electricity in the place of what Hunter called the "materia vitalis," or Müller the "organic force." Only he would term it the "vis universalis," since, in his opinion, all the phenomena of the universe—vegetable and animal—owe their life to this subtle fluid, which is everywhere, and permeates all created nature. Now, I believe this is only another erroneous theory which Dr. C. will get the credit of contributing to the already too voluminous store of absurd conceits; and hereafter Dr. Caplin's "vis universalis" may be talked of in the schools, and enumerated among the other theories which have been long since exploded, and consigned to oblivion.

I am very well aware that no decomposition takes place in nature without the evolution of electricity, and that, when it is evolved, it is capable of being put to a useful purpose, and acting as a power. So far, I agree with Dr. C. that it is effect and cause, and cause and effect; but the real point at issue between Dr. C. and myself is that he maintains that it is effect and cause, and cause and effect, in the *human body*. I agree with him that it is an effect of the chemical and chemicovital processes which are continually taking place in the animal body; but I totally demur to the assertion that it is also a cause of any process whatever which takes place in the human system.

I may be wrong, and Dr. C. right, but I think myself perfectly justified in being a little incredulous as to Dr. C.'s assertion until the proof be forthcoming.

Let Dr. C. only prove that any process, however trifling, takes place in the human body as a result of electricity, and I will rest satisfied, and be very much obliged to Dr. C. for instructing me on this point.

If I at any future time happen to be in Dr. C.'s neighbourhood or vicinity, I will favour him with a visit to his establishment, and will feel grateful and obliged to him for his courtesy and kindness, and will, I have no doubt, profit by the visit.

In conclusion, I have only to thank Dr. C. for his letter, which does not seem to be written in a spirit of animosity, nor is it interspersed with invective or inuendo, but to be composed in a cool and collected manner.—I remain, sincerely yours,

GEORGE WM. THOMPSON.

#### LICENTIATESHIP OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Through the medium of your excellent paper, I should wish to ask the President and Fellows of the King and Queen's College of Physicians, is it allowable for those possessing the License of that College to sign themselves members of it? It has been explained in your journal of April 3rd, that the Licentiate's degree in the Colleges of Physicians of London and Edinburgh is almost equivalent to a membership of Apothecaries' Hall, and that those possessing it can make up medicine, and sue for it under the "Tradesman's Act." Now, in the King and Queen's College of Physicians of Ireland, after each candidate passes his examination, and before he receives his License he is required to make a declaration to the effect that he will not compound medicine or engage in trade in any part of the United Kingdom. Under these circumstances surely a Licentiateship of the Dublin College is equivalent in rank to a membership of the London and Edinburgh

ones, and being so, why do not we Dublin Physicians enjoy the same title as our English and Scotch brethren?—Yours truly,  
M. ? K. & Q.C.P.I.

[Our Correspondent is slightly in error as to the terms of the declaration subscribed by candidates for the license of the King and Queen's College of Physicians in Ireland. The candidate declares that he will not compound or dispense medicines *for sale*; but there is nothing to hinder him supplying medicines to his own patients, provided he does not charge for them. There is just one reason why a Licentiate of the K.&Q.C.P.I. cannot call himself a member, and that is because it would be illegal to do so. The Charter of William and Mary confines membership of the corporation exclusively to the Fellows; and not only so, but it limits the number of Fellows to *fourteen*. Lucas's Act, I. Geo. iii., cap. xiv., while removing the limitation as to numbers in the case of the Fellows, expressly speaks of them, and of them only as "members." It is even so as regards membership with the Royal College of Surgeons in Ireland, whose present Fellows correspond to the "members" under the original charter of that body. The distinction between the Licentiate of the K.&Q.C.P.I. and the Licentiate of either of the other Colleges of Physicians, and the analogy between the License of the Dublin College and the Membership at London and Edinburgh, are so well understood by the Profession, that our correspondent need have no fear on these heads.—ED. M. P. & C.]

#### "BLACK DEATH."—DR. BENSON'S CASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR—In your last issue, my friend Dr. Benson published an interesting case of that prevalent and fearful malady, commonly called "Black death." He has ably described his patient's morbid condition in life, and the post-mortem results. I beg, however, to take exception to some of his conclusions, in which I feel concerned. In his summary of the case he says: "To the theory of those who are of opinion that this disease is connected with cerebro-spinal meningitis, this case at least lends no support." The theory referred to was, I believe, *first* advanced by me in connexion with a case of "Black death," which I inserted in your excellent paper of June 13th, 1866. This theory has found favour with many, and with some has been made a basis of treatment, the only real value of any theory. But it appears to me that Dr. Benson's case as reported by himself, proves, in a remarkable degree, "a connection of the disease with cerebro-spinal meningitis." How otherwise can we explain those symptoms of his case. The patient "was dull, drowsy, and stupid;" "did not answer when spoken to;" "his fists were clenched;" "had considerable jactitation;" "had twice . . . a convulsion." Again, observe the post-mortem appearances after those symptoms. "Rigor mortis rendered the extremities quite rigid;" "the dura mater presented an unusually bluish tint;" "its sinuses and veins were unnaturally distended;" "veins on the surface of the brain a good deal congested;" "brain slightly softer than is natural, but scarcely congested;" "a drachm of bloody serum" in each lateral ventricle; "choroid plexus congested." "The spinal cord presented appearances similar to those of the brain;" "sinuses very much congested;" veins on the surface of the cord turgid throughout."

The absence of meningeal adhesions and thickening, adventitious membranes and effusions, are not necessary to prove the existence of meningitis, which precedes, and may create these products, should the patient survive long enough. In this case, as in mine, I am of opinion death resulted not from meningeal inflammation, but from capillary congestion and hemorrhage, and this from the loss of power of the vasi motor nerves, the cerebro-spinal overbalancing them. I remarked in my paper that implication of the cerebro-spinal and sympathetic systems formed a prominent and early feature in the disease.

I agree with Dr. Benson that the term "black death" is appropriate to the present disease, so far as the fatality and the blackish spots identify it with the "black death" of the middle ages. In my case, however, there was another point of similarity—namely, bloody expectoration. In Dr. Benson's case, this condition might have arisen had the capillary effusion been greater during life, as the post-mortem showed. "On the surface of the lungs, and throughout their substance, were found numerous well-defined black spots of the character of punctiform melanosis. There was slight congestion of the lungs."

Dr. Benson is inclined to class this strange malady with "malignant purpura." I am disposed to adopt Dr. Lyons' opinion, who defines it as, "the algide stage of an essential

zymotic febrile condition, the further development of which is as yet undetermined; and, with cholera sicca alone can it be compared."

Several cases of this alarming disease preceded the recent outbreak of cholera in this country, and may we hope the cases now occurring do not presage a renewal of that scourge, or of some kindred visitation.

Hoping the foregoing remarks may elicit further useful enquiry upon this important subject, and with thanks for your invariable courtesy to me.—I am, faithfully yours,

P. C. LITTLE, F.R.C.S.I., &c.

#### OINTMENT OF IODIDE OF POTASSIUM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the "Report of the Progress of Pharmacy," at page 407, in your last number, under the above heading, it is stated "Mr. Mohr proposes to prevent the brown discolouration of ointment of iodide of potassium, by adding hyposulphite of soda to the ointment." I think a question arises, which it would be well to have answered, as to the probability of the efficacy of the ointment being neutralized as well as the colour.

It is well known that by the combination of tincture of iodine and a solution of hyposulphite of soda (called the "iodine process") the ink-like stains of nitrate of silver may be eradicated. Chemically, the hyposulphite of soda neutralizes iodine; whether medically it has the same effect, is a question for your readers to answer.—I am, sir, your's very truly, CHEMICUS.

#### NURSES' TRAINING INSTITUTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

152, St. James's-street, April 27, 1867.

SIR,—Will you allow me space to make known that in consequence of a change of Superintendents of the above Institution, all applications for nurses are at present to be made to Miss Harricks, 152, St. James's-street.

One of the nurses belonging to the Institution has lately been employed for twelve weeks under Dr. Butcher, President of the Royal College of Surgeons, in nursing a severe surgical case, and has returned to the Institution with the highest testimonial from him. He writes—"I willingly recommend her to others, as I do not think a better nurse could be procured."—I remain, sir, your obedient servant,

THOMAS COOKE TRENCH, Hon. Sec.

#### ON THE THERAPEUTIC ACTION OF HENBANE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reply to a query from one of your correspondents in your number of the 20th of March last, who represents himself as in a dilemma respecting the properties of hyoscyamus, I beg to say that I am of the opinion of those who consider it to be one of the best narcotic sedatives that we possess, though others seem to attribute to it no therapeutic action whatever.

I have myself employed it with great advantage on many occasions. The only question to ascertain is whether the samples possess the virtues and qualities of the herb. We all know that medical organic or vegetable substances lose their properties sooner or later. Hyoscyamus is one of those which become deteriorated the soonest—the component parts being in many circumstances disintegrated; while, on the other hand, if the herb is not gathered in the proper season, that is just when it is at maturity, and before the evolution of the sap begins to progress downwards, it may retain little or no virtue at all. Its properties may be annihilated again if it is not properly dried before chemical decomposition has taken place; and even when carefully prepared, either in the shapes of extract or tincture, it appears that the preparations become inert in the course of six months.

Rupus Usher, Esq., a grower of medicinal herbs, informs us that he has paid special attention to the cultivation of the henbane which grows in Europe. He says that there are many varieties of the herb; but that the German species, though so fine in appearance, possesses very little or no medical property. The English one, however, is possessed of all the therapeutic qualities which characterise this medicament, if gathered in due time, and properly preserved.

Henbane is a biennial plant, which acquires still stronger properties in the second year of its growth. The best means of appreciating its virtue is by its flavour and aroma, which, in reality, constitute its influence as a medicine upon the nervous system.

It appears that in America, where both the soil and tem-

perature are more favourable for the development of all kinds of plants, that hyoscyamus enjoys amongst others the privilege of that country.

Dr. W. Beach, who has published a volume of pp. 600 on Medical Botany, describes the properties of henbane as follows:—"It is a strong narcotic, very poisonous, and often proves fatal when taken by mistake. The symptoms produced by an overdose are, giddiness of the head, great thirst, dimness of sight, raving convulsions, risus sardonicus, coma, &c.

"Dr. B. S. Heath, an authority well entitled to respect, read a very interesting paper before the National Eclectic Medical Convention of 1848, upon the therapeutical properties of this plant, the substance of which we extract from the *Western Medical Reformer*. He states that he had been prejudiced by his early medical education against the use of all narcotics, but had recently adopted eclectic principles, and found that narrow proscriptive theories were not adapted to Medical practice." He also mentions seven cases in which hyoscyamus was used with the greatest success:—

1. A Thompsonian practitioner, who was suffering severely from asthma, and could not be relieved by all the resources of Thompsonianism, was alleviated in ten minutes by the exhibition of the extract.

2. A case of pleurisy, accompanied with violent pains and difficulty of breathing, completely relieved in two hours by the same, and hot fomentations of the plant.

3. A severe attack of pleurisy with pungent pain, in a farmer, aged fifty, relieved and cured by the same.

4. A case of severe pain, irritation, and restless wakefulness in a lady, two weeks after accouchment, relieved in three hours, by doses of half-a-grain, once every hour.

5. A case of violent pain and muscular spasm, which had resisted all other means, was frequently relieved by hyoscyamus, in from thirty to sixty minutes.

6. In a similar case of sleeplessness for seven days and nights, the henbane gave relief.

7. In several severe cases of after-pains, it was also very successful.

Dr. Heath dissolves twenty grains of the ext., in  $\bar{v}$ iv. of water, and gives one or two teaspoonful every ten or fifteen minutes, discontinuing it as soon as the pain is abated. This he uses in all cases accompanied with pain, either inflammatory or spasmodic.

Employed *externally*, or in the form of a poultice or fomentation, it is beneficial in all cases of painful or obstinate inflammation, such as fistulas, boils, swellings of the breast, scrofulous ulcers, indolent tumours, inflamed eyes, and cramps in the bowels. In deep-seated inflammation of the kidneys, bowels, testicles, &c., this poultice is very useful, and seldom fails to produce a beneficial result. Indeed, no better application can be found for many painful affections.

So far we have the testimony of a gentleman of great experience and extensive knowledge. Dr. Beach has travelled amongst almost all civilized nations, and visited all the Hospitals as he went through. He has been honoured with fifteen medals, by the Sovereigns of the various countries which he has visited. Among his literary contributions he has published his great work, in three large volumes imperial 4to, of pp. 1200 each: the one on Botany, one on Medicine, and the third on Surgery, which is a proof of the extent of his researches in medical science, and of the authority to which he is entitled as a master.

We find again very valuable references and instructions in a work published at New York by Grove Coe, M.D., on the "Concentrated Organic Medicines, and Official Preparations" of B. Keith and Co., chemists of great eminence, who have undertaken to ascertain, by decomposition, the elements which constitute the virtues of medicinal plants, separating them by a new process of analysis and synthesis. They have thus acquired a superior knowledge of the compound substances and the properties of organic medicines.

These preparations, which have lately been introduced into London, are not as yet adopted in the "British Pharmacopœia." It is to be hoped, however, that the time will come when they will be received in general practice, and that the profession will become better acquainted with their value.

Dr. Grove Coe, who has experimented upon all the pharmaceutical preparations of Messrs. Keith, gives the exact value of every medicinal substance. What he says respecting henbane, confirms so exactly the description I have given above of the properties of that plant, that I need not repeat it. Enough has been said to establish the value of this precious remedy as a narcotic, when duly prepared from genuine sources.

I have alluded, in the above remarks, to the eclectic American practice, a system, which, in my humble opinion, is not sufficiently appreciated. My reason for thinking so is founded upon the belief that nature has provided the vegetable kingdom, which is organic, for the formation, the development, the restoration and healing of the organism of the animal kingdom.

In my reply to Mr. Thompson, of this week, I observed that we should not discard any kind of system, without having first given it an unprejudiced and careful investigation. Is man to stand still in his researches? Can we philosophically admit, that we have arrived at a perfect standard of medical knowledge, and that we have nothing more to attempt for the future? We have the English *materia medica*. Is this perfect? We have in France the *codex*. Is that more complete? We have in Italy Rosari's system (the best no doubt for appreciating the general characteristics and *modus operandi* of medicinal agents)—but is this perfect?

The work published by Dr. Giacomini on that subject, in French, seems to be unknown in this country. Why should we confine ourselves to the region of our birth?

Socrates used to say—"I am a citizen of the whole world." Why should not medical men be the same, as the whole earth belongs to every single inhabitant of it?

I shall conclude with a quotation from Dr. Bover Dodd, of America (the author of the "System of Psychology"), who says:—"The best system is that one which is composed of the best of every system."—I remain, sir, yours faithfully,  
J. CAPLIN, M.D.

## Medical News.

**UNIVERSITY OF LONDON.**—The Senate of the University of London elected the following gentlemen as examiners for the year 1867-68:—

**Classics.**—F. A. Paley, M.A., and William Smith, LL.D. Mathematics and Natural Philosophy.—Edward John Routh, M.A., and Isaac Todhunter, M.A., F.R.S. The English Language, Literature, and History.—Rev. Joseph Angus, D.D., and Christopher Knight Watson, M.A. The French Language.—Rev. F. H. Ernest Brette, B.A., B.D., and Theodore Karocher, LL.B. The German Language.—F. Althaus, Ph.D., and Prof. Buchheim, Ph.D. The Hebrew Text of the Old Testament, the Greek Text of the New Testament, the Evidences of the Christian Religion, and Scripture History.—Rev. J. J. Stewart Perowne, B.D., and William Aldis Wright, M.A. Logic and Moral Philosophy.—Professor Alexander Bain, M.A., and Edward Poste, M.A. Political Economy.—William B. Hodgson, LL.D., and Professor Jacob Waley, M.A. Experimental Philosophy.—Professor R. B. Clifton, M.A., and Professor G. G. Stokes, M.A., D.C.L., Sec. R.S. Chemistry.—Henry Debus, Ph.D., F.R.S., and Professor A. W. Williamson, Ph.D., F.R.S. Botany and Vegetable Physiology.—Rev. M. J. Berkeley, M.A., and Thomas Thompson, M.D., F.R.S. Geology and Palaeontology.—Archibald Geikie, F.R.S., F.G.S., and Professor T. Rupert Jones, F.G.S. Law and Principles of Legislation.—Professor Mountague Bernard, B.C.L., M.A., and John Richard Quain, LL.B. Practice of Medicine.—Professor Edmund Alex. Parke, M.D., F.R.S., and Samuel Wilks, M.D. Surgery.—Frederick Le Gros Clark and Professor John Eric Erichsen. Anatomy.—Professor George Viner Ellis, and Professor William Turner, M.B., F.R.S.E. Physiology, Comparative Anatomy, and Zoology.—Professor Thomas H. Huxley, Ph.D., F.R.S., and William Scovell Savory, M.B., F.R.S. Midwifery.—John Braxton Hicks, M.D., F.R.S., and William Overend Priestly, M.D. *Materia Medica* and Pharmaceutical Chemistry.—Frederick J. Fære, M.D., and Samuel Osborne Habershon, M.D. Forensic Medicine.—E. Headlam Greenhow, M.D., and Thomas Stevenson, M.D.

**ROYAL COLLEGE OF SURGEONS, LONDON.**—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College, at a meeting of the Court of Examiners on the 25th ult., viz:—

Messrs. James Wood Cooke, Barnstable, Devon; Joshua William Morison, Pembroke; William Calvert, Toulmin, Lower Clapton; Arthur Bowles Elliott, Richmond, Yorkshire; Benjamin Duke, Kennington-park-road; Charles Munden, Ilminster; Edward Sunderland, Thornton, Yorkshire; William Jebson Stothard, Manchester, and Charles John Walford Meadows, L.S.A., Otley, near Ipswich, students of Guy's Hospital; Alfred Henry Newth, Albert-street, Newington; Nelson Congreve Dobson, L.S.A., Holbeach; Alfred Peon, L.S.A., Winchester, and William Anderson, L.S.A., Stockwell, of St. Thomas's Hospital; Frederick Augustus Alfred Smith, Cheltenham; William Henry Causton, Woodbridge, Suffolk; and Richard Careless Sanders, L.S.A., Moulton, Northampton, of the London Hospital; George Percival Hadley, Birmingham; Henry Flammank Marshall, Birmingham, and John Orton, Foleshill, near Coventry, of the Birmingham School; Walter Smith, Hampton Court, and Octavius Twigge Molecey, Stamford, of King's College; Richard Augustus Rouse, Great Torrington, North Devon, of University College; Christo-

pher William Calthrop, Withern Alford, Lincolnshire, of the Charing-cross Hospital; Frederick William Newcombe, Newcastle-on-Tyne; John George Nevitt, Leeds, and Thomas Bartholomew Tracy, M.D., Queen's University, Canada, Kingston, Canada.

The following were admitted on the 26th ult.:—

Messrs. Thomas Andrew Roberts, Shaftesbury; James Goodridge Anderson, L.R.C.P. Lond. and Edinb., L.M. and L.S.A., Theddlethorpe, Lincolnshire; William Henry Wood, Woodhouse Eaves, Leicestershire; and Henry Franklin Parsons, L.S.A., Beckington, Somerset, students of St. Mary's Hospital; Alfred Henry Buck, Camden-town; William Powell, L.S.A., Shirley, Southampton; Adam Wilkinson, L.S.A., Shaftesbury, and John Levitt Davis, Euston-road, of the Charing-cross Hospital; Edmund Wollaston Parkinson, Shere, near Guilford; Philip Henry Mules, Cheddar, Somersetshire; Frederic Richard Fisher, Salisbury; and William Bruerton, Paington, Devon, of St. George's Hospital; Alexander Fox, Stoke Newington; Robert Walter Ceely, Poplar; and Septimus Evans, Devonport, of the London Hospital; Samuel John Truman, Nottingham; William Percival Magor Boyle, Penryn, Cornwall; and Arthur Horatio Morrill, Richmond, Surrey, of Guy's Hospital; Henry Bland, L.S.A., Bradford, Yorkshire; and Daniel King, L.S.A., Stretton, Cornwall, of King's College; Charles Henry Hines, Sunderland, of University College; George Wilks, Ashford, Kent, of St. Bartholomew's Hospital; John James Fraser, Manchester; and William Frederic Taylor, M.D., Queen's University, Kingston, Canada. Out of one hundred candidates who last week underwent their examinations, only eight failed to acquit themselves to the satisfaction of the Court of Examiners, and were consequently referred to their studies for a further period of six months.

**UNIVERSITY OF EDINBURGH.**—The annual meeting of the University of Edinburgh for conferring degrees in divinity, literature, and science and arts took place last Wednesday in the hall of the General Assembly, Sir David Brewster, K.H., Principal and Vice-Chancellor, presided, and there was a large attendance of the heads of the University, of the students, and of the public. The degree of D.D. was conferred on the Rev. Thomas Smith, editor of *The Library of Puritan Divines*, and on the Rev. Maxwell Nicholson, Tron Church, Edinburgh. It was also intended to confer the same degree on the Rev. G. Walker, minister of Kinnell, the Rev. David Pitcairn, author of several popular religious works, and on the Rev. Joseph Mullins, of the London Missionary Society, author of *The Religious Aspects of Hindu Philosophy*, but these gentlemen were unable to be present. The degree of LL.D. was conferred on Mr. James H. Stirling, "whose masterly analysis of the *Secret of Hegel* had been welcomed in many quarters as a most valuable addition to the literature of metaphysics," and the degree of Doctor of Science was bestowed on Mr. John Affleck, M.A., of Glasgow; Mr. H. A. Nicholson, B.S., of Edinburgh; and the Rev. Robert Jardine, Master of Arts and Bachelor of Divinity of Queen's College, Kingston, Canada. Nine young gentlemen were presented for the degree of B.D., one for LL.B., and three for Bachelor of Science. Seventy students had passed for the degree of M.A., of whom nine had taken honours. This was the largest number that had yet passed on any occasion, but some of those entitled now to receive the degree proposed to hold back in order to take the degree with honours next year. In the course of the year fifteen students had taken certificates of proficiency in classical literature, sixty-three in mental philosophy, and fifty-seven in mathematics. The address of the occasion was delivered by Professor Sellar, who spoke of the four latest rectorial addresses delivered in the Scottish Universities, and especially remarked Mr. Mill's address that the culture which it recommended was the equalized development of the faculties and intellectual sympathies through literature, science, and philosophy. This was, he said, the aim of the Scottish Universities, which were remarkable for the breadth of education imparted, and for deriving much of their very best materials from classes who, in other countries, would be debarred by the *res angusti domi* from thinking of a University education.

**GLASGOW UNIVERSITY COUNCIL.**—At a meeting of the Glasgow University Council, held last Wednesday—the Rev. Principal Barclay presiding—an excerpt from the minutes of a meeting of the University Court was read, from which it appeared that that Court had resolved to petition both Houses of Parliament to the effect that the four Universities of Scotland should have the privilege conferred on them of returning at least two members to the House of Commons—one to be chosen by the General Councils of St. Andrew's and Edinburgh, and one by the General Councils of Glasgow and Aberdeen. Mr. J. A. Campbell reported that the subscriptions on behalf of the new University buildings had amounted during the last half-year to £7265, bringing up the total sum subscribed at this date to £89,715.

**SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.**—(Established 1788; Incorporated by Royal Charter 1864).—Election of officers and directors at the annual general meeting, April 24, 1867:—President: George Burrows, M.D. Vice-presidents: Everard A. Brande, Esq.; Peter Mere Latham, M.D.; John Bacot, Esq.; John Miles, Esq.; Cæsar H. Hawkins, Esq., F.R.S.; James Paget, Esq., F.R.S.; Charles Hawkins, Esq.; Thomas Hammerton, Esq.; Sir Charles Locock, Bart, M.D., F.R.S.; John Probert, Esq.; Henry Alfred Pitman, M.D.; John Clarke, M.D. Treasurers: James Thomas Ware, Esq.; G. Hamilton Roe, M.D. (acting); Richard Strong Eyles, Esq. Directors: John Love, Esq.; H. W. Fuller, M.D.; John Adams, Esq.; Robert Druiitt, M.R.C.P.L.; J. C. Forster, Esq.; Edward Tegart, Esq.; John Scott, Esq.; Henry Lee, Esq.; C. Collambell, Esq.; Richard Quain, M.D.; George Johnson, M.D.; C. F. Du Pasquier, Esq.; E. U. Berry, Esq.; Samuel Solly, Esq.; John Morgan, Esq.; Robert Barnes, M.D.; George Budd, M.D.; William Bowman, Esq.; Prescott G. Hewitt, Esq.; W. Tiffin Iliff, M.D.; Richard Partridge, Esq.; G. Owen Rees, M.D.; Francis Sibson, M.D.; Edward Newton, Esq. The following members were elected trustees, to act with James Thomas Ware, Esq., viz.—George Burrows, M.D., the president, in the room of the late Thomas Arthur Stone, Esq., the former president; G. Hamilton Roe, M.D., in the room of the late Alex. John Sutherland, M.D.; and Richard Quain, M.D., in the room of Charles Hawkins, Esq., resigned.

**MEDICAL APPOINTMENTS.**

MAY, Joseph, L.A.D., L.R.C.P.E., L.F.P.S.G.L., M.D., has been appointed Medical Officer and Public Vaccinator for the Rathfriland Dispensary District, Newry Union, vice Samuel Swan, L.A.D., L.R.C.S.E., deceased.

SMITH, H. F., M.D., Staff Surgeon, having completed twenty years' full-pay service, to be Staff Surgeon Major. The restoration to full-pay of Staff Assistant Surgeon C. J. Davenport, M.D., has been cancelled, with a view to his continuing upon half-pay for a further period of twelve months.

ALLNUTT, J. E., M.R.C.S.E., has been reappointed Medical Officer for the Landport District of the Portsea Island Union.

DAVIES, A., M.D., has been elected Physician to the West Kent General Hospital, Maidstone, vice Dr. Woodfall, deceased.

DAVY, R., M.R.C.S., has been elected Surgeon to the St. Marylebone General Dispensary.

HARRISON, C., M.D., has been elected Honorary Surgeon to the Lincoln General Dispensary, vice J. Hewson, F.R.C.S., deceased.

HYDE, G. E., L.R.C.P.L., has been appointed Surgeon to the County Gaol, Worcester, vice E. Lowe, M.R.C.S.E., deceased.

NORRISH, J., M.R.C.S.E., has been appointed Resident Medical Officer to the Islington and North London Provident Dispensary, vice Dr. M'Dermott, resigned.

RICHARDSON, B. W., M.A., M.D., F.R.C.P., has been appointed Physician to the London Infirmary for Epilepsy and Paralysis.

SMITH, J., M.R.C.S.E., has been appointed a Surgeon for the Aston District of the Union Provident Sick Society, Birmingham.

SOMERVILLE, W., M.D., has been appointed Medical Officer for the Muncaster District of the Bootle Union, Cumberland.

STONE, J. P., M.R.C.S.E., has been appointed Medical Officer for the Dittisham District of the Totnes Union, Devon.

TAYLOR, T., M.R.C.S.E., has been appointed Medical Officer for the Workhouse, Baintree Union, Essex, vice C. Dixon, M.R.C.S.E., resigned.

TAYLOR, T. T., M.R.C.S.E., has been appointed Medical Officer for District No. 3 of the Cricklade and Wootton Bassett Union, vice Thomas Taylor, M.R.C.S.E., resigned.

TRUBSHAW, A., M.R.C.S.E., has been appointed Junior House Surgeon to the Southern Hospital, Liverpool, vice J. H. Evans, M.R.C.S.E., resigned, on being appointed Hon. Curator to the Liverpool-Royal Infirmary School of Medicine.

TURNER, R. S., M.A., L.R.C.S.Ed., has been appointed Resident Assistant to the Extra Physicians at the Royal Hospital for Sick Children, Edinburgh.

TYLEY, R. P., M.D., M.R.C.S., has been appointed Medical Officer to the Wedmore District of the Axbridge Union.

WALKER, H., M.D., has been appointed Medical Officer for District No. 4 of the Beverly Union, Yorkshire, vice T. Sandwith, M.D., deceased.

WARRILLOW, L., M.R.C.S.E., has been appointed Medical Officer for District No. 7 of the Parish of Birmingham.

WATHEE, J. H., L.R.C.P.Ed., has been appointed Assistant House Surgeon to the General Hospital, Bristol, vice J. Wells, M.R.C.S.E., resigned.

WELCH, T. D., M.D., has been appointed Physician to the Kent and Canterbury Hospital, Canterbury.

WILCOX, R. W., M.R.C.S.E., has been appointed Medical Officer for District No. 5 of the Aylesbury Union, Bucks.

WILSON, G., L.R.C.P.Ed., has been appointed Medical Officer for the Islandshire District of the Berwick-upon-Tweed Union.

WITTEY, E. W., M.R.C.S.E., has been appointed Medical Officer for the Lullington District of the Burton-upon-Trent Union, vice W. Anderson, M.D., resigned.

**NOTICES TO CORRESPONDENTS.**

*Dr. Morton.*—The candidate must be registered as the holder of a Medical and Surgical Qualification.

*F.R.C.S.*—The discrepancy is obvious, though it might have led to serious results. You were perfectly justified in treating the case as mentioned.

*Dr. P.*—"The British Pharmacopœia" is announced to be ready for delivery on May 1.

*Medicus.*—We have been yet unable to verify the fact stated in the note, as there is no provision for obtaining any Parliamentary Paper from the Agents who profess to keep them in Dublin. We expect the returns from London, and will give them our best attention.

The following communications are unavoidably postponed:—Dr. John Geo. Thornley on "Lodgment of a Coin in the Oesophagus;" Dr. John Hawthorne's "Case of Successful Operation for Strangulated Inguinal Hernia;" "Sanitary Condition of the Federal Army;" Dr. Asbe's letter "On Preliminary Professional Education;" Dr. Patterson's Communication "On Parotitis."

*Dr. Kidd, Ballymena.*—We cannot ascertain that there is any foundation for the statement to which you refer. We shall feel obliged if you will let us know in what part of the journal it appeared.

*Dr. Brown, Belfast.*—If correspondent will look again at our review of the pamphlet in question, he will find that our opinion of it was by no means commendatory—quite the reverse; and much on the same grounds as those set forward in his letter. As to outstying the writer of it "Dr.," we can only say that we adopted the common, but inexact, style of speaking of practitioners generally; and our correspondent must know that many "homopathists" are quite as much entitled to this title as the best men in our Profession. It certainly never occurred to us that the writer of the pamphlet was not a *legally qualified* quack; and we think the question as to the title is that of least importance in this matter, seeing that the pamphleteer can, if he will, become a German "Doctor in Philosophy" on easy terms, and so place his right beyond dispute. The real question is—did THE MEDICAL PRESS AND CIRCULAR, which has always opposed quackery, give a favourable review of a quack pamphlet? To this we decidedly say *no*. We reviewed it only to expose its real nature; and that in the shortest and most unmistakable terms.

THE RECENT POOR-LAW INQUIRY AT THE LIMERICK UNION WORKHOUSE.—We publish, in another part of our issue, the letter of the Poor-Law Commissioners, conveying their verdict with respect to the charges against Dr. O'Sullivan. The reply of Dr O'Sullivan and the proceedings of the Board of Guardians with reference to it, came under our notice too late for analysis in this number. We hope to enter on the question next week.

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

- AICKIN.—On the 15th ult., the wife of W. Aickin, M.D., of Belfast, of a son.
- ARNOLD.—On the 22nd ult., at Fountainville-terrace, Belfast, the wife of Dr. Wilberforce Arnold, L.K.Q.C.P.I., of a son.
- BOWER.—On the 17th ult., at Clarence Villas, Windsor, the wife of Edmund Bower, M.D., of a son.
- CÆSAR.—On the 18th ult., at Downton, the wife of R. T. Cæsar, M.R.C.S.E., &c., of a son.
- COWAN.—On the 27th March, at the Green Mountain Hospital, Ascension, the wife of M. W. Cowan, M.D., Surgeon, R.N., of a son.
- DIAMOND.—On the 16th ult., at Dudley Villa, Efra-road, Brixton, the wife of W. H. Diamond, M.R.C.P.Ed., of a daughter.
- DIVER.—On the 20th ult., at Reading, the wife of E. Diver, M.D., of a daughter.
- HASTINGS.—On the 22nd ult., at Queen Anne-street, the wife of Dr. C. Hastings, of a daughter.
- LILLIES.—On the 7th ult., at Chudleigh, the wife of G. W. Lillies, M.D., of a daughter.
- MAUNSELL.—On the 10th ult., at Upper Norwood, the wife of Dr. S. E. Maunsell, 97th Regiment, of a daughter.
- MILLER.—On the 20th ult., at St. Vincent-street, Glasgow, the wife of Hugh Miller, M.D., of a daughter.
- MURPHY.—On the 9th ult., at Dingle, Co. Kerry, the wife of Dr. Murphy, of a son.
- REED.—On the 15th ult., at Hertford-street, May-fair, the wife of Dr. Reed, prematurely of a daughter.
- SAUNDERS.—On the 16th ult., at Queen-street, Cheapside, the wife of W. S. Saunders, M.D., of a son, still-born.
- SHARMAN.—On the 13th ult., at Knight's-hill, Lower Norwood, the wife of J. Sharman, M.R.C.S.E., of a son.
- THOMPSON.—On the 24th ult., at Droxford, Hants, the wife of James Thompson, M.B., M.K.Q.C.P.I., L.R.C.S., late Army Medical Staff, of a son, still-born.
- WILLIAMS.—On the 14th ult., at Kensington, the wife of Dr. L. Williams, of a son.

### MARRIAGES.

- EAMES—CARR.—On the 9th ult., at St. Stephen's, Westbourne-park, Henry Eames, M.B., to Jane Catherine, daughter of the late David Carr, Esq.
- GRIFFITH—STARBUCK.—On the 11th ult., at Steynton, Dr. Griffith, Surgeon in charge of Troops, Milford Haven, to Mary, eldest daughter of A. B. Starbuck, Esq., J.P., Milford Haven.
- HERBERT—GALWEY.—On the 23rd ult., at St. Stephen's Church, Dublin, Henry Carden Herbert, M.D., F.R.C.S.I., 85th Light Infantry, to Isabella Miranda, daughter of Edward Galwey, Esq., of Lower Baggot-street, Barrister-at-law.—Cards not sent.
- NEATE—BRADFORD.—On the 24th ult., at Farcet, Hants, Chas. W. P. Neate, Esq., Surgeon, of Yaxley, near Peterborough, to Harriette, only daughter of Samuel Bradford, Esq., of Park House, Farcet.

### DEATHS.

- BURDETT.—On the 11th ult., W. Burdett, M.R.C.S.E., of Tinwell, formerly of Stamford, Consulting Surgeon to the Stamford and Rutland Infirmary.
- COLLINS.—On the 18th March, at Macroom, Co. Cork, James Collins, M.D., late of Liverpool, aged 74.
- DARBY.—On the 10th March, at Maddox-street, W. Darby, late Superintending Surgeon Cawnpore Division, Bengal Service, aged 76.
- DOLMAN.—On the 15th March, J. D. Dolman, M.D., of Souldern House, Banbury, aged 56.
- DYSON.—On the 16th March, J. Dyson, Surgeon, of Hornley, near Huddersfield.
- EVANS.—On the 3rd March, W. Evans, Surgeon, of Queen-street, Devonport, aged 72.
- FAIRMEAD.—On the 12th March, J. Fairmead, L.S.A.L., of London-road, Enfield, aged 77.
- FLEMING.—On the 2nd ult., J. Fleming, M.R.C.S.E., of Orton, Westmoreland, aged 27.
- JONES.—On the 20th of Feb., at Gellyglyd, Llanegwad, Carmarthen, South Wales, J. Jones, M.D., aged 76.
- KIRKPATRICK.—On the 23rd, at Torquay, Devon, T. Kirkpatrick, M.D., of Larne, late Insp National Agricultural Schools, aged 62.
- O'SHEA.—On the 8th ult., at Kenmare, O'Shea, Medical Student, Queen's College, Galway.
- PRICKETT.—On the 7th March, G. B. Prickett, M.D., of Bampton, Oxfordshire, aged 38.

## PURCHASERS OF SADDLERY AND HARNESS ARE RESPECTFULLY INVITED TO INSPECT

J. HINKSON'S

Large Assortment of Improved PRIZE, SIDE and HUNTING SADDLES, DOUBLE and SINGLE HARNESS, Plated on German Silver, and other kinds of Mountings; with everything in the Trade at very Moderate Prices.

SADDLER TO THE LORD LEUTENANT.

76, DAME-STREET.

Old Saddles and Harness taken in exchange.

PLEASE NOTICE REDUCTION IN PRICE.—BEST QUALITY ONLY.

Great Saving in the Purchase of New Medical GLASS BOTTLES and PHIALS of the best Manufacture, at the NORTH LONDON GLASS BOTTLE WORKS, I. ISAACS and COMPANY, Proprietors.—London Warehouses, 25 and 24, Francis-street, Tottenham-court-road, W.C.

6 and 8 oz., any shape, plain or graduated,	} Clear blue tinted	{ 8s. 6d. per gross.
3 and 4 oz. ditto		
½ oz. Moulded Phials	} Of a very superior quality	{ 4 6 " "
1 oz. ditto		
1½ oz. ditto		
2 oz. ditto		

The Improved FLINT GLASS BOTTLES, with Lip, a very superior article, in 6 Gross Packages, assorted to suit the convenience of purchasers, at the following reduced prices:—

3 and 4 oz. - 9s. 6d. per gross. | 10 and 12 oz. - 16s. 0d. per gross.

6 and 8 oz. - 10s. 6d. | 16 " - 19s. 0d.

Measures, Pill Boxes and Corks, and all Sundries, supplied "order.

A remittance not required till the goods are received. Packages free. Immediate attention to Country Orders. Goods delivered free within 7 miles. Post-office Orders payable to I. ISAACS & CO., at the Post-office, Tottenham-court-road.—Bankers, London and Westminster Bank (Bloomsbury Branch).

Established upwards of 70 years.

NOTICE.—BEST QUALITY ONLY.

Further Reduction in the Prices of New MEDICAL GLASS BOTTLES and PHIALS, at the ISLINGTON GLASS BOTTLE WORKS, Islington-place, Park-road, London Warehouse, 19, Bread-street-hill, Upper Thames-street, City, E.C., and 2, Upper Copenhagen-street, Barnsbury-road Islington. E. & H. HARRIS and CO., Proprietors.

BEST QUALITY ONLY.		per gross.
6 and 8 oz., any shape, plain or graduated,	} Clear blue tinted	{ 8s. 6d.
3 and 4 oz. ditto ditto		
½ oz. White Moulded Phials	} Of a very superior quality.	{ 4 6 " "
1 oz. ditto		
1½ oz. ditto		
2 oz. ditto		

Measures, Pill Boxes and Corks, and all sundries, supplied to order.

The Improved FLINT GLASS BOTTLES, with Lip, a very superior article, in 6 Gross Crates, assorted to suit the convenience of purchasers, at the following reduced prices:—

3 and 4 oz. ... 9s 6d per gross. | 10 and 12 oz. ... 16s 0d per gross

6 and 8 oz. ... 10 6 " | 16 oz. ... 19 0 "

Immediate attention to country orders. No remittance required until the goods are received. Packages free. Goods delivered free within seven miles. Post-office orders payable to E. and H. HARRIS and CO., at the Chief Office, London.—Bankers, Alliance Bank. Established upwards of 80 years.

## W. H. BAILEY & SON,

413, OXFORD-ST., LONDON, Having received a PRIZE MEDAL at the International Exhibition, 1862, can with confidence recommend their Improved Instruments for SPINAL CURVATURE, which effect a cure in all recent cases, and give relief in the more advanced stages. IMPROVED INSTRUMENTS for all kinds of Deformities. Superior light TRUSSES for Hernia. RAILWAY URINALS. ELASTIC

STOCKINGS, KNEE-CAPS, &c.

Catalogues sent free by post on application.

## Cooper's Sinapine TISSUE, or MUSTARD PAPER,

the New Mustard Poultice recommended by the Faculty, free from Cantharidine.

A. Cooper begs to inform the Medical Profession that they can now be supplied with his Sinapine Tissue in packets at 3s. 6d. and 6s. 6d. (equal to six and twelve 1s. packets), free by post on receipt of stamps. A sheet of Medical Testimonials accompany each packet. Sole Inventor and Manufacturer, A. COOPER, Pharmaceutical and Dispensing Chemist, 18, Abingdon-terrace, Pembroke-square, Kensington, London.

## PARALYSIS: CASES ILLUSTRATIVE OF A NEW METHOD OF TREATING IT BY THE APPLICATION OF COLD OR HEAT ALONG THE SPINE.

By JOHN CHAPMAN, M.D., M.R.C.P.,

PHYSICIAN TO THE FARRINGTON GENERAL DISPENSARY.

(Continued from p. 413.)

THE following interesting case illustrates the propagation of a morbid influence from the medulla oblongata upwards, producing disorder of the cerebrum, and downwards producing paraplegia, and, at the same time, proves the remarkable power of the spinal ice-bag as a remedial agent.

3.—*Case of Paralysis of the lower extremities associated with partial blindness, as well as temporary and partial imbecility.*

H. R., male, aged two years and eleven months, who suffered when five months old from violent and prolonged convulsions, with congestion of the brain, and who was then treated by me successfully by means of ice, was brought to me January 2, 1866, on account of staggering, and so much weakness of the lower extremities, that when he attempted to walk he stumbled, and frequently sank down; his mind was so impaired that it was difficult to elicit from him any answers to questions, or to excite in him any interest in outward objects; he could not see distinctly, and was unable to see or pick up coins if thrown down on the ground before him; the eyes seemed as if almost fixed in the orbits, and the pupils were remarkably immobile. He was also troubled with profuse dribbling of saliva. I ordered a powder consisting of two grains of mercury with chalk, and five grains of compound rhubarb powder to be taken every other night, or less frequently if the bowels should become freely open; also, a saline mixture, to be taken three times a-day, containing a grain of iodide of potassium in each dose. At the same time, I prescribed the application of ice in each cell of the spinal ice-bag, during fifteen minutes three times a-day.

Jan. 18th.—One of the powders was given about every third night, and the ice, owing to the resistance of the child to it, was applied only once in each twenty-four hours, viz.—when he was asleep; his eyes, however, look much more natural, and his mother says he moves them about now; he distinguishes objects better, and is more lively and intelligent than when I last saw him; I then requested the ice to be applied along the lower half of the spine during thirty minutes each night.

24th.—Intelligence and visual power have improved, but the paralysis of the lower extremities has increased: he is unable to walk at all, and during the last few days has scarcely put his feet to the ground. To give five grains of compound scammony powder occasionally, if the bowels should be constipated; to continue the mixture as before; to make a jacket with a linen pouch on the inner side of the back of it, corresponding to the length of the spine, and having filled each cell of the spinal ice-bag, and placed it within the pouch, to put on the jacket thus prepared three times a-day, during thirty minutes. Also, to give the child a warm bath at 100 Fahrenheit each night.

February 1st.—The ice-bag jacket has not only been well borne, but its use has been looked forward to, and welcomed by the child; he can now walk a considerable distance, the length of two rooms for instance, if led by the hand, and is generally improved and very lively; the pupils move freely under the influence of light; there is, however, slight paralysis of the left external rectus. The treatment last ordered to be continued.

2nd.—Has again become heavy and dull, and was sick this morning. To let the evening application of ice be restricted to the lower half of the spine, and continued during forty-five minutes.

10th.—Is much better in all respects; can walk without being led, and very easily when led by the hand; vision

believed to be quite natural; the squinting has ceased; the patient sleeps well, and is in capital spirits; appetite good; bowels open daily without the aid of medicine. He has, however, a little cough, and is slightly hoarse. To omit the ice in the middle of the day, and to continue the warm bath and mixture as before.

24th.—Head quite well; vision continues perfect; patient walks freely alone, but not quite steadily; he has a slight eruption on the face, and flushes frequently. To restrict the spinal ice-bag to the lower half of the spine, and to continue its use three quarters of an hour each morning as well as at night.

March 7th.—The child is thoroughly lively and intelligent; has no ailment except that he is troubled with a dribbling of saliva, and walks with hesitation; he drags the left foot slightly, and seemingly raises the leg somewhat spasmodically. To omit the mixture; to use the aperient powder only when necessary, and to apply ice along the upper half of the spine each morning and afternoon, and along the whole spine each night during thirty minutes.

Three weeks after the last date every symptom from which the child had suffered, except the dribbling of saliva, had completely disappeared. By persistence in the use of the ice, as last ordered, this trouble was soon also overcome, and the child has long continued well in all respects.

In considering the history of this case there are two or three points which deserve special attention:—1st. The resistance which the child offered to the application of the ice, and the way in which that resistance was overcome. 2nd. The changes made from time to time in respect to the parts of the spine to which the ice was applied; and, 3rdly, the action of the ice on the cerebral circulation, and especially in improving the visual power.

From considerable experience I can state confidently, as a general rule, that when in the treatment of any disease ice operates beneficially, its application, far from being painful, is positively agreeable, and generally exerts a peculiarly calming and soothing, as well as tonic, influence. The experience of the present case is no exception to the truth of this statement. The opposition made by the child in the first instance to the application of the spine-bag was merely due, I presume, to fright at an unfamiliar procedure. When the ice was applied at the time the child was asleep he evinced no discomfort, it did not wake him as it would have done had it been distressing; and as stated, when it was applied within the pouch of a jacket, instead of occasioning any discomfort its use was "looked forward to with pleasure and welcomed by the child." I may here observe that in applying ice to children, the use of the ice-bag jacket as above described is invaluable and often indispensable. The little patients if not completely prostrate are so restless and active that the use of the jacket is the only expedient I can think of by which the spine-bag can be retained exactly in its place, without entailing upon the mother or nurse the necessity of incessant watchfulness; for in adopting this treatment the retention of the ice over the part indicated is a *sine qua non*: if the ice is not over the spine but over the side of the chest it will not be doing good but harm; and if, when it ought to be applied to one region of the spine, the lower third for example, it is actually applied to another, the upper third for example, it may produce effects precisely opposite to those intended.

When the patient in question was first brought to me, I came to the conclusion that the symptoms of cerebral disease which, as I found, were associated with coolness of the forehead, were due to abnormally excessive excitability of the upper portion of the spinal cord, including the medulla oblongata, and collateral ganglia of the sympathetic. This conclusion was based mainly on two considerations: first, that there was dribbling of saliva, indicative of undue excitement of the medulla oblongata; and, second, there was coolness of the forehead, indicative of the vigorous action of the sympathetic ganglia in question, which resulted in keeping the arteries of the cerebral lobes fairly contracted, notwithstanding that the base of the brain was in a state of considerable irritation, which being propagated

down the cord produced the paralysis in question. Hence I decided to apply ice along the upper as well as the lower portion of the spine. It was thus applied daily during eighteen days. At the end of that time the symptoms of cerebral disorder were considerably lessened, but the power of the legs had not perceptibly increased; therefore, with a view of so acting as to combat directly the most pressing symptom, I ordered the ice to be restricted to the lower half of the spine. But although the intelligence and visual power continued to improve, the paralysis of the lower extremities instead of lessening grew worse. In seeking to divine the cause of the latter effect, I came to the conclusion that inasmuch as the direct influence of the cold was probably exerted as high up as the highest dorsal vertebra it exercised a slight dilating influence on the cerebral arteries, while, at the same time, the ice having been withdrawn from the cervical region, the medulla oblongata and other parts at the base of the brain became even more hyperæmic than before the treatment was begun. Hence, as in the first instance, ice was again applied in each cell of the spine-bag, and was then continued thirty minutes, three times a-day. Afterwards, on account of a little hoarseness and cough, I omitted the ice at noon, and at a later date restricted it, when applied in the evening, to the lower half of the spine, because, *cæteris paribus*, when thus applied it is most conducive to sleep.

At a still later date, in consequence of a slight eruption and frequent flushing, I ceased the application of cold to the upper part of the back in the morning as well as in the evening. These symptoms having disappeared (and it is worthy of observation that while the cold was withdrawn from the upper part of the spine, the power of walking was impaired again) I ordered the ice to be again applied each morning and afternoon along the upper half of the spine, and along the whole spine each night. The satisfactory results seem to show very clearly that the real source of the malady was hyperæmia of the upper part of what Dr. Marshall Hall calls "the true spinal cord," and of the collateral sympathetic ganglia as I inferred in the first instance.

The last point in this case to which I shall advert is the effects of the treatment described on the eye. It will be remembered that the child, when brought to me, was partially blind, the eyes seeming to be fixed in the orbits, and the pupils being remarkably immobile. Now, this condition of fixedness of the eyes was presumably due to a slightly spasmodic condition of the ocular muscles—a condition, which, itself, would originate in hyperæmia of the base of the brain, and the persistence of which would be favoured by a like vascular state of the sympathetic ganglia controlling the arteries of the orbits, as well as those of the cerebral lobes and eye itself; for a slight contraction of those arteries, thus diminishing the supply of blood to the muscles in question, would be favourable to the production of spasm. Moreover, the immobility of the pupil, though it might be caused either by disorder of the nervous centre presiding over its contraction, or by disorder of the cilio-spinal region, whence originate the nerves affecting the dilatation of the pupils, was, in all probability, produced by a congested condition of both centres simultaneously. If so, the iris would be maintained by the antagonistic influence of the two sluggish forces in the immobile state, neither extremely contracted, nor extremely dilated, in which it was found. These views respecting the cause of the condition of the ocular muscles and of the iris are confirmed by the results of treatment in respect to vision itself. Of course it is probable that if that condition were due to the cause alleged, that same cause would operate in producing abnormal contraction of the retinal arteries, and consequently in diminishing the nutriment of the retina, or, in other words, in establishing partial amaurosis, which I feel confident was the actual state of the eyes in this case. This disease, when due to a proximate cause of the kind just explained, would, of course, be most likely to be relieved or cured by the application of ice along the upper third of the spine; and as the sight in this case was completely restored by this method, the result goes far to prove that the diagnosis was

correct. It would be scarcely possible to exaggerate the importance of the therapeutical discovery which the facts of this case tend to establish, and which, I am happy to say, has been proved to be indubitable by my experience in several other cases, in which vision has been wonderfully improved in a similar manner, as well as by the experience of Mr. Ernest Hart, who, kindly acting on my suggestion, has verified the great curative power of cold and heat applied along the spine in the treatment of eye affections. Of course these facts being established, the power of exciting a controlling influence over the internal carotid, and therefore over the cerebral circulation, by modifying the temperature of the spinal region, is proved to be now within reach of the physician.

#### 4.—Case of Tetanoid Paralysis of the four extremities.

A boy, aged two years and four months, was brought to me, April 10, 1866, suffering from rigidity and immobility of the extremities. The arms were stiff, though still partially movable; the thumbs were forcibly bent within the palms of the hands, and the fingers were drawn over them and fixed in a state of semi-flexion. The legs were extended and rigid, the feet being also firmly fixed as in *talipes equinus*. All four limbs were swollen; the dorsum of each foot so much so as to make the skin tense and glistening. There were also slight ecchymoses on the feet. The sensibility was extremely heightened: touching the hands or feet caused the child at once to scream; in fact he screamed if he saw his feet approached. He also suffered from diarrhoea.

I ordered the application of ice by means of two ten inch spinal ice-bags—one being placed along the spine, and the other across the occiput, extending from ear to ear, thus forming an ice-pillow. The applications were continued about two hours, and were repeated in the same manner, four times each day, during the early part of the treatment. Afterwards the applications were less frequent. The child was immediately soothed, slept well the following nights, and rapidly became generally calmer and better. On the 12th the fingers had become more supple; the extremities could be freely handled without causing pain, and the diarrhoea had ceased. By the 25th he could walk the length of a room, and by the 2nd of May he was able to walk with perfect ease, and, indeed, had completely recovered, except that there was a slight eversion of the left foot, which has since disappeared.

The severe inflammatory condition of the spinal cord, characteristic of this case, is one which, so far as I know, is incapable of subjugation by any of the ordinary methods of treatment hitherto practiced. I may observe here that my experience in several cases has enabled me to ascertain precisely what is the significance of that remarkable phenomenon often associated with disease of the spinal cord, viz.—a feeling of constriction, or of a tight band round some part of the trunk of the body. It consists of slight spasm of those muscular fibres related to the spinal nerves, which happen to originate in that part of the cord which is peculiarly hyperæmic, and which, therefore, is transmitting from a limited area of nerve-cells a superabundance of motor-impulses to the muscular fibres in question. By the application of ice over the affected part of the spinal cord, the symptom is made to subside, while, on the other hand, it may, in some cases, be induced by the application of heat to the spine. It has occurred temporarily on several occasions in patients not paralytic, but who were being treated by me on account of diseases which necessitated the use of heat. This case is particularly instructive as an illustration of several important doctrines forming part of the pathological views which I advocate. And first, as to the essential nature of inflammation, the proximate cause of which I conceive to be, as stated in the introduction to my work on *Diarrhoea and Cholera*, a vehemently intense activity of the whole or of some part of the spinal cord. Believing, as I do, that the elements of every tissue in the body are under the influence of this great centre, depend upon it for their electro-chemical force, by which they select from the blood their appropriate nutri-

ment, and may thus become more or less vitally active, accordingly as they receive a greater or less amount of stimulus from the cord, I regard the swelling and allied symptoms which took place in this child, as an example of preternatural nutrition due to excessive energy of the intensely excited spinal cord. During about a month previously to the date when the child was brought to me, he had seemed to become generally and rapidly stout; so rapidly, indeed, that the nurse felt concerned in observing this change, although she had no idea that it was a morbid one. She particularly noted that not only were the limbs increased in size, but that the child had acquired a "double chin." The temperature of the limbs, as I have already stated, was abnormally high. As, owing to the influence of the ice along the spine, the extreme spinal hyperæmia became gradually subdued, the general swelling of the little patient steadily subsided. By the 14th April, I was enabled to enter in my note-book: "he looks more natural; less puffy and swollen generally;" and, by the 18th, I was enabled to say, "the general swelling has so much subsided, that he looks considerably thinner, and the expression of his face is proportionably improved." That this symptom, swelling, was due to a hyperæmic state of the cord, bordering on inflammation, seems to me, apart from the theory I hold, fairly demonstrable by two facts,—First, there was intense hyperæsthesia all over the body, a phenomenon ascribed, I believe, by every one except Dr. Bland Radcliffe and his disciples, to hyperæmia of the spinal cord; and, second, the application of ice over the cord, a procedure calculated to subdue hyperæmia of that organ, if it existed, did actually subdue the general swelling from which the little patient suffered.

Another important symptom in this case was diarrhoea. The child had, on several occasions, suffered from this malady, which in each case was induced by dental irritation, which, as is generally conceded, is a fruitful source of extreme cerebro-spinal excitability. Now, on each of these occasions the child had been rapidly soothed, and the diarrhoea completely stopped by means of the spinal ice-bag. During several days before I saw him, when he was suffering from what I have called tetanoid paralysis, he had been troubled with diarrhoea, a disease which, as I have endeavoured to demonstrate in my work already mentioned, can never supervene, whatever may be its ultimate cause, without the intervention of an excessively hyperæmic state of those segments of the spinal cord immediately related to the bowels. That this state existed in the present case, I have shown by evidence just adduced, and that it was in this case the proximate cause of the diarrhoea may be fairly inferred from the fact that the abolition of the hyperæmia in question resulted in the speedy cure of the diarrhoea.

I will close these comments by adverting to the interesting and very important evidence which the case affords, of the great power which we possess in the form of the spinal ice-bag, of subduing that intolerably intense sensitiveness often observable in patients suffering from what are called diseases of the nervous system, and which was a remarkably prominent feature in this case. The child when first seen was so fearful of being touched, particularly on the feet, that he screamed if he saw them approached. The first night after the ice was applied he was greatly soothed and slept well, the excessive sensitiveness steadily declined, and at the end of a week, after the treatment began, he could bear the soles of his feet to be freely pressed upon without suffering pain.

The efficacy of this method of treating paraplegia is strikingly attested by the statements contained in the following letter addressed to me by a disinterested witness who was previously unknown to me:—

5.—*Case of Paraplegia, involving loss of sensibility as well as of motor power.*

"Guestling Lodge, near Hastings, Sussex.

9th January, 1864.

"Sir,—Having given some attention to the subject of paralysis during twenty years' service in India, and lament-

ing, as we all must do, our comparative want of success in its alleviation, I was much interested by your paper in *The Medical Times* of October 17th, 1863.

"I am not in practice, being at home only on furlough, but I heard of a girl in the neighbourhood who was bedridden from paraplegia, and I was requested by her mother to visit her, although the case had been pronounced hopeless.

"I found her incapable of turning in bed, all motion and sensation absent from a little above the knees downwards.

"There was great tenderness of the spine in the lower cervical and in the dorsal region.

"General health was good, menstruation natural.

"I applied ice to the spine daily with frictions, and in ten days sensation commenced in the feet, followed by slight motion. Steady improvement has taken place. She has risen from her bed, and on Christmas day I had the satisfaction of meeting her walking in the village street of Orr, in which she resides, at No. 3, Caroline-place. I intend, if possible, getting her case from the Infirmary in Hastings, where she was for some time under treatment, and I shall be happy to have some conversation with you upon the subject, at some future date, before I return to India.—  
Yours truly,

F. BROUGHTON F.R.C.S.  
Surgeon-Major, Bombay Army."

I may add here that Dr. Russell Reynolds mentioned to me a case of complete paraplegia in which a cure had been effected by the spinal ice-bag, and with a rapidity even more astonishing than that distinguishing the case just related.

(To be continued).

#### CASE OF SUCCESSFUL OPERATION FOR STRANGULATED INGUINAL HERNIA, WITH SOME UNUSUAL COMPLICATIONS.

By JOHN HAWTHORNE, M.D., L.R.C.S. Ed.

A. G., æt. 50, a fireman in our gas works, has suffered from right inguinal hernia for 20 years. On Sunday December 21, 1865, while moving about the house at mid-day, having on no truss at the time, he took a violent fit of coughing, which forced down through the right inguinal canal a much larger hernial protrusion than usual. He became sick and faintish, lay down until the faintness passed off, and then made ineffectual attempts to reduce the hernia. Violent and continuous vomiting set in about 2 P.M., severe and spasmodic pain, and difficult respiration. I was asked to see him about 2.30, and found him suffering from severe pain in the tumour, and over the lower part of the abdomen—swelling filling the right side of the scrotum, very tense, and evidently very tightly constructed. The scrotum was considerably ecchymosed from the free handling and efforts of the patient to reduce the hernia. Tried the taxis, but the tumour was become so painful that he could not bear it to be handled. Sent for a medical friend Dr. Rowan. We agreed to give him chloroform, as we had no means of giving him a warm bath, and the man was become so weak we could not think of reducing him further with antimony or tobacco enema. He was placed fully under the influence of chloroform, but we could not by any justifiable force succeed in reducing the hernia. When he awoke we told him the necessity of a further operation, and he at once consented. We got him placed on a table in a good light, and at his own request gave him the chloroform again. Shortly after the commencement of the inhalation, I observed the respiration cease, the chloroform was withdrawn, and cold water dashed over the face and chest, and the tongue drawn forward. After the interval of a few anxious seconds respiration again commenced, and the patient was restored to consciousness. The operation was then commenced without the further use of the ænæsthetic. The stricture was found at the external abdominal ring. The edge of the knife was pressed against it, without any sawing motion, and the stricture divided. Still the hernia could not be reduced, the incision

was slightly increased, the sac was not opened, and now the hernia passed up with the usual garguilement. The external wound was brought together by four points of interrupted suture, water-dressing, a compress and bandage were applied, the patient removed to bed, and a full opiate administered.

10 P.M.—Same night, patient felt better; pulse 110, weak; thirsty; tongue dry in centre; some tenderness over ascending colon; had two hours sleep; vomited once; gave him effervescent citrate of potash with two minims acid hydrocy. every four hours, and half grain doses of opium in the intervals of the draught.

January 1, 1866, 9 A.M.—Slept some during night; pulse 100, stronger; tongue very dry in centre; very thirsty; vomited once during the night; felt better, and more cheerful; had slight cough, and on stethoscopic examination detected double mitral murmur; no bronchial rales. Gave him a mixture of ammon. acet. æth. chlor. vin. ipecac. in mist. camph. every four hours, mustard to be applied over the front of the chest.

8 P.M.—Felt better, had a tolerable good day, no vomiting; pain in right side abating; tongue still dry in centre, thirst not so great; pulse 100. To continue the mixture, omit the opium.

2nd, 9 A.M.—Slept some in early part of night, towards morning cough became troublesome; at time of visit, cough constant, short, unable to get up any expectoration; face dusky; pulse 120; very weak, skin soft; respiration very hurried; tenderness extending over right side of abdomen, as high as seventh or eighth rib; diffuse inflammation of the cellular tissue had evidently set in. Ordered hot fomentation over abdomen for half an hour; a linseed meal poultice as hot as could be borne every four hours; to take a mixture of ammon. carb. decoct. senegæ. tinct. opii. camph. every second hour.

The mustard to be re-applied over the front of the chest for an hour; a tablespoonful of brandy every third hour; beef-tea to be given freely during the day, and ol. ricini ℥j. in the brandy at twelve o'clock.

8 P.M.—Breathing easy; cough not so troublesome, getting up some expectoration; bowels not acted on; pulse 110; looks a little better. Gave him an enema of ol. ricini and terebrinth. which acted freely on the bowels, and the patient experienced much relief. The mixture to be given regularly during the night; also the beef-tea and brandy.

3rd, 9 A.M.—Appearance much improved; breathing easier; cough not so troublesome; can expectorate easily; tongue still dry in centre; pulse 100; had several hours good sleep; some discharge of healthy pus from upper end of wound; ligatures withdrawn; lower half healed by first intention; tenderness of side greatly diminished; the mixture every fourth hour; beef-tea and brandy as before.

9 P.M.—Looks much worse; had a rigor during the evening; tenderness over side greatly increased; discharge of pus thin, sanious; sunken expression of face; pulse 130, very weak and intermitting; not able to expectorate; tongue very dry all over; lips and teeth covered with sordes; very restless, and apparently dying. The senega and ammon. mixture to be continued every second hour, with the addition of twenty minims of tinct. digital. to each dose; and every alternate hour, one scruple dose of the bi-sulphide of soda in water, washed down with one ounce of brandy, in hot water and sugar. Mustard to be applied to front and sides of chest for an hour, and, if necessary, to be repeated during the night.

4th, 9 A.M.—Greatly improved; had two hours sleep after 5 A.M.; breathing much easier; little expectoration, and coming up freely; cough easier; had some tea and bread for breakfast before I saw him; pulse 100, full and free from intermission; tongue still dry in centre, moist at edges and tip; wound discharged about two tablespoonfuls of healthy pus; soreness of side relieved, but tender on pressure. Patient feels better and more hopeful since operation; some appetite. Chicken soup and beef-tea, to be given freely; the bi-sulphide every fourth hour, washed down with the brandy as before; mixture to be continued,

8 P.M.—Better; pulse 92; cough better; urine passed freely; a tablespoonful of pus from wound; water-dressing; chlorodyne draught.

5th, 9 A.M.—Four hours sleep; cough not troublesome; expectoration easy; expression of face improved; pulse 84; tongue moist on sides and tip; lower two-thirds of wound healed. Beef-tea and arrow-root during the day; a tablespoonful of brandy every fourth hour; the mixture every sixth hour; half-an-ounce of castor oil at mid-day; omit bi-sulphide.

6th.—Pulse 90; tongue quite moist, brown furring over base; cough a little more troublesome; discharge of pus from wound increased. Mutton-chop and beef-tea. Add one drachm of tinct. of cinchon to each dose of compound senega mixture.

7th.—Pulse 80, full and strong; tongue cleaning; appetite improving; pain in right side increased; fluctuation over ribs; on pressing in direction of wound, about three ounce of pus drained away. Turned patient on left side to allow matter to drain away. Applied compress and adhesive plaister over cavity. To get ol ricini ℥vj. next morning if required.

8th, 10 A.M.—Pulse 76; cough almost better; tongue moist, nearly quite clean; bowels opened; appetite good; quite cheerful and almost well; pain in side better; no discharge of pus; wound granulating.

I need not give the further daily details, suffice it to say the wound was quite healed, and the man up out of his bed on the 12th, and has been engaged at his occupation as a fireman, of course wearing a truss, since 1st February 1866.

I must confess that on the 4th evening after the operation, I had little expectation my patient would recover. There were manifest symptoms of pyæmia, engorgement of the lungs, and failing heart; death seemed imminent, so much so, that I could hardly induce the daughter to apply the mustard, as she thought her father dying.

Was the bi-sulphide useful or not in this case? or was it the tinct. digitalis, by strengthening the weakened heart, and the copious use of stimulants and nutrients, that tided the patient over the danger? Should I meet a similar case again, I would give Richardson's apparatus a trial before operating. I should have stated in the early part of the report, that I had recourse to cold applications to the tumour, but as it is impossible to get ice in a small country town at all times, simple cold fomentation has little effect. I had not Richardson's Apparatus at the time of the operation.

## THE PROSTATE GLAND.

INFLAMMATION—ABSCESS—OPENED THROUGH THE RECTUM  
—SPEEDY RECOVERY.

By P. C. LITTLE, F.R.C.S.I., Etc.

The prostate gland is so intimately related to the urinary and generative organs, that any affection of it demands the early and earnest attention of the surgeon. In old age, it is frequently the seat of inflammatory disease (as described by Sir Everard Home), and of abscess, hypertrophy, calculous, or cancer. In the earlier periods of life, inflammation of a secondary character is the most usual malady of the organ. Of the causes which induce this condition, gonorrhœa is probably the most fruitful. The following case is an example of acute prostatitis of such an origin, and appears to be of practical interest.

March 25th.—P. G., aged 33, an artist, of low stature, healthy appearance, though subject to rheumatism, consulted me for retention of urine since yesterday, with pain at the rectum, tenesmus, and constipation of bowels—the results, he believed, of cold of a fortnight's duration. A tumour, corresponding in position with the distended bladder, filled the hypogastric region as far as the umbilicus. On examining the penis, I observed that its lips were red, swollen, and adherent with a greenish matter, and that slight pressure upon the urethra, revealed a true gonorrhœal

discharge. His efforts to micturate were painful, and ineffectual. With the intention of emptying the bladder, I endeavoured gently to pass into it a No. 6 gum-elastic catheter, without a stilet, but could proceed no further than the prostatic portion of the urethra, owing to an obstruction there of an abrupt character. I was equally unsuccessful with No. 4. I then tried No. 3. With the point of the instrument I carefully explored around the occlusion for the natural passage, which I discovered, much displaced towards the left side, and elongated posteriorly, as I judged from the urine not flowing, until only about an inch of the catheter remained external to the meatus urinarius. The passing of the instrument through the inflamed region was attended with severe pain, sickness of stomach, and fainting. With great comfort to the afflicted man, I drew off about three pints of dark, foetid, strongly acid urine, with mucus in solution—a proceeding which I was obliged to repeat night and morning for about a week. I then made a rectal examination, by passing slowly, though with great suffering to the patient, my right index finger well-oiled through the anus, where it was tightly grasped by the sphincter. The recto-vesical wall was hot, abnormally dry, and extremely sensitive. Beneath the prostate, and especially its right lobe, the tenderness was excessive. The wall-tissue and capsule of the gland felt soft and edematous, and deeper pressure conveyed a lobular sensation.

I ordered the prostate to be freely leeches; afterwards hot poultices to the perineum; the emetico-cathartic mixture, slop diet, barley-water, whey, and ice, if agreeable. No stimulants. Rest in bed.

Next morning.—He felt better, though he slept none; his bowels had been well moved; stomach still sick, tenesmus, and throbbing in the rectum; attempts to pass water distressing and useless; urine still acid, and loaded with mucus; prostate cannot bear to be touched. I directed the immediate application of twelve leeches an inch in front of the anus; hot poultices then; a tablespoonful of alkaline mixture, with tr. opii (gtt. xv.) every second hour; hip-bath, and pulv. ipec. co. (gr. x.) at bed time.

Third day.—Feels easier; had a sharp rigor coming on morning; is chilly yet. Continue the treatment.

Fourth day.—Rested none last night; skin burning; tongue furred, brown in the centre; pulse 120, and nervous; frequent tenesmus, and darting pain, recurring every quarter of an hour, in the rectum, followed by prostration, and despondency.

Having placed the patient upon his left side, his knees flexed, buttocks on the edge of the bed, I examined the prostate. Its right lobe was softer, and less sensitive than before. Its centre appeared of a dusky red, through the speculum, which caused much suffering. I passed through the instrument, to nearly three inches from the anus, a long straight bistoury, and, without pain, made a free incision of more than an inch longitudinally through the dark protruding right lobe, by which I gave exit to about two drachms of coagulated blood, ill-formed pus, and a quantity of bloody serum, with much relief to the patient. I then put up the rectum, a half-grain morphia suppository; advised the continuation of the alkaline mixture; poultices; hip-bath and anodyne at bedtime. The diet, as before, with beef-tea added.

Fifth day.—Slept several hours during the night. This morning he complains of an increase of pain in the rectum. His face is flushed; skin perspiring; pulse 116, small and irritable; stomach sick; bowels confined and tympanitic; prostate very painful on touching. The right lobe presents another prominence larger than the first. I opened it, when about a tablespoonful of matter and grumous blood escaped; after which I introduced a suppository. In the evening I advised that the abdomen should be well stuped with turpentine; and afterwards a large enema of gruel, oil, and turpentine, with tr. opii (gtt. xl.), be administered. The rest of the treatment as before. Add to the diet, chop at dinner, and, during the day, two glasses of wine and water.

Sixth day.—Rested pretty well last night. The bowels

had been freely moved, and curdy matter and blood smeared the last of the stools. He complains of being restless, exhausted, and very sore in the rectum. No. 6 catheter with ease entered the bladder to day. The speculum brought to light a third small abscess also in the right lobe of the prostate. An incision into it let out some matter and serum, and afforded comfort to the patient.

Without giving further daily particulars of the case, it may be sufficient to say that after a few days the urine flowed naturally, all pain ceased; and, by the application of a strong caustic solution to the prostate, with other suitable tonic treatment, the patient perfectly regained his health, and was enabled to resume his occupation in about a fortnight from the setting in of this serious disease.

The symptoms which this case presents are those which generally accompany prostatitis, and which I may be permitted to summarise thus:—

1. Retention of urine.
2. Pain at lower part of rectum, or perineum.
3. Distressing tenesmus.
4. Throbbing at anus.
5. Sympathetic disturbance.
6. Prostatic tenderness.

These conditions leave little doubt as to the nature of the disease. 1. The retention arises from occlusion of the prostatic portion of the urethra by the inflammation, which may either implicate the whole organ, and so concentrically close up the canal; or, what is more usual, may attack one of the three lobes, and so obstruct and displace the urinary passage. In the present case the latter was pushed to the left side, by the inflamed right lobe. 2.-3. The immediate union of this gland with the lowest portion of the intestine, and sphincter ani, account for the pain in the rectum or perineum, and the tenesmus—so urgent and prominent a symptom. 4. At an advanced period, throbbing at the arms was a remarkable feature. When it exists, we may look upon it as announcing the formation of matter. I have observed that this condition more generally accompanies the formation of matter in certain local inflammations than do rigors. In the case before us, there was only one distinct rigor. 5. The general systemic disturbance in this disease, is probably owing to the peculiar nervous relations of the prostate. It is closely united with the great nervous centres, through the "plexus seminalis" of the sympathetic, which, after supplying the vasa deferentia, and vesiculæ seminales, break up into innumerable minute branches, which ramify upon, and terminate in the gland; and, it is a physiological fact, that sensibility is greatest at the extremities of nerves. 6. Tenderness of the prostate, ascertained by digital examination, completes the diagnosis.

The pathology of inflammation of this gland is still obscure in some respects, although much light has been shed upon it by the investigations of Kölleker, Virchow, V. Ellis, Jarjavay, and other modern physiologists and microscopic anatomists.

We may enquire, by what means gonorrhœal inflammation of the prostate is excited?

1. Is it of metastatic origin? 2. Is the virus communicated to the gland by continuity of surface? 3. Do the veins and lymphatics of the urethra carry the poison to the gland upon which they form a net-work? 4. Is it a rheumatic development of gonorrhœa? 5. Or, is it the effect of two or more of these causes united?

We may reasonably believe that it originates in some of these ways; and, in the generality of cases—is propagated, simply by continuity of surface—the inflammation extending along the urethra to the gland through its numerous excretory ducts. What is the character of this inflammation? Is it erysipelatous? or, phlegmonous? It is difficult to discover any rule on this point. But from analogy, we may infer that inflammation of the cellular covering of the organ, will likely assume an erysipelatous type; while, upon the same principle, inflammation of the substance of the prostate, may be phlegmonous. The products of the inflammation are variable, depending upon the part diseased. Inflammation, in one

case, of the covering of the gland; in another, of its excretory ducts; and, in an other, of the organs of secretion, should not be followed by similar pathological results. A careful examination of, and inquiry into the special circumstances of each case, will assist materially in deciding this point, as well as the others referred to.

Viewing the present case under those aspects, I am of opinion the inflammation was propagated to the substance of the prostate, by *continuity* of surface; was intensified by cold, and the rheumatic diathesis of the patient; was phlegmonous, as the high local and general symptoms, and the good effects of the depressing treatment, manifested. The formation of matter in three distinct chambers was peculiar. Many such divisions are made by the strong fibrous processes which pass from the capsule of the gland through its muscular structure. There is no doubt these processes, and the capsule from which they spring, and which is derived from the strong recto-vesical fascia, constitute a principal obstacle to the resolution, or the easy subduing of inflammation of the structures they so firmly and entirely embrace. This fibrous envelope and net work, moreover, form a basis for rheumatic developments, which so greatly aggravate a case of this nature.

The treatment was, I think, rational, and suggested by the circumstances of the case. My first object was to empty the over distended bladder. In this I succeeded by the careful use of a gum-elastic catheter without stilet, as advised by an able and accomplished Irish surgeon, the late Mr. Rind. I need scarcely remark upon the wisdom of that advice. With this flexible instrument, there is much less danger of making false passages, and much more likelihood of insinuating its point through a distorted and inflamed urethra, than there would be with an unyielding one.

The emetico-cathartic mixture produced most useful aperient and diaphoretic effects. The local blood-letting was not followed by the desired results. Here I may call attention to the propriety of direct leeching of the inflamed prostate, and the necessity of confiding that duty to a qualified person, who will perform it *efficiently*. The question arises, should mercury have been administered? I should be slow to give it in such cases where the inflammation confines itself to the gland. I would not hesitate to do so should the disease implicate the bladder or peritoneum, as sometimes happens.

Early incisions for the evacuation of matter are necessary. Neglect on this point may lead to dangerous consequences; such as extension of the inflammation to important adjacent structures, recto-vesical fistula—the abscess having burst into the rectum, or into the neck of the bladder, forming the nidus for a calculus; irritative fever, pyemia, exhaustion, and death. Where and how should the incisions be made? The practice adopted by some of plunging a knife through the perineum into the prostate, seems unscientific and inhuman, and may not achieve the object in view. What are the chief objections to it? A large branch of the pudic artery may be divided; the bladder, rectum, or urethra may be opened, and an intractable fistula created; extravasation of urine, and diffuse cellulitis may ensue. Again, it appears very objectionable to attempt to open a prostatic abscess, the position of which is unknown, by thrusting an inflexible instrument through the urethra in search of it. False canals may thus be made, the natural one, no matter how tortuous, may become still more so; the catheter may not be able to enter the bladder, from the swelling induced, and complete retention may result from this "heroic treatment."

If the matter be in either the right, or left lobe, or the prostatic capsule, which a *tactus eruditus* will soon determine, there can be little danger or difficulty in tapping it through the rectum, and with little or no pain, as in the case under consideration. This method is approved of by Nélaton, and other French surgeons of distinction. A bivalve speculum, of such calibre at the anal extremity as to admit the index finger for exploration, and a long bistoury, with the edge sharp only towards the point, will be most suitable for the operation. Time should be taken for the introduction and divarication of the speculum, on account

of the unusual tonic condition of the sphincter ani in this disease. This strong tonicity appears to me to be the only fair objection to this mode of letting out the matter. On the withdrawal of the instrument, the muscle powerfully contracts, closes up the outlet made for the pus, and prevents any more from escaping. To meet this drawback, in the case before us I recommended active enemata of oil, turpentine, &c., which accomplished my desires. If the abscess confine itself to the middle lobe, or point towards the urethra, I can conceive no more appropriate means of treating it than by incision made through M. Desormeaux's endoscope, improved by Dr. Cruise.

In the after-management of the case, it may be useful to apply nitrate of silver, or some such stimulating astringent, to the abscess, which may readily be done through the instruments of which I have just spoken. It may be necessary to draw off the water after the evacuation of the pus. Should it be so, we shall have a safe guide into the bladder, by carefully pressing the instrument along the upper surface of the urethra—a rule for the introduction of the catheter inculcated by Mr. Butcher.

### ON DREAMING, CONSIDERED ESPECIALLY IN RELATION TO INSANITY.

By THOMAS MORE MADDEN, M.R.I.A.,

LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND, MEMBER OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, AUTHOR OF AN ESSAY "ON INSANITY AND THE CRIMINAL RESPONSIBILITY OF THE INSANE," "ON CHANGE OF CLIMATE, A GUIDE FOR TRAVELLERS IN PURSUIT OF HEALTH," &c., &c., &c.

(Continued from page 361.)

#### IX. THE REAL AND THE APPARENT DURATION OF DREAMS.

THE rapidity with which events that appear to have occupied long periods of time pass before the mind in dreams is another very interesting question. "In dreams," says Dr. R. R. Madden, "the time occupied by the playing out of entire scenes of an ideal drama, the wonderful incidents of which could not be described (were they to be written down) in half an hour, is often hardly appreciable; sometimes it is estimated by seconds, at other times by minutes."<sup>(1)</sup> This fact is so generally admitted that I have referred to it only in consequence of some remarks in the Rev. Dr. Wills' learned paper "On Dreams," in which he says—"It seems probable that most dreams occupy the same time which the same succession of ideas would in waking; there seems at least no ground for the contrary opinion."<sup>(2)</sup>

It would be easy, however, to quote numerous instances in refutation of this theory of Dr. Wills'. Very interesting illustrations of the inaccurate perception of the time occupied by dreams are given in Lord Brougham's "Discourse on Natural Theology," and also in Dr. Winslow's work, "On Obscure Diseases of the Brain." Dr. Abercrombie narrates the following instance of this:—"A gentleman dreamt that he had enlisted as a soldier, joined his regiment, deserted, was apprehended, carried back, tried, condemned to be shot, and at last led out for execution. After all the usual preparations a gun was fired; he awoke with the report, and found that a noise in an adjoining room had both produced the dream and awakened him."<sup>(3)</sup> The late Sir B. Brodie's remarks on this topic are very suggestive. He says—"If we were to pursue this subject it would lead us to some curious speculations as to our estimate of time, and the difference between the real and the apparent duration of life. . . . The apparent duration of time is longer or shorter in proportion as a greater or smaller number of different states of mind follow each other in succession."<sup>(4)</sup>

From the foregoing observations we may, I think, arrive at the conclusion that neither of the two theories—one or other of which are most generally adopted with regard to

(1) Dr. R. R. Madden, "Phantasmas, or Illusions and Fanaticisms of Protean Forms Productive of Great Evils," vol. i., p. 92. London. 1857.

(4) Sir Benjamin Brodie, "Psychological Inquiries," part 1st, p. 149. London. 1862.

dreams—*i.e.*, that which teaches that dreams depend on the association of ideas, on the one hand, and that which supposes their origin in bodily sensations on the other—afford any satisfactory explanation of the phenomena of dreaming, though, as has been already shown, both these causes, either alone or combined together, frequently do influence the state of the mind in sleep. But to assert that a dream is occasioned by some physical sensation, or by the association of ideas, affords, I think, little insight into the real nature of a mental condition in which the images set before us, and the impressions produced upon the mind are as vivid, and apparently as actual, as those transmitted through the waking senses, and far more distinct than those which can be called up by any voluntary exercise of the memory. Nor do these theories in any wise explain or even throw the least light upon the singular exaltation of the mental powers, or at any rate of certain faculties of the mind, such as the imagination or the memory, which occasionally occur in the dreaming state.

Too many well-authenticated facts are recorded concerning this mysterious condition of the mind to permit us to doubt that manifestations of a nature which cannot be explained by any reference to physical laws have taken place during sleep. To all these cases I would apply the words of Bossuet, when speaking on the same subject—"Il y a," he says, "des choses tres admirables qui échappent a notre vue et qui n'ont ni moins vrais, ni moins desirables, quoiqu'on ne les puisse ni comprendre ni imaginer."<sup>(1)</sup> I have collected a very large amount of facts bearing on this branch of the present inquiry. This, however, would not be a proper place for entering into the consideration of so extensive, though so important and interesting, a topic. But I would gladly recur to it should I be again afforded an opportunity of doing so. The subject, however, which we have now to consider is one of a very different character from the foregoing—namely, the physiology of dreaming.

#### X. THE PROXIMATE CAUSE OF DREAMING.

It is probable that dreaming is intimately connected with the peculiar state of the cerebral circulation during sleep. In proportion to its size no part of the body receives so large a supply of blood as the brain, and none of the other organs of the human frame are provided with such exquisite adaption of structure for the maintenance of a healthy and constant equilibrium between the contents of the veins and arteries as it is. I should apologize to this learned Society for alluding to what must be familiar to every member present, were it not that this reference to the physiology of the cranial circulation is indispensable to the consideration of the physiology of dreaming.

We should therefore bear in mind that, in consequence, probably, of its high vitality and complex organization, the brain requires and receives a constant and very large supply of blood, amounting, as physiologists assert, to no less than one-fifth of the entire quantity of blood in circulation in the body. And certainly in no part of the frame do we find such ample provision for the supply of a due amount of arterial blood, and, more especially, such a provision made for the constant equilibrium between the relative proportions of venous and arterial blood, as within the cranial cavity, provided as it is with four great arterial trunks, numerous veins, sixteen large sinuses and a most remarkable system of anastomosis, not confined as in other parts to the capillary branches, but occurring, as in the circle of Willis, directly between the large arteries. Moreover, the cerebral vessels are peculiarly fitted for the maintenance of the balance of the circulation between their veins and arteries by the middle or contractile muscular coat of the cerebral veins being developed in a way which does not exist in other parts of the venous system.

The majority of recent physiologists appear to agree with Mr. Durham, in the conclusions he arrived at from his elaborate experiments on this subject, namely, that—"During sleep the brain is in a comparatively bloodless condition; and the blood in the encephalic vessels is not only diminished in quantity, but moves with diminished

rapidity."<sup>(1)</sup> The following case, observed at Montpellier, very strongly confirms this opinion:—A woman having lost part of the skull, from disease, the corresponding portion of the brain and its membranes remained exposed. "When she was in a deep or sound sleep, the brain lay in the skull almost motionless; when she was dreaming, it became elevated; and when her dreams (which she related on waking) were vivid or interesting, the brain was protruded through the cranial aperture."<sup>(2)</sup> It must be borne in mind that in this case, and in those in which a portion of the cranium has been removed purposely, as was done in Mr. Durham's most interesting experiments, the brain and its membranes were in an abnormal state, and therefore such observations must be regarded as more or less unsatisfactory and liable to error. Indeed, so far are we yet from an accurate knowledge of the true vascular condition of the brain during sleep, that in a work published within the last few years by a very distinguished member of the Institute of France, we find it asserted that "during sleep the brain is in a state of passive congestion."<sup>(3)</sup>

Opposite as these opinions may appear, it will, I think, be found that dreaming is best explained by adopting both these conjectures in part. If we combine these theories thus, we may suppose that dreams are caused by a partial relaxation of the tonic contractility of the cerebral veins, which limits the amount of blood that passes through these vessels, and that thus the different parts of the encephalon may be in very different conditions at the same time. For instance, the blood may be moving with much greater force and rapidity through the capillaries of the base of the brain, than in those of the superior portions of the hemispheres. Or, in other words, that something like active congestion, confined to a small portion of the brain, occurs. And if, as it has been conjectured, the localities or parts of the cerebrum are subservient to the several functions of the mind, (a point on which I offer no opinion, however), by this theory we might more easily comprehend the phenomena of a state marked by the activity of certain of the mental powers, whilst the rest are for the time suspended. But, without any reference to phrenological views, I think that the state of the cerebral circulation during sleep seems to be immediately connected with dreaming, and probably there is then some alteration in the vascular condition of the superficial gray structure of the brain during sleep modifying the character of the nervous force evolved by it. What the nature of this supposed change in the action of the brain during sleep consists in, is a matter which we must necessarily remain utterly ignorant of. For, in truth, nothing is known of the nature of the cerebral action by which nervous force is evolved at any time or under any circumstances; and modern physiologists have done little more than re-echo the often repeated and as often contradicted assertion, that all the operations of the mind are accompanied by a molecular change in the cortical or vesicular substance of the brain.

If this theory be correct, it does not lessen the interest attaching to this most remarkable condition of the mind. The physical change in the vesicular structure of the brain, which I have described as probably connected with dreaming, if it does really occur at all, as I have supposed (for where proof is impossible a reasonable conjecture is all that can be offered in its place) is merely an accompaniment, and cannot be regarded as the cause of dreaming. For this vesicular change could only take place in consequence of some primary existing cause, which we may suppose to be the action of the mental principle.

#### XI. THE PATHOLOGICAL INDICATIONS FURNISHED BY DREAMS.

Having now discussed the physiology of dreaming, we may next proceed to consider its pathological and medical aspects. In the earliest annals of every country we find that the interpretation of dreams was a part of the office of the physician. In the treatise "On Dreams," commonly

ascribed to Hippocrates; in the last volume of "Saxon Leechdoms," published in 1866 by direction of the Master of the Rolls; and in an ancient Irish Medical MS., a translation of which, by Mr. O. Longan, may be found in the MS. collection of the Royal Irish Academy, we find sufficient proof, without referring to other authorities, of the same importance being attached to those signs of disease which were supposed to be furnished by dreams, in countries and ages very remote from each other.

Opinions that are very wide-spread and generally adopted are seldom devoid of some foundation in truth; and although the subject I am treating of has now passed completely out of the hands of medical writers, who regard it as something puerile and unworthy of scientific investigation, I shall endeavour to show that this view of the matter is not altogether just, and that something may occasionally be learned by attending to the peculiar character of our patient's dreams in certain cases.

The phenomena accompanying any deviation from the normal quantity of blood in the encephalon, and the functional disturbance of the brain resulting therefrom, as evinced under all circumstances that occasion either an augmented or diminished supply of arterial blood, naturally lead us to anticipate that similar circumstances will act still more potently in sleep, when the intellectual operations are more directly under the influence of physical and internal causes.

The early physicians were evidently aware of this; thus, the "Father of Physic," or at least some cotemporaneous Greek physician, laid down the theory that—"Such dreams as represent at night a man's actions during the day, and exhibit them in the manner in which they occurred, namely, as performed well and justly deliberated, these are good to a man, and prognosticate health, inasmuch as the soul perseveres in its diurnal cogitations, and is not weighed down by any repletion, evacuation, or any other external accident. But when the dreams are very opposite to the actions of the day, and when there is a conflict between them—when this happens, I say, it indicates a disorder in the body; when the contrast is great, the evil is great, and when the one is small, the other is small also."<sup>(1)</sup> An English philosopher of the seventeenth century, Thomas Hobbs, propounds the following theory on this subject:—"And seeing dreams are occasioned by the distemper of some of the inward parts of the body, divers distempers must needs cause different dreams."<sup>(2)</sup>

A renowned physician and philosopher of the same century, Guy Patin, says:—

"Il est constant que l'on peut connaitre par les songes quelque dispositions corporelle. Je suis la-dessus du sentiment de Sainte Thomas, quand il dit.—"Medici dicunt esse intendendum somnis ad interiores dispositiones." En effect, les malades songent d'ordinaire autrement que ceux que se portant bien; les melancholiques autrement que les sanguins, les bilieux autrement que les pituiteux, mais je m'en tiens la, sans tirer d'autres conjectures sur les choses libres et de pur hazard, jusqua ce que je croye qu'il yait du surnaturel dans ce qu'on a songe; alors je rappelle dans ma memoire l'histoire de Joseph, de Daniel, &c., pour m'y soumettre comme a' des moyens dont l'Eternel se sert, pour faire connaitre aux hommes ses volentez."<sup>(3)</sup> I regret exceedingly that my space obliges me to omit Sir Thomas Brown's observations on this topic in his most eloquent work, the "*Letter to a Friend on the death of an intimate Friend.*"

Albers, as cited by Baron von Feuchtersleben, enumerates the following as among the most approved signs to be obtained from the medical interpretation of dreams. He says:—"Lively dreams are, in general, a sign of the excitement of nervous action. Soft dreams a sign of slight irritation of the brain; often, in nervous fevers, announcing the approach of a favourable crisis. Frightful dreams are a sign of determination of blood to the head. Dreams

about fire are, in women, signs of an impending hæmorrhage. Dreams about blood and red objects are signs of inflammatory conditions. Dreams about rain and water are often signs of diseased mucous membranes and dropsy. Dreams of distorted forms are frequently a sign of abdominal obstructions and disorders of the liver. Dreams in which the patient sees any part of the body especially suffering, indicate disease in that part. Dreams about death often proceed apoplexy, which is connected with determination of blood to the head. The nightmare (incubus, ephialtes), with great sensitiveness, is a sign of determination of blood to the chest." "To these," says Baron Feuchtersleben, "we may add that dreams of dogs, after the bite of a mad dog, often precede the appearance of hydrophobia, but may be only the consequences of excited imagination."<sup>(1)</sup>

Dr. Forbes Winslow quotes several cases in which dreams are said to have been prognostic:—"Arnauld de Villeneuve dreamt one night that a black cat bit him on the side. The next day an anthrax appeared on the part bitten. A patient of Galen's dreamt that one of his limbs was changed into stone. Some days after this leg was paralysed. Roger D'Oxteyn, Knight of the Company of Douglas, went to sleep in good health; towards the middle of the night he saw in his dream a man infected with the plague, quite naked, who attacked him with fury, threw him on the ground after a desperate struggle, and, holding him between his open thighs, vomited the plague into his mouth. Three days after he was seized with the plague, and died. Hippocrates remarks that dreams in which one sees black spectres are a bad omen."<sup>(2)</sup>

So far we have traced the literature of this subject, from the earliest time down to the latest work of authority on psychological medicine, and it only remains now to add a few practical observations on the signs of disease—especially of mental disease—furnished by dreams occasionally.

Fearful dreams, if frequently repeated, may eventually influence the permanent state of the mind, and considering the close resemblance between the phenomena of dreaming and insanity, which Sir H. Holland defines as—"a waking and active dream,"<sup>(3)</sup> we may expect that the former condition, if prolonged, might pass into the latter state. Insanity occasionally does commence in a dream that continues after the cessation of sleep, and cases are recorded in which persons recovering from mental alienation were nightly disturbed in their dreams by the same hallucinations which had previously haunted them in the waking state<sup>(4)</sup>

Esquirol regarded dreams as capable of furnishing valuable indications in some obscure cases of insanity in which the subject of the mental disorder was carefully concealed during the day, but was revealed in sleep by watching the patient's dreams. M. Briere de Boismont also records several cases in which the patient's dreams lead to a discovery of the nature of the mental disease from which they suffered.<sup>(5)</sup>

The derangement of the cerebro-spinal functions accompanying fever is, in all cases, greatest towards night, at which time, even in mild cases, some degree of delirium or wandering is commonly observed. Now, if this take place while the patient is still awake, and subject to the influence of external impressions, how much more readily will such derangement be produced when the mind is no longer under the correction of the senses. The disturbed dreams of fever-patients are probably caused by the general vascular excitement, by some local irregularity of the cerebral circulation, and, perhaps, more directly, by the action of the fever-poison in the blood on the vesicular structure of the brain. And to the imperfect elimination of this poison from the blood, we may also attribute the painful and disagreeable dreams which often continue for some time to disturb the repose of persons convalescing after severe attacks of fever.

## SPECIFICS.

By E. H. MARSH, M.D., T.C.D.

LET us allow a certain place to specifics, but let us recollect that they really are conditional advantages, and most imperative is the necessity that all requirements should be met before the remedy takes up its position and maintains it, and most true it is that all that is true and enduring in principle falls back upon the original law.

To restore unhealthy conditions to the state of health means, therefore, not to apply a specific to the disorder which is apparent, unless in every other point the health of the whole of the numerous functions is complete. Then, if necessary, the specific does its part; supposing, always, that the balance of all the other functions is thoroughly adjusted. Of specifics, we may say, for conscience sake, there are two kinds: one, such as act decidedly, and at once, on any simple disorder; and another class which become such from the place they have in bringing about healthy action in the progress of cure. We are all familiar with the names of such specifics as bark, quinin, colchicum, copaiba, powder of iodine and bromine, in combination with potass. soda, gnaicum, antimonii, potassio, tart., strychnia, aloes, &c., &c., and they certainly act specifically where there is nothing to embarrass and prevent their efficacy.

The tincture of iron in the advanced stage of acute dropsy, from anæmia, in catarrhal discharge of the mucous surfaces of the bladder and uretus, and such restoratives as reproduce red colouring matter in the blood, act specifically, but in this more limited sense, more certainly as strengthening the circulation and restoring the functions, more like the combination which is effected by means of nutriment as far as iron only is taken into the account, thus we regard here also the astringent effect of the muriatic acid with the iron. In most instances which are brought under our notice there is general disorder of the whole system, that it must be our first object to set up a general improvement of healthy actions before the specific can take effect. There really is a great deal to be done before the system is in a state to receive specific medicines, even when they are applicable, and it is not possible after they are used to continue them very long, before the attention is again drawn from them to the condition of other states which need to be considered; and also in all chronic disorders, it is quite essential to fight against the prevailing disease or tendencies by all other requisites. If once the diathesis is formed you can but hope to palliate, and it is to prevent this that so much effort and resolution, morally and physically, are to be enjoined.

In short, so truly are most said to fight out the battle of living, and the *savoir vivre* as well as the battle of life.

## Hospital Report.

## LONDON HOSPITAL.

A CASE OF MALIGNANT DISEASE OF THE BRONCHIAL GLANDS, KIDNEYS, SUPRA-RENAL CAPSULES, PANCREAS, AND MESENTERY.

Under the care of Dr. HERBERT DAVIES.

(Reported by Mr. McCARTHY, Assistant Resident Medical Officer.)

J. G., æt. 43, an ostler, was admitted into Fitzgerald Ward, January 1st, 1867.

He was very pale and emaciated, had a rather vacant expression of countenance, spoke in a listless hesitating manner, and complained of nothing but weakness. He stated that he had never had any acute illness; that all of his family were healthy, and that his present feeling of weakness and depression had been gradually increasing for some months. No satisfactory history could be obtained from him, but it was ascertained that, before applying for admission here, he had attended as an out-patient at the Victoria Park Hospital, under the care of Dr. Sutton, who

has kindly permitted me to extract from his notes the following particulars of the man's then condition:—

"He complains of being weak and low; feels as if there were a lump in his throat; has no cough.

"There is dulness over the lower third of the left lung posteriorly; no dulness anteriorly.

"Respiration much more feeble over left than over right lung; expiration everywhere prolonged.

"Tactile vocal fremitus diminished on left side."

This was about the beginning of December, 1866.

At the time of his admission here it was found that there was absolute dulness on percussion all over the left lung, both back and front; very feeble respiration; absence of tactile vocal fremitus, and greatly diminished vocal resonance throughout the same region; respiration over the right lung was puerile.

He coughed a little occasionally, but did not expectorate anything.

The position of the heart was normal. After he had been in hospital some weeks, a loud, systolic bruit was detected at the left apex of the heart, which had certainly not existed when he was first examined.

The urine was abundant, acid, sp. gr. 1018, without albumen. No microscopic examination was made, as it appeared normal in every respect.

The diagnosis in this case was extremely difficult. It was doubtful whether to regard it as a case of pleuritic effusion, or of extremely thickened pleura, the result of old disease. There were objections to both of these. There was no history of any acute illness. The non-displacement of the heart, and the fact that he could lie on his right side without any inconvenience, contra-indicated pleuritic effusion, and the extremely feeble respiration, the absence of tactile vocal fremitus, the impaired vocal resonance, and absolute dulness on percussion over the entire left lung, were opposed to the supposition of a thickened pleura.

The general opinion was, on the whole, in favour of pleuritic effusion, but so doubtful did it appear, that Dr. Davies was reluctant (fortunately, as the result proved) to assent to the insertion of a trochar, which had been suggested as a ready method of solving the difficulty.

The treatment adopted was: Good diet, tonics, and counter-irritation over the left side by flying-blisters.

There was no improvement in the patient, who seemed to be becoming more and more feeble every day. About four weeks after his admission he had a fit during the night, in which he foamed at the mouth, struggled a good deal, and then sank into a kind of stupor. The next morning, on recovering, he declared that he never had had any similar attack before, and his wife confirmed his statement.

His urine was examined three or four times after this, but nothing abnormal was discovered.

He continued in much the same condition for some weeks, and at last died, apparently from exhaustion, March 22nd, 1867.

The post-mortem was made by Dr. Sutton, pathologist to the hospital, from whose report the following account is taken:—

The body was much wasted; rigor mortis well-marked; no œdema.

On opening the thorax the pleura were found to be adherent throughout. At the root of the left lung was seen a large growth, firmly connecting the heart and lung, so that they had to be removed together. The weight of both together was four and a-half pounds. This growth was hard and firm, and was much larger posteriorly than anteriorly. It seemed to have commenced in the bronchial glands at the base of the left lung, and had completely surrounded the left bronchus, which was so compressed by it as to have altogether lost its tubular form, and presented the appearance of a narrow fissure. The left lung was collapsed, airless, and sank in water. On section a number of yellowish white spots were visible amidst the collapsed lung tissue. These proved to be the mouths of bronchial tubes.

On cutting through the growth, so as to separate the

left lung from the heart, a large mass of soft malignant tumour became visible, exceedingly juicy, so much so that on slight pressure a quantity of thick milky looking fluid exuded from the divided surfaces of the mass. This growth had invaded the pericardium, causing acute inflammation, by which the surfaces of the pericardial sac had been glued together. The right lung weighed twenty-two ounces. It was much congested, soft, and easily torn. In one of the bronchial glands, at the root of this lung, was a deposit similar to that in the left bronchial glands.

The heart was healthy, as were also the liver and spleen.

Both supra-renal capsules had been replaced by malignant growths, the right so completely, that it could not have been recognised but for its position.

The kidneys together weighed 2 lbs. and three and a-quarter ozs. The left was almost completely converted into a large malignant mass of a greyish white appearance. There were also several ecchymoses, as if a quantity of blood had been extravasated.

The right kidney was smaller, and about one-half of its structure was healthy, the other half being occupied by malignant growth.

The pancreas was also involved in this cancerous disease.

In the lesser omentum was a large mass about the size of an orange—heavy and similar in appearance to the other growths.

In this case there was nothing during life to have suggested what was shown by the post-mortem examination to have been the actual disease. The appearance of the man was not inconsistent with cancer, but yet the cachexia was not so marked as to suggest it.

The complete absence of pain or distress throughout the entire progress of the disease, even after the invasion of the pericardium, which probably occurred subsequently to his admission into the Hospital, was very remarkable. It is to be regretted that the urine was not examined microscopically. Another case, however, has recently been met with in the Hospital, where both kidneys were even more extensively involved in cancerous disease; but, notwithstanding repeated microscopic investigations, nothing was discovered to indicate the renal condition, which was not even suspected during life.

## NEW INVENTIONS, & c.

### DR. RICHARDSON'S STYPTIC COLLOID.

THIS preparation was brought before the Profession at the first of Dr. Richardson's lectures, to which we have previously directed attention. It consists of ether and alcohol, saturated with tannin and gun-cotton. When diluted with an equal quantity of ether, it may be used in the form of spray. Undiluted, it is applied with a brush. The fluid coagulates the blood, serum, albumen, liquor sanguinis, and pus. When brought into contact with a wound, the ether and alcohol are volatilised by the heat of the body, and the tannin and gun-cotton are left intimately combined on the surface. The tannin converts the albumen into tough leathery membrane. The cotton gives a certain consistency. Numerous experiments, some of which were repeated at the lecture in question, show that solidification of the fluids is not the only effect, but that deodorisation is produced by this application. As the animal tissues form a combination with the dressing, the exclusion of the air is perfect, and the healing process uninterrupted. After operations, or in recent wounds from accident, the treatment by this process is most simple, and reduces the case to a state similar to that of subcutaneous lesion.

The edges are to be brought carefully together (with a suture when necessary) in the usual way. Then the *styptic colloid* is to be applied freely with a brush. A thin layer of cotton wool soaked in the colloid may then be laid along the line of the wound, and, if thought advisable, a further layer of the liquid laid on with the brush. In a suppurating wound it is only necessary to brush over the surface, so as to leave a layer of colloid upon it.

Compound fractures may, in Dr. Richardson's opinion, be most advantageously treated with this new remedy. The styptic colloid may be poured into the wounded cavities, and thus the case reduced to one approaching simple fracture.

A great advantage of this dressing is that it need not be removed unless there were fetor from the wound prior to its application, or unless it should be raised by fresh discharge, or symptoms of suppuration should occur.

Finally, this styptic forms a base for other remedies, among which may be named creasote, carbolic acid, quina, iodine, iodide of cadmium, bichloride of mercury, morphia, cantharidine, &c. Messrs. Robbins and Co., 372, Oxford-street, W., are the manufacturers.

## Reviews.

CHEMISTRY: "with Experiments, and a Comparison of Equivalent and Molecular Formulæ." By CHAS. LUDLOW BLOXAM. John Churchill and Sons. London, 1867.

It might almost be said that Chemistry had been over-done, so numerous have been the works written upon this science—the years 1866 and 1867 having been particularly prolific in this respect. The result of this redundancy of literature is, as might be naturally supposed, a sameness in many of the works to those that have gone before them. This is illustrated in the latter or organic part of the chemistry before us—not for a moment that we wish to attribute plagiarism to the author, but we think this part savours too much of compilation. We have commenced by saying the worst we have to say of this otherwise excellent work. Thoroughly practical at all points, there is a wonderful amount of information in this medium-sized treatise on Chemistry. The work is evidently written from a lecturer's point of view, and is freely interspersed with experiments, which are extremely well arranged to illustrate the gradual unfolding of the science. A great number of these experiments are connected with explosive compounds, the author having a view to the requirements of military students. The arrangements of the apparatus for many of the said experiments are ingenious, and well shown in the numerous illustrations with which the book is interspersed. It is quite a treat to find the standard "cuts" of distillatory apparatus, the orthodox retorts, somewhat differently arranged. Public lecturer's may pick up a hint from this part of the work.

Although the author explains the new changes in theoretical chemistry, he does not adopt or use them any further than is necessary for such explanations. We think he is wrong on this point, but in the present state of science we are, at the same time, compelled to admit that he is entitled to adhere to the old system, whether, as a matter of policy, it is desirable, a few more years will prove. Prof. Bloxam's book is the only one of importance published within the last few years that has retained the old equivalents.

We cannot do better than give the following extract as illustrative of the arrangement of this work:—*Nitric oxide* or *binoxide of nitrogen* is usually obtained by the action of copper upon diluted nitric acid.

$4 (\text{HO NO}_3) + \text{Cu}_3 = 3 (\text{Cu O. NO}_3) + \text{NO}_2 + 4 \text{HO.}$

"300 grains of copper turnings or clippings are introduced into a retort, and three measured ounces of a mixture of concentrated nitric acid with an equal volume of water are poured upon them. A very gentle heat may be applied to assist the action, and the gas is collected over water, which absorbs the red fumes ( $\text{NO}_2$ ) formed by the union of ( $\text{NO}_2$ ) with the air contained in the retort."

Nitric oxide is distinguished from all other gases by the production of a red gas, when the colourless nitric oxide is allowed to come in contact with uncombined oxygen, the presence of which, in mixtures of gases, may be readily detected by adding a little nitric oxide. The red gas consists chiefly of nitric protoxide ( $\text{NO}_2$ ), but it often contains also some ( $\text{NO}$ ) nitrous acid.

"The combination of nitric oxide with oxygen, may be exhibited by decanting a pint bottle of oxygen, under water, in a tall jar filled with water coloured with blue litmus, and adding to it a pint bottle of nitric oxide. Strong red fumes are immediately produced, and on gently agitating the cylinder the fumes are absorbed by the water, at the same time reddening the litmus. The water will now have been absorbed to half its

volume, and if another pint of nitric oxide be added, the remainder of the oxygen will be absorbed, showing that two volumes of nitric oxide combine with one volume of oxygen forming the nitric peroxide, which is absorbed by the water."

A voluminous and complete index finishes one of the most practical manuals of chemistry that has been written for some time. In this index the symbols are given, an excellent plan, which, if we mistake not, first emanated from Dr. Williamson with his "Manual for Students." C.R.C.T.

INTRODUCTION TO CHEMICAL PHILOSOPHY. ACCORDING TO MODERN THEORIES. By Dr. A. C. WURTZ, F.R.S. Translated by Wm. Crookes, F.R.S. London: Dutton, Wine Office Court.

THOSE of our readers who retain a vivid interest in the progress of modern chemistry, and what medical man does not? will be glad to hear of a very neat and portable English translation of the valuable introduction of Dr. Adolphe Wurtz. The work has long been known on the Continent as one distinguished for the clearness of its statements, the excellent arrangements of its facts, the justice it does to all labourers in the field, and the condensed account it gives of the subject. The book traces accurately and fairly the changes that have successively taken place in the opinions of chemical investigators and reasoners, respecting the laws of combination, the theories of equivalents, atoms, &c., and thus furnishes a valuable historical sketch of the rise and progress of Chemical Philosophy. By this method the student is led, as it were, through the same paths that earnest workers have already trodden, and at last landed in the open space that lies before him for exploration.

To descend to a few particulars. The first part of this volume is devoted to equivalents, atomic weights and molecular weights; the second to the theory of types and atomicity; the third to the connection between organic and inorganic chemistry; the conclusion gives the dualistic hypothesis, the unitary system, and the new chemistry. It may be thought that for the development of all this a very ponderous volume would be required, but happily Dr. Wurtz has the rare gift of expressing himself in few words, and while nothing seems to be omitted, and there is no stint of tabular matter, the present translation only occupies a thin volume of 192 pages in small 8vo. Every earnest student may, therefore, rejoice that in a little book of moderate price he can possess such a treasure.

As the work of Dr. Wurtz is so well known, and as it has already been published in the columns of the *Chemical News*, we ought, perhaps, to confine our further observations to the labours of the translator. These have been by no means light, but they have been carried out in a manner that leaves nothing to be desired.

The perfection of translation is to present the ideas of the author in another language so naturally, that the reader would not suppose them to be really transferred from another tongue by an interpreter.

In scientific works this is particularly difficult, and even skilled linguists often fail to bestow the attention necessary to success.

We are bound to pronounce this translation by Mr. Crookes excellent.

The most recondite parts of the work are expressed in such English, that any one might readily imagine them to be the utterances of a fluent London lecturer. Page after page may be read without noticing a foreign idiom. Whatever dryness or dullness appears in the book belongs to the difficulty of the subject itself—not to the author's style, nor to the translator's version. We think, therefore, Mr. Crookes may be fairly complimented on the manner in which he has accomplished his task. The *Chemical News* did good service by publishing Dr. Wurtz's treatise, and its re-publication in the present compact form cannot fail to give satisfaction to all lovers of Chemical Philosophy.

#### CURRENT LITERATURE.

THE *Westminster Review* contains its usual number of thoughtful articles, amongst which we may specially mention the one on Thomas Hobbes, the philosopher of Malmesbury, whose character and works have, in the present century, excited so much discussion. The portion of this Quarterly most interesting to our Profession is the con-

temporary scientific literature, in which will be found brief notices of many new medical books.

The *New York Medical Journal*, for March, which has only just reached us, is distinguished by a most important article, filling twenty-seven pages, on "Osteo-Myelitis," written by Dr. Lidell, Inspector-General of the Army of the Potomac. It consists of an exhaustive memoir, which was read before the New York Academy of Medicine last December, and to which every one in search of reliable information on the subject will naturally turn. In the report on the "Progress of Medicine," some of the cases of Dr. Lyons are quoted from our columns.

The *American Journal of the Medical Sciences* opens with an elaborate article on wounds of the internal jugular vein, which treats of them with special reference to the safety of the ligature, and comprises a statistical account of eighty-six cases. This article is from the pen of Dr. Gross. Then follows rupture of the abdominal and pelvic viscera, by Dr. Lidell, which is especially devoted to injuries to the bladder, including those occasioned by fire-arms. Dr. McClellan, of the United States Army, contributes an article on the internal use of chloroform in intermittent fever. Dr. Livingston writes on ether in laryngitis with exudation of lymph. Dr. Noyes, of New York, treats of the ophthalmoscope as an aid to diagnosis in diseases of the brain. Dr. Smith of the United States Army gives an account of malignant pustule as it appeared in Mexico in 1865. Next we observe a very interesting account of the appearance of the membrana tympani and fauces in 296 cases of deaf-mutism, as found on examination by Drs. Roosa and Beard. Of these cases 61 per cent were acquired, and 39 per cent congenital. The membrane was opaque, or sunken, or showed signs of former inflammatory action in the cavity, in 118 of the congenital cases. It was congested in 16; normal in 22; absent in 14; indistinctly seen on account of wax in 8; and in 4 there was calcarious concretion. In 80 of the cases of acquired deaf-mutism, the writers found the membrane present. In 29 it was perforated; in 3 it was not distinctly seen; there was calcarious concretion in 2. Of all the cases more than two-thirds exhibited some chronic faucial disease. After this paper there is a case of cure of aneurism of the common carotid artery by compression, related by Dr. Kerr; a case of removal of polypus from the inferior anterior surface of the eighth vocal cord by Dr. Cohen, and a description of an invalid bed, by Dr. Cutter of Boston. Such are the original communications in this number of the *American Quarterly*. The Reports of societies, reviews, and bibliographical notices, as well as the summary of progress in the various departments, are all as copious as usual. We look with much interest to the appearance of this journal which continues under the able editorship of Dr. Hays, and worthily represents American medicine.

THE GREAT NORTHERN HOSPITAL.—Amongst the enormous wealth of the metropolis, and the many munificent legacies bequeathed to various charitable institutions, one of our noble hospitals, at least, seems not to be in fortune's path. Last Thursday, at the celebration of the annual festival, it was admitted that, notwithstanding the great amount of good it had done, and was doing, in the centre of a very poor locality, unless funds were forthcoming, they must of necessity close the doors of a large portion of the building. We trust, however, that the eloquent appeal by the chairman, on behalf of so valuable an institution, will result in materially aiding the committee and staff in the execution of so good a charity.

## REGISTERED FOR TRANSMISSION ABROAD.

THE MEDICAL PRESS AND CIRCULAR is published simultaneously in London, Edinburgh, and Dublin, every Wednesday morning.

Price 5d. Stamped 6d.

By Post to Annual Subscribers, £1 2 6  
 ,, If paid in advance, 1 1 8

### PHARMACEUTISTS IN ENGLAND.

THE practice of Pharmacy can never be an indifferent subject to the great body of the Medical Profession, and the laws regulating it, and proposed changes in them, consequently possess for our readers a lively interest. Even were Pharmacy absolutely divorced from medical practice, it would be necessary for prescribers to make themselves acquainted with its details, and friendly co-operation for the public weal would be required. We cannot, therefore, consider ourselves disinterested spectators of the animated debate now going on as to the proposed new Pharmacy Act, which would throw all power into the hands of the Pharmaceutical Society, and compel all outsiders to join that useful body. If the dispensing of prescriptions is to be protected at all, and while other branches of medical practice are protected, it is only logical to do so; we know no better way than committing the whole control of Pharmaceutists to a society that has considerably raised the status of the craft. To multiply privileged corporations is simply ridiculous, and medicine and surgery have long suffered from the number they have to support. The proposal is therefore reasonable, that in future no one should practice Pharmacy who had not been examined and approved by the Society. The point which has raised the storm is the manner in which the chemists and druggists now in business, but not members of the Society, are to be persuaded to join it. The Council has offered large concessions—too large in the opinion of many, who resent the intrusion of unexamined men into their ranks, and fear the value of their diploma will thereby be diminished. It is impossible to deny the justice of this argument, or to conceal the fact that a disguised sale of a qualification is unworthy of any respectable corporation, although it has been practised by those who sway the destinies of higher branches of the healing art. The act, however, has, in every instance, subjected the *bona fide* holders of those diplomas to the greatest annoyances.

But the chemists and druggists will not come in on other terms. What then is to be done? It seems to us that there is a simple and satisfactory mode of action which would be just to all, and it is a plan that has been already successfully carried out.

The Apothecaries' Act provided that those in practice on its being passed, should continue to enjoy all their privileges, but that no one should afterwards commence practice without the license of the company. The result of this is, that even now a few men are inscribed on the "Medical Register" as "in practice prior to 1815." That is their qualification. Of course, every year the number of these practitioners decreases, and they will soon disappear from the list. What is to prevent a similar course with the Pharmaceutical Society? Let them get a stringent act to prevent any one practising Pharmacy in future—and reserve the rights of the existing chemists and druggists. But they might go one step further. The Apothecaries' Company had no power to take a census at once, and register the name of every one in actual practice, and consequently had in some cases a difficulty. Let every one be compelled to register himself during the year 1867, or forfeit his privileges. Thus there would be an end to all discussion as to who is and who is not legally entitled to dispense medicines, sell poisons, &c. A further step might be gained by admitting all registered chemists and druggists who pleased to the examinations, without proof of study or any other restriction. The multiplicity of grades in the Society—the distinction between associates, members, and pharmaceutical chemists, is, in our opinion, unadvisable, if not frivolous. One qualification for all who practice Pharmacy is what is needed, and *member* is the natural term. If there is to be another grade, it should be for those who, already in business and on the proposed register, would submit to a modified examination, and accept a similar term—associate is a good one—but would renounce all claim to a share in the government of the Society.

Such are our own ideas of the subject. We offer them with every wish to see Pharmacy rank higher than it has yet done as the handmaid of Medicine.

It must be remembered that the statements in this article in nowise apply to Ireland, where for many years the practice of Pharmacy has been restricted by law to licensed apothecaries. No chemist or druggist can compound a prescription in Ireland.

## Notes on Current Topics.

THE NEW PHARMACOPEIA.—The delay in the production of this important national work has now ended. The book is in the hands of the Profession, and, for good or evil, will, probably, for some years, be the only recognised authority in the three kingdoms. The reception that has been accorded to it thus far is really encouraging. We have no

wish to be captious, no desire to look for defects, and we think all interested in the matter will be glad to be relieved from the uncertainty in which medicine and pharmacy have so long been involved. An enormous cost has been incurred by the Profession, and it is sincerely to be hoped that the new edition will prove as useful as that of 1864 proved useless. It is a well got up volume, in post 8vo, and the price has been fixed at 6s. We cannot but feel that this is rather too much. Long ago we urged the propriety of selling it at the usual price of Parliamentary blue books. It is almost too bad that those who, in good faith, purchased the more expensive volume in 1864 should, in 1867, be subjected to a fine for their endeavour to comply with the laws. It is, however, too late for further remonstrance, and we hope the present work will soon be generally used. We have already devoted several articles to a consideration of its contents, and now that it is actually in circulation, shall be obliged to recur to it more at length. It will be our endeavour to treat its provisions with the candour and impartiality which have characterised all our criticisms, and with the fullness that a work of such authority unequivocally demands. In the columns devoted to our correspondents we shall, of course, be as ready to express the opinions of others on this as on other topics. At the same time we may state that, in any discussion that may be provoked, we must attach the greatest importance to those communications that are the most practical. There has been sufficient display of fencing in reference to the numerous points on which differences of opinion prevail, and it is now time to take our Pharmacopœia as a standard, and disseminate as much information about it as possible.

**CHOLERA PROSPECTS.**—We have on several distinct occasions warned our readers against the forgetfulness of a possible return of the epidemic, and urged the necessity of continued vigilance. In London, one death has already appeared in the Registrar-General's report, as possibly arising from that disease. There is considerable doubt, in the absence of a post-mortem examination, what was the real cause of death, but there is no doubt whatever that diarrhoea was prevalent at that time in the neighbourhood. We should be very sorry to act as alarmists, but it is impossible to conceal the existence of certain indications that might serve as warnings to all in authority to take every precaution. In Russia we are aware that the epidemic can scarcely be said to have completely died out, for every now and then a fresh crop of cases has appeared. In St. Petersburg, Moscow, and other towns, several cases have recently occurred in succession, and may well excite suspicion. On the other hand, the news from Mecca is satisfactory, and, we trust, that place will not again become a focus of disease.

**THE MEDICAL COUNCIL.**—The first meeting of the Session is fixed to take place on the 29th, so that all petitions intended to be laid before this body should be forwarded immediately. In connection with this subject we may notice that a proposal has been made by the editor of the *Medical Mirror*, to secure the representation of the profession at large in the Council. It is argued that members elected by the whole body of the profession would afford some balance against the nominees of the Corporations and the Crown, but it is not easy to comprehend how the various discordant interests in the Council could be neutralised by the introduction of a new element, unless

a great numerical superiority be given to it. The Crown Nominees on the Council were placed there as the unprejudiced representatives of the public, and we cannot see that the clue to an adjustment of contending parties will be found in the raising up of new contentions.

**UNIVERSITY REPRESENTATION.**—We are glad to see that one of our contemporaries has adopted the view we have several times advocated respecting the Representation of the Universities. It is strange that at present the Government cannot be induced to go further in this direction than the offer of one Member to the London University. Should their present measure be carried it will be necessary to insist, in the strongest manner, on an equal justice being done to each of the unrepresented Scotch and Irish Universities, in the promised *Reform Bills* for those kingdoms.

**A MEDICAL TEACHER'S ASSOCIATION.**—The best method of educating students, the surest way of affording them every opportunity of becoming efficient practitioners, and many other points of the greatest interest to all who are or have been actually engaged in the great work of training young men for the responsible duties of our Profession, are all subjects on which a little intercommunion of teachers may be highly desirable. We are, therefore, glad to learn that an Association of the medical teachers in the London Schools is being formed for the purpose of discussing this matter in all its bearings. We cordially wish the Association success, and beg to add that a similar movement in each of the Provincial Schools might also furnish equally valuable suggestions. Suppose an independent Association of the teachers in each of the towns where there are Medical Schools to be called into existence, how easy it would be to arrange for a congress or other mode of union for joint discussion. This would be better than branches of the Metropolitan Association, because it would keep all local matters separate, and each society would be supreme in its district, and therefore command more respect. Teachers of Dublin, Edinburgh, Glasgow, Cork, Belfast, Birmingham, Liverpool, and all other Medical Schools, is it not worth your while at once to make this effort for union?

**A FRENCH VIEW OF THE CLITORIDECTOMY DISPUTE.**—The following translation from *La Médecine Contemporaine* has been sent us for publication:—"The English mind has such a spice of prudery—a timidity and a modesty so ready to take alarm, that words in most common use startle it, and spread a bashful blush over countenances the least susceptible of shame. Never in presence of an Englishman pronounce the word *drawers*; never give utterance to the word *chemise*—if you have to speak of the *thighs* or of the *breeches* which cover them, use a circumlocution, and indicate, without naming them, the things of which the utterance is so offensive. The ancients, in order to restrain the excessive incontinence of certain females, frequently amputated the clitoris; but that operation for more than a century seems to have been discontinued, and even formally rejected, although Robert had practised it with success, as to its physical and moral effects, upon a young girl reduced to imbecility by habits she could not overcome, and, notwithstanding the advice of P. Debreyne, who actively endeavoured to revive that ancient practice, in which he saw no danger, and found great advantages. That operation of Robert, an idea, it would seem, derived

from the Greeks, and that opinion of P. Debreyne, has produced scarcely any sensation in France. But in prudish England, Mr. B. Brown, a surgeon who owes his reputation to ovariotomy, performed also clitoridectomy when he considered it proper, that is, as often as Lisfranc cut the neck of the uterus. This was considered an abuse, and it was decided in the Obstetrical Society to make it a ground of accusation against Mr. Brown. All London was excited by the news. The journals resounded it, and publicly took part, some against, and others in favour of Mr. Brown. These last, in this important crisis, gave him open proof of esteem and sympathy. Yet he succumbed, and his colleagues in the Obstetrical Society voted his expulsion. This grave decision led Mr. Brown to resign his connection with the Medical Society of London. It is exceedingly difficult to know in this matter on which side justice lies, yet, if we may credit the grounds of condemnation, Mr. B. Brown carried his enthusiasm so far, as to dilate in public, the two sexes being present, upon the advantages of his operation."

**OMNIPOTENT QUACKERY.**—The advertisers of the quack nostrums of the old world are not slow to claim wonderful and diametrically opposed actions for their drugs, but they are eclipsed by their brethren of the new world, who save trouble and the expense of advertising a list of the diseases which their pills will cure, by laying claim to absolute omnipotence and infallibility. We extract the following amusing circular from an American journal:—

New Haven, Conn., February 27th, 1867.

Dear Sir,—My object in writing to you is to inform you of the Great Life Regulator.

It certainly is the greatest gift from Heaven to us as a people for the healing of our bodies. It instantly cures all forms of sickness, and in the shortest space of time heals the body from all diseases.

It is for this I take the pleasure of informing you of this great remedy, that you may become acquainted with a medicine which will in all cases, under all circumstances, be sure to give health to the sick.

Its accurate time in curing the sick in all cases, where they have not long been confined to their bed, is from one to eighteen hours.—Wishing you much happiness and health, M.D.

#### THE SANITARY CONDITION OF THE FEDERAL ARMY IN THE LATE CIVIL WAR.

THE fatigues and privations of a soldier's life in time of war, give him a full claim to the benevolence of the country whose interests he is armed to uphold. It is next to impossible to estimate the amount of evil to which he is exposed, arising from hard labour, sustained effort, weather, disease, fierce struggle, wounds, and lingering death. Considering he is put in that position, not for his own interest chiefly, but for that of the whole community, it becomes those who reap the benefit which he secures for them, to lighten those evils in every possible way they can. Generally speaking, in civilized countries there is no backwardness in performing such duty. The enthusiasm felt in a popular cause, awakens a sympathy with the actors and sufferers in the ranks, though often-times the crisis in which an army is brought into the field, and the ineffective military arrangements which were made, defeat, in a great measure, the efforts of those at home to provide for the necessities of the soldiers who are out fighting the battle for them.

Such was the case in America at the commencement of the late struggle between the North and South. The moment a call for troops was made, the philanthropists of New York called a meeting, and formed what was termed the "Women's Central Association of Relief." The object proposed was, in their own words, "to collect and disseminate information upon the actual and prospective wants of the army, establish recognised relations with the

medical staff, and act as auxiliary to it, and maintain a central depot of stores, and open a bureau for the examination and registration of nurses." Excellent as was the intention, the obstacles which stood in the way of its accomplishment were of no ordinary kind. The first regiments, apart from the regular army, which it was necessary largely to augment, were composed of the young men of the militia and volunteer companies who had never seen actual service, and were therefore less able to endure the efforts required of them, and more likely to suffer from the difficulties of the struggle to which they were committed. The officers, too, were ignorant, in a great measure, of the duties of their position; while the men, young, proud, unaccustomed to strict discipline, were reluctant to bow to those, higher in rank it is true, but almost as deficient in real military knowledge as themselves. There was, in consequence, no regularity, no steady order, no strict sanitary measures adopted, and there followed, as might have been expected, a state of things deplorable to behold. The conveyances which brought the men to the capital were cattle cars, crowded to excess, and with no means of relief for the sick. No provision was made for them on their arrival there. "For hours they stood broiling in the sun, or drenching in the rain," and when at last they reached their camps, unwholesome rations were served out to them, and rotten straw and a shoddy blanket provided as the only means of repose. No wonder that diseases common in camps, but which, if proper precautionary measures are taken, may be almost entirely banished, should threaten the destruction of nearly half those unhappy volunteers.

It was on this emergency that the Association began its labours. Its members naturally expected that the medical department of the army would encourage their efforts, but they were almost immediately destined to disappointment. They were considered by the officers of the Medical Staff to be unnecessarily intruding into a sphere where their assistance would be of little or no value; and representations were made to Dr. Bellows, under whose directions the Association was organised, and who was their delegate at New York, which induced him to return with the conviction that "ample preparations were already made." The ladies, however, true to their nature and their instincts, were not thus to be defeated and turned aside from their labour of love. They began to prepare lint for dressing wounds, to choose women and train them for nurses, and soon decided on making another effort to gain the notice and sympathy of the authorities. Four gentlemen were accordingly sent to Washington, who succeeded in obtaining an interview with General Scott, and next with the head of the Medical Bureau. The same coldness and indifference to their object was manifested—and they then proposed a mixed Sanitary Commission, but all to no purpose—they could not be heard. They had, however, made themselves felt in high quarters; and it was not long before the Acting Surgeon-General recommended the appointment of five gentlemen, including two of their number "to enquire and advise on sanitary points." The Government at length consented; but their full action, as a commission, was delayed by the opposition of a new Surgeon-General. Subsequently, they had sufficient influence to request his dismissal, which was complied with by the authorities, when a candidate supported by themselves was advanced to the post, and the object of all their earnest desires attained.

After this, the course of the Commissioners was plain and unopposed. Government had given them its sanction. Like earnest men they began to perform the work of humanity they had undertaken. "Two general committees were soon appointed—one for inquiry, the other for advice;" and the disclosures, resulting from their investigation, unveiled the wretched and pitiable condition of men with no effective military discipline. No one to provide for those exigencies on which their health mainly depended. No drains in their overcrowded camps. No clearance of the disgusting effluvia from the sinks. No free air, but an infected atmosphere surrounding them all the night. No proper clothing. No regard to personal cleanliness. No green vegetable supplied, and a consequent amount of scurvy

which threatened to decimate the whole effective force. Close upon this came the battle at Bull's Run, and no wonder that men in this state of degeneracy should be totally vanquished by a force far less numerous than their own. Inquiry was again set on foot by the Commission immediately after this disastrous defeat. Various questions were put both to officers and men who had been engaged in the fight. Information was carefully collated, and a fearful revelation—which it was judged proper to refrain from publishing at the time—was brought to light. A short quotation from a subsequent report will give an insight into its nature. At Washington, after the battle, it is said:—

"The appearance of the streets was in the strongest possible contrast to that which could be imagined of a city placed by a strong necessity under the severe control of an effective military discipline. Groups of men, wearing parts of military uniforms, and some of them with muskets, were indeed to be seen; but upon second sight they did not appear to be soldiers. Rather they were a most woe-begone rabble, which had, perhaps, clothed itself with the garments of dead soldiers left on a hard-fought battlefield. No two were dressed completely alike; some were without caps, others without coats, others without shoes. All were alike excessively dirty, unshaven, unkempt, and dank with dew. The groups were formed round fires made in the streets of boards wrenched from citizens' fences. Some were still asleep at full length in the gutters and on door-steps, or sitting on the kerbstone, resting their heads against the lamp-posts. Others were evidently begging for food at house doors. Some appeared ferocious, others only sick and dejected, all excessively weak, hungry, and selfish. There was no apparent organisation; no officers were seen among them; seldom even a non-commissioned officer. At Willard's Hotel, however, officers swarmed. They, too, were dirty and in ill condition; but appeared indifferent, reckless, and shameless, rather than dejected and morose."

Military Hospitals were provided by the Commission for the large crowds of sick and wounded men. Buildings had been hastily appropriated for this object, but utterly inadequate to the necessities of the case; while the attendants, the nurses, and the staff were not equal to the task they had to perform. Further accommodation was, therefore, absolutely necessary, and the importance of the efforts made by the Commission in this direction, was so sensibly felt, that the Government gave them its decided support. "Five model buildings" were erected, where army patients have been received and attended during the whole of the war. By their means, also, a service of transport boats conveyed the sick and wounded to the general hospitals, and railway cars were fitted up with litter beds swung in each, besides a broad couch and invalid chairs, with medicine, utensils, food, indeed every article furnished which would contribute to the comfort and well-being of the patient, however unfavourable the weather, or long the journey. Depots of hospital stores and drugs were fixed near the seat of war, and every relief possible afforded to the bodily or mental anguish of the sufferer. The medical authorities, too, began to appreciate the services of these men, and to work harmoniously with them, and when their waggons appeared on the battle-field, inscribed "U. S. San. Com.," even surgeons were heard to exclaim "Thank God, here comes the Sanitary Commission; now we shall be able to do something."

By such means, and others as well, these devoted and noble-minded men endeavoured to relieve the pain and sustain the courage of the wounded and the diseased. No adequate preparation had been made by the Government, and but for their voluntary and untiring devotion no one can tell how much the amount of suffering would have been increased, or how many more would have died miserably in the field during those years of internecine war.

#### QUARTERLY RETURN OF THE REGISTRAR-GENERAL.

LITTLE or no relative difference is found in the figures and facts of the Registrar-General, as we trace his quarterly

steps from time to time, and listen to his warnings or his congratulations, as the balance of the death-rate vibrates upwards or downwards. In ordinary seasons we look for the estimated number of figures, and we generally find them. When severe weather has intervened or some epidemic laid its fell grasp upon the terrified population, marking out first one locality and then another for its fearful intrusion, we are prepared to hear that the "mourners have gone about the streets" in far larger proportions, and so the report invariably shows it to have been. Even commercial prosperity or abatement leads us to expect some variation in the numbers to be recorded, and almost always our anticipations are found to be correct. There is little or no interest therefore in following his figures for their own sake, just to see how many have died one season more or less than another, or how the marriages and births rose or sunk; but still his returns are important, and it is well they should be regularly exposed to our view. Otherwise, we might remain ignorant, or grow careless of threatening dangers, and consequently neglect the means necessary for self-preservation and health.

From his report of the last quarter, it appears that the general health in England and Wales has been in a better state than in the same quarter of the last three years. In the winter quarter of 1864 the deaths were 142,977; in 1865, 140,410; in 1866, 138,233; and in the present year 134,254. Indeed, taking the indication from the marriages and births as well it would seem that the public health has been really improving during those years. The fact which has swelled the death-rate in 1866, is the prevalence of cholera. But for this it would have steadily decreased all that time.

During the quarter whooping-cough, small-pox, and measles, which are principally children's diseases, have been most prevalent, but, in some places, the old and infirm have suffered severely from the cold, and the mortality among that class has been great, which is not to be wondered at, considering the abrupt and unusual variation of the temperature.

The annual rate of mortality in the whole kingdom for the winter quarter was 26 per 1000—it was 27 for the town, and 23 for the country districts generally. But the returns, though favourable on the whole, show that mortality has varied in different districts. It has been least in the Eastern counties, particularly in Yarmouth and Norwich; very little more in the South-Eastern, but largest in the South-Midland. In the thirteen large towns in the kingdom it has also varied considerably. In London it was 26·78 per 1000; in Newcastle, 37·10; in Dublin it was 34·62; in Manchester, 33·81; in Glasgow and Liverpool, slightly less; in Bristol, 25·50; in Birmingham, 25·35; in Hull 25·23. The difference of position and climate seems not enough to account for this discrepancy in the death-rate of these several towns, and it is a question worthy of consideration whether it may not be traced to the habits of the people, to the care which some of them take, and the indifference manifested by others to those sanitary regulations which are necessary to secure immunity from the attacks of consequent ravages of disease.

### Proceedings of Societies.

HARVEIAN SOCIETY OF LONDON.—APRIL 10.

Dr. POLLOCK, President.

THE PREVENTION OF VENEREAL DISEASES.

PRESENT—Dr. Chapman, Mr. Curgenvin, Dr. C. Drysdale, Mr. Gascoyen, Dr. Tilbury Fox, Mr. James Lane, Dr. Meredyth, Dr. Menzies, Mr. Sedgwick, Mr. De Meric, Mr. Holmes Coote, Mr. R. W. Dunn, Dr. Victor Bazire, Dr. A. Vintras, and Mr. Berkeley Hill.

The following reports were read:—

Dr. Steele reports from Guy's Hospital, that in 1866 there were at Guy's Hospital, 36,600 ordinary surgical cases; 2500 disease of the eyes; 700 of the ear; 700 of the skin. Of the surgical cases it is stated that nearly 24,000, or two-thirds, of the surgical cases are venereal. Among medical cases the

venereal cases are estimated at about 5 per cent.; among diseases of the eyes about 10 per cent.; and of the ear about 5 per cent.; among disease of the skin about four-fifths of the cases are said to be venereal. Among female diseases above 10 per cent. are said to be venereal. Dr. Steele calculates that there are about 26,000 venereal cases annually seen at Guy's Hospital, or about 43 per cent. of all cases seen. There are 55 beds for venereal patients—25 for males and 30 for females, and about 50 occupants of these beds daily.

Mr. Hill's report from the Royal Free Hospital, Gray's Inn Road, gives the daily number of venereal patients treated at that Hospital as 117.2. This number is in the proportion of 3.8 to the number of surgical patients seen daily. There are 26 beds for female lock patients; the males are only admitted when the cases are urgent, and are then placed in the ordinary surgical wards. On an average, about two of such beds are occupied by men.

Dr. Gillespie's report from the Lock Wards of the Royal Infirmary, Edinburgh, gives an average of 20 cases daily treated, which is in the proportion of 1.8 of the whole surgical patients in the Infirmary. There are 26 beds for venereal patients in the Hospital. "Occasionally stray cases of primary venereal diseases are treated in the general surgical wards, and secondary and tertiary cases are constantly admitted by the physician into the general wards."

The report from the Royal Infirmary of Glasgow shows a daily average of 20 venereal cases treated, or 1 in 12 of the whole surgical cases treated. There are no special beds for lock cases.

In the report from Dr. McLeod, from the Glasgow Lock Hospital, it appears that there are 38 in-patients—no out-patients in that hospital—on an average. There are 45 beds in that hospital.

In the report by Mr. Newett, from the General Hospital, Belfast, it appears that the average number of venereal in-patients is 6. There are no venereal out-patients. This number is, to the whole daily number of surgical patients seen, as 1 : 17.5. No beds are specially set apart for male patients. There is a small ward for females.

In the report by Mr. Chance, from the Metropolitan Free Hospital, Devonshire-square, London, it is stated that there is an average daily attendance of 280 out-patients, and Mr. Chance estimates the number of venereal cases among these as about one-third. There are no in-patients lock cases.

The report by Mr. Mickley, from Nottingham General Hospital, gives a daily average of nine venereal cases, in and out-patients, or about one-fifteenth of all the surgical cases seen. There are eight beds for such cases: never all occupied at once. "Most of the cases that do come are cases of secondary syphilis. Primary sores and cases of gonorrhoea, are very seldom seen. A certain class of practitioners and the quacks get hold of them all."

The report from the North Stafford Hospital shows nine in and eight out-patients daily, in the proportion of 1.32 to the whole number of surgical cases seen.

The report from the Hull General Infirmary shows a daily average of 14 venereal patients, or one-seventh of the surgical cases seen. There are no venereal beds in the hospital.

In Dumfries, according to Dr. Watson, there are scarcely any venereal patients—only one in eight days; and there are no beds for venereal patients in that hospital.

In the Herbert Hospital, Woolwich, the report from Surgeon-Major Dr. Guy gives the daily average of in and out-patients as 84. All venereal cases in the army are treated in hospital. In the ordinary surgical non-venereal wards the average number under treatment is 53. There are three lock wards, each containing 32 beds, for treatment of venereal disease, and as many additional beds as are required can be added.

Dr. Menzies reports from the Western General Dispensary, Paddington, that the proportion of venereal cases to the surgical cases daily seen is as 1:10. A few cases of the sequelæ of syphilis are occasionally seen by the physicians, but not in sufficient numbers sensibly to alter the above ratio.

The following statistics of prostitution were furnished to the committee by Mr. Gascoyen, from the blue-book entitled "Judicial Statistics for 1865." The total number of prostitutes in England and Wales in September, 1865, was 27,548, and the total number of brothels and houses of ill-fame was 6949, out of a total population of 20,990,946, of which 10,180,820 were males, and 10,810,125 were females. In London, according to the same statistics, there were in September, 1865, 5911 prostitutes, and 1193 brothels and houses of ill-fame, out of a population of probably more than 3,000,000. In 1861 the population of London was 2,803,989.

Mr. JAMES LANE thought that it would be better in future for the committee to concentrate their attention upon the quantity of venereal disease in two or three towns, such as London, and perhaps a seaport and inland town.

Mr. GASCOYEN remarked that in country districts there was scarcely any venereal disease. It was in the large towns that it was so frequent.

It was resolved that the secretary should communicate with the medical men in London, Manchester, Southampton, Salisbury, and Norwich, and endeavour to get at the extent of venereal diseases in these four typical cities.

Mr. DE MERIC suggested that some private practitioners should be asked as to the numbers of their venereal patients yearly.

Mr. Coote and other gentlemen believed that this would be a difficult matter to perform, and that the results would not prove trustworthy.

Mr. DE MERIC wished to know whether the committee intended to cause and enforce examinations and detention in hospital of all diseased women. At present they leave hospital when they think fit, even when diseased. Were they to be kept in, again, until even the slightest amount of purulent discharge was gone?

Mr. JAMES LANE thought that they should not be allowed to quit hospital till perfectly well, and that examinations should be enforced.

Mr. HOLMES COOTE thought that, to be of any use, stay in hospital must be rendered compulsory until the patients were cured, as they at present were in the habit of leaving whenever any festive occasion occurred, as at Christmas, &c.

Mr. BERKELEY HILL said that small-pox and fevers were separated from the rest of the community, and there was no reason why this should not be done in the case of venereal diseases.

Mr. DUNN also agreed that examinations ought to be made compulsory.

Dr. CHAPMAN thought that the Government had a perfect right to pass any measure it pleased to protect its own paid servants in the Army and Navy; but he maintained that in civil life that society had not a similar right over the persons of women who prostituted themselves. As long as they were treated with such contumely at hospitals, as they were now, it was natural they should not care about entering them, or remaining in them; but if they were treated with kindness, and forced to sign a written agreement to remain in until cured, he thought this would serve instead of forcible measures. He therefore proposed the following motion:—

"This committee deploras the great and increasing amount of venereal disease in this country, and recognises the urgent need of an ample provision for its efficient treatment; but, while admitting the right of the State to protect its paid servants—the Army and Navy—from the influence of the venereal contagion, by the adoption of any measures which shall seem to it best, this committee would view with grave apprehension the application of the 'Contagious Disease Act' to prostitutes generally, or any attempt to 'protect' the general population by submitting to registration and compulsory medical supervision the large class of women throughout the country who are known, or supposed to be, acting as prostitutes."

Dr. C. DRYSDALE said that there were so many points in the motion made by Dr. Chapman in which he agreed, that he would second it if only to hear the subject discussed. He thought that the registration and police control of women was in many respects very undesirable, since it treated that sex as if they were to be suffered to be in perpetual nonage. And although he was well aware (and had stated the same fully in a pamphlet he had published on the subject) that this registration and forcible examination had very much lessened the prevalence and extent of venereal diseases in France, Belgium, Norway, and other Continental states, still the very fact of the French having proposed this as a subject for discussion at the ensuing International Congress in Paris, in August, showed how many deficiencies there were in the system of police interference. For his own part, he believed that the main cause of the extreme prevalence of the venereal diseases in our large cities was to be traced to the way in which prostitutes were treated at hospitals and public institutions. In many hospitals there were no beds for them, and in almost all they were treated with much harshness, so that there was little wonder that they stayed as little time as possible in the wards, and that they cared also little for the fate of others. The true Christian spirit would point towards alleviating the evils of prostitution

so long as that frightful evil existed, and not stamping the women with a police badge, as was done in Foreign States, where ideas of individual liberty were certainly less enlightened than in England or America.

Mr. HOLMES COOTE said that if this motion was carried, he believed that nothing could be done by the Committee. There was plenty of provision for women in garrison towns, yet they went out whenever they pleased, even when diseased, and so in St. Bartholomew's Hospital the beds were often empty at Christmas, and whenever the occupants thought that they could get plenty of customers.

Mr. CURGENVEN spoke in favour of registration.

Dr. VINTRAS said that it was necessary to compel prostitutes to be examined. No voluntary system would succeed with them, and in Paris it was found that they never showed their certificate of examination, but carefully concealed it. One difficult point was the definition of the word *prostitute*.

Mr. SEDGWICK said that the liberty of the subject had often been attacked for the public good, as in the case of overcrowding of the poor in large towns, and in cases of Vaccination Acts, etc., certain houses in poor districts were liable to be entered at all hours by the police to prevent overcrowding, etc.

Dr. BAZIRE thought that unless women were compelled to be examined they would not come. In hospitals where there were many students they also would not come.

Dr. CHAPMAN's motion was then put to the meeting, but lost; there being a majority of fifteen members against it to two for it.

Mr. JAMES LANE said that he would move the following motion as an amendment. He did so because he believed that any voluntary system would prove inoperative, and he thought that the public might be prepared for a compulsory system, as a question of hygiene. Compulsory examination of the healthy as well as diseased prostitutes should be carried out, and there should be no certificate of health given to the woman herself.

The following amendment was moved by Mr. JAMES LANE, and seconded by Dr. TILBURY FOX:—

"That regulations similar to those contained in the Contagious Diseases' Prevention Act, 1866, might be carried out by the police, without difficulty, among the civil population in London and other large towns, the essential feature of the system being as follows:—

"That a register of all women known to be acting as prostitutes should be kept by the police. That such women should be required to submit themselves to a periodical examination by a medical officer, appointed for that purpose, and that, when found to be suffering from venereal disease, they should be detained in hospital till cured—additional accommodation being provided for that purpose.

"It is desirable that the registration of women above suggested should be kept for the private use of the police authorities only, and should be in no way accessible to the public; also, that no certificate of health should be given to the women on the occasion of their periodical examinations, and that, when discharged from hospital, the certificate of cure should not be given to the women themselves, but be forwarded to the police authorities.

"The object of legislative interference should be solely the prevention and cure of venereal disease; and it is believed that this desirable end would be, to a great extent, obtained by regulations such as those above suggested, which would be sanitary in their operation, and which would involve no public recognition of prostitution, and no registration of prostitutes or of houses used for the purpose of prostitution that would be available to the public."

This amendment was put to the meeting by the President, when fifteen members held up their hands in favour of it, and only two against it. It was therefore declared to be carried. The business of the next meeting will, therefore, be to consider the details of the question relating to the police registration and examination of prostitutes, and to receive reports from London, Southampton, Norwich, Salisbury, and Manchester.

#### BELFAST BRANCH OF THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

The stated quarterly meeting of this local branch of the above most excellent and useful society was held on the 1st inst., in No. 33, High-street, and amongst those present were—Dr. T. H. Purdon, the permanent president of this branch, who occupied the chair; Dr. Patterson, Dr. Ferguson, Dr. James

Moore, Professor Cuming, M.D.; Dr. Keown, R.N.; Dr. Whitaker, Dr. Willberforce Arnold, Dr. Filson, Portaferry; and Dr. Stewart, honorary secretary.

A letter was read from Dr. E. G. Grattan Guinness, honorary general secretary, Dublin, calling attention to the annual meeting of the society, to be held next month in the Royal College of Surgeons, for the distribution of funds and the transaction of general business, and requesting a *resume* of the proceedings of this branch for the past year as usually supplied, and which was directed to be furnished accordingly.

After the reading and disposal of several other communications, the consideration of applications for assistance from those belonging to the Counties of Antrim and Down was proceeded with; and each case having been particularly inquired into and found to be a proper object for relief, all as presented were passed, and recommended to the Parent Society for grants as liberal as the funds at command would admit of and the necessity of each appeared to demand. The report of the contributions of this branch to the present time was more favourable than as compared with the corresponding period last year; but the subscriptions of several being still unpaid, it was earnestly requested that they would be sent in as immediately as possible; and Dr. Moore's service as a deputation to country localities on behalf of the society, hitherto so successful, were asked again on the present occasion, and kindly acceded to. It was also agreed upon that the Secretary should make special application to those Members of the Profession who had not hitherto afforded any assistance to the Society, soliciting their aid, even in the smallest sums, the Society's usefulness in giving efficient relief chiefly arising from what was received by annual subscriptions. The following subscriptions were reported to have been recently received:—Rev. William O'Neil, Shane's Castle, per Dr. Spearing, £12; Dr. Stephenson, £5; Dr. T. Reade, £1 ls.; Dr. Filson, £1 ls.; Dr. Wheeler, £1 ls.; Dr. Scott, 4th Battalion Rifle Brigade, £1; Dr. McClelland, Banbridge (for 1866), 10s. 6d.; Mr. Strain, Newtownards, 10s.; Mr. Pring, 10s.; Surgeon Smyth, 10s. 6d.; Dr. Warwick, 5s.; Dr. Murland, 5s.; Dr. Heron, Katesbridge, 5s.; Surgeon Harman, Ballyward, 5s.; Mrs. McClelland, Rathfriland, 5s.; Dr. May, do., 5s.; Thomas Ferguson, Esq., Banbridge, per Dr. Malcomson, £1 ls.; Dr. Rowan, per do., 10s.; Dr. Malcomson, 10s. Some further business having been disposed of, thanks were given to the chairman, Dr. T. H. Purdon, for his great readiness and liberality on behalf of the best interests of the society, and the meeting separated.

#### METROPOLITAN POOR ACT, 1867.

As this important measure; if found to work well in London, is likely to be extended to the rest of the Kingdom, we furnish a complete abstract of its provisions.

1. This Act may be cited as the Metropolitan Poor Act, 1867.
2. Limits the Act to the Metropolitan.
3. Limits orders of Poor-law Board.

#### DISTRICT ASYLUMS.

5. Asylums to be supported and managed according to the Provisions of this Act may be provided under this Act for Reception and Relief of the Sick, Insane, or Infirm, or other Class or Classes of the Poor chargeable in Unions and Parishes in the Metropolitan (and in this Act the Term "Asylum" means an Asylum provided under this Act).
6. In order to the Provision of Asylums, the Poor-law Board may from Time to Time by Order combine into Districts, Unions or Parishes, or Unions and Parishes, in the Metropolitan, as they think fit, and may from Time to Time alter any such District by Addition, Sub-division, Separation of Part or otherwise (and in this Act the Term "the District" means, in relation to each Asylum, the District for which that Asylum is for the Time being provided).
7. For each District there shall be an Asylum or Asylums, as the Poor-law Board from Time to Time by Order direct.
8. Incorporates the managers of Asylums.
9. The Managers shall be partly elective and partly nominated.
10. Elective Managers shall be from Time to Time elected by the Guardians of each of the several Unions and Parishes forming the District from among themselves, or from among Ratepayers qualified to be Guardians therein, or partly from one and partly from the other.

11. Nominated Managers shall be from Time to Time nominated by the Poor-law Board from among Justices of the Peace for any County or Place resident in the District, or from among Ratepayers resident in the District and assessed to the Poor Rate therein on an annual rateable Value of not less than Forty Pounds, or partly from one and partly from the other.

12. The Poor-law Board shall from Time to Time by Order prescribe the total Number of the Managers, and the Proportion of the Elective and Nominated Managers, (but so that the prescribed Number of the Nominated Managers do not ever exceed One Third of the prescribed Number of the Elective Managers), the Number of Elective Managers to be elected for each Union or Parish in the District, the Qualifications of the Managers, their Tenure of Office, the Mode and Times of Election, and the Quorum for their Meetings.

13. Provides for the Validity of Acts of Managers notwithstanding Vacancies.

14. Prohibits Managers being concerned in Contracts.

15. The Poor-law Board may from Time to Time by Order direct the Managers to purchase or hire, or to build, and (in either Case) to fit up a Building or Buildings for the Asylum, of such Nature and Size, and according to such Plan, and in such Manner, as the Poor-law Board think fit, and the Managers shall carry such Directions into execution.

16. The Managers shall have for the Purposes of the Asylum the like Powers as are for the Time being vested in Guardians of Unions or Parishes in the Metropolis relative to the Purchase or Hiring of Lands or Buildings; but the Consent of any Ratepayers or Owners of Property in a Union or Parish shall not be necessary with respect to any Sale, Lease, or other Disposition of any Workhouse, Building, or Land by Guardians or Overseers to the Managers.

17. The Managers may borrow Money for purchasing Lands or Buildings, and for building, fitting up, and furnishing Buildings erected or hired for the Asylum, according to the Provisions of the Poor-law Acts under which Guardians are for the Time being empowered to borrow Money, and may charge the Poor Rates of the Unions and Parishes forming the District with the money so borrowed, and Interest, subject and according to the following Provisions:

- (1). The Amount borrowed shall not exceed One Third of the aggregate annual Expenditure on the Relief of the Poor within the whole District (exclusive of Reimbursements) for the Period of Three Years ending on the Twenty-fifth Day of *March* next preceding the borrowing of the Money;
- (2). The Amount borrowed shall be charged on the Poor Rates of the several Unions and Parishes forming the District in the Proportions in which they contribute to the Maintenance of the Asylum;
- (3). The Amount borrowed shall be paid off, with Interest, by equal annual Instalments not exceeding Twenty.

18. The Poor-law Board may by Order direct that any Building for the Time being in use as a Workhouse be, with such Alterations as the Poor-law Board think fit, used for the Asylum, and thenceforth that Building shall be for the common Use of the District accordingly; and an annual Sum in the nature of Rent or other Compensation of such Amount as the Poor-law Board from Time to Time direct shall be paid to the Guardians of the Union or Parish to which such Building belongs, as long as the same continues to be so used.

19. Secures reimbursement to Managers of Expenditure.

20. Relates to Furniture, &c., for Asylum.

21. The Mode of Admission of Persons into the Asylum shall be such as the Poor Law Board from Time to Time by Order direct.

22. The Managers shall have the like Powers as Guardians for the Relief, Maintenance, and Management of the Inmates of the Asylum, and shall from Time to Time provide such Medicines, Appliances, and Requisites for the Medical and Surgical Care and Treatment of the Inmates, and cause the same to be furnished and used according to such Rules, as the Poor Law Board from Time to Time by Order direct.

23. The following Provisions of the Poor Law Amendment Act of 1844 shall extend to the Asylum as if it were an Asylum under that Act or a Workhouse, and as if the Managers were a District Board under that Act, that is to say,—

So much of Section Forty-three as relates to Rules of the Poor Law Board for Government of the Asylum or its Inmates, and to religious Assistance and Instruction: Sections Fifty, Fifty-four, Fifty-seven, and Fifty-nine.

24. With reference to Chargeability, Burial, and other In-

cidents, the Asylum shall in relation to each Inmate thereof be deemed to be in the Union or Parish from which such Inmate is sent; but Births and Deaths in the Asylum shall be registered by the Registrar in whose District the Asylum is situate.

25. The Managers shall have the like Powers as Guardians for the Appointment, Control, and Payment of paid Officers of the Asylum, and the Grant of Superannuation Allowances to them.

The Duties, Number, and Salaries of the paid Officers, and the Securities to be given by them, shall be such as the Poor Law Board may from Time to Time approve or by Order direct.

26. Legal and reasonable Orders of the Managers shall be obeyed, and Obedience thereto shall be enforced, in like Manner and by and under like Remedies and Penalties as legal and reasonable Orders of Guardians.

27. The Managers may from Time to Time, subject and according to such Regulations as the Poor Law Board from Time to Time by Order prescribe, appoint Committees of Members of their Body, and delegate to them any of the Powers of the Managers.

28. The Managers shall, in the Exercise and Discharge of all their Powers and Duties, be subject to Orders of the Poor Law Board in like Manner as Guardians are under the Poor Law Acts.

29. Where the Asylum is provided for Reception and Relief of the Sick or Insane it may be used for Purposes of Medical Instruction, and for the training of Nurses, in such Cases and Manner and subject to such Regulations as the Poor Law Board from Time to Time by Order direct.

30. Where the Asylum is provided for Reception and Relief of the Insane the Commissioners in Lunacy may, if they think fit, depute one of their Body or appoint from Time to Time a special Commissioner, and the Person so deputed or appointed shall be entitled to attend Meetings of the Managers and to take part in their Proceedings, but not to vote; and every such Asylum shall be considered as a Workhouse within the Meaning of the Lunacy Acts as defined by the Twenty-fifth and Twenty-sixth *Victoria*, Chapter One hundred and eleven.

31. Expenses of providing Asylum and Salaries.

32. Charges for Maintenance, &c.

33 to 37 provide for audit of accounts, &c.

#### MEDICAL OUT-DOOR RELIEF.

38. The Poor-law Board may from Time to Time, by Order, direct the Guardians of a Union or Parish in the Metropolis to provide a Dispensary or Dispensaries for such Union or Parish, and to purchase or hire, or to build, and (in either case) to fit up and furnish a Building or Buildings for that Purpose, of such Nature and Size, and according to such Plan, and in such manner, as the Poor-law Board think fit, or to set apart, adapt, fit up and furnish for that Purpose such Part of the Workhouse of the Union or Parish, according to such Plans, and in such Manner, as the Poor-law Board think fit, and the Guardians shall act accordingly; and, where the Poor-law Board by Order so direct, the Guardians may borrow the Amount requisite in that Behalf, in like Manner and subject to the like Conditions as in the Case of the building of a Workhouse.

39. There shall be a Committee of Management for the Dispensary or Dispensaries in each Union or Parish, to be called the Dispensary Committee for the Union or Parish (and in this Act the Term "the Dispensary Committee" means, in relation to each Union Parish, the Dispensary Committee for the same for the Time being).

40. The Dispensary Committee shall be elected by the Guardians of the Union or Parish from among themselves, or from among Ratepayers of the Union or Parish, assessed to the Poor Rate on an annual rateable Value of not less than Forty Pounds, or partly from one and partly from the other.

41. The Poor-law Board shall from Time to Time prescribe with respect to each Committee the Number and Tenure of Office of the Members, the Mode and Times of Election, and the Quorum for their Meetings.

42. The Guardians of each Union or Parish providing a Dispensary shall also provide, according to the Directions of the Poor-law Board, proper places where the Medical Officers of the Union or Parish may see such of the Sick Poor as attend there for Advice, and where Meetings of the Dispensary Committee may be held.

43. The Dispensary Committee shall from Time to Time appoint and shall at all Times keep appointed proper Persons to be Dispensers of Medicine at the Dispensaries for the Union or Parish, and may from Time to Time appoint such

other Officers and such Servants for the Purposes of those Dispensaries as they think fit.

The Duties, Qualifications, Number, and Salaries of the Dispensers, Officers, and Servants shall be such as the Poor-law Board may from Time to Time approve or by Order direct.

44. The Guardians of each Union or Parish providing a Dispensary shall from Time to Time, on the Requisition of the Dispensary Committee, provide proper Medicines and Appliances and Requisites for the Care and Surgical Treatment of the Sick Poor of the Union or Parish relieved out of the Workhouse, and the same shall be dispensed and furnished to such of the Poor entitled to Relief as require the same, on the Prescription or written direction of the District Medical Officer, subject to such Regulations as the Poor-law Board from Time to Time by Order direct.

45. The District Medical Officers for a Union or Parish shall be from Time to Time appointed by the Dispensary Committee, subject to the Rules and Orders of the Poor Law Board respecting Appointment and Removal of Officers under the Poor Law Acts; but the District Medical Officers in Office at the Time of the Dispensary Committee entering on their Duties shall continue in Office as if this Act had not been passed, subject nevertheless to such Modifications of Arrangements respecting their Duties and Remuneration, made with them before the passing of this act, as the Poor Law Board think fit.

46. For giving Effect to the Provisions of this Act relating to Medical Relief out of the Workhouse, the Poor Law Board may from Time to Time vary as they think fit Medical Districts, Salaries, and Contracts with District Medical Officers, existing at the passing of this Act or at any time thereafter.

47, 48, and 49 provide for District and Separate Schools.

#### WORKHOUSES FOR CLASSES OF POOR.

50. Where, in the Opinion of the Poor Law Board, the Workhouse of a Union or Parish in the Metropolis is adapted only for the Reception of Poor Persons of a particular Class or particular Classes, but is capable of accommodating poor Persons of that Class or those Classes from any other Union or Parish within the Metropolis, the Poor Law Board may by Order direct the Guardians of the Union or Parish to which the Workhouse belongs to receive, lodge, and maintain therein poor Persons of that Class or those Classes, or any of them, and the Guardians shall receive, lodge, and maintain such poor Persons accordingly on terms to be agreed on, with the Approval of the Poor Law Board, by the respective Boards of Guardians of the Unions or Parishes concerned, or, in default of such Agreement, to be prescribed by the Poor Law Board by Order; and in every such Case the following Provisions shall have effect:—

- (1.) Every poor Person so received into the Workhouse shall, while therein, be treated in all respects in like Manner, and be subject to the same or the like Regulations and Liabilities, as the other poor Persons therein, and shall be chargeable in the first instance to the Union or to the Parish in the Workhouse whereof he is received:
- (2.) The abiding of any such poor Person in such Workhouse shall in all other respects be attended with the same legal Consequences as if the Workhouse were situate within the Union or Parish from which he is sent:
- (3.) Every Guardian of the Union or Parish from which such poor Person is sent may at all reasonable Times enter the Workhouse and inspect any part thereof.

51 to 54 refer to Purchase and Management of Lands.

55 to 58 Regulate the Contributions of Unions and Parishes.

#### MEDICAL IN-DOOR RELIEF.

59. In order to facilitate Provision for the Appointment, where requisite, of Resident Workhouse Medical Officers, and for better Classification and Management of the Sick Poor in a separate Hospital or Building, or in an Infirmary kept distinct from the rest of the Workhouse, the Poor Law Board may, by Order, determine, or from Time to Time vary as they think fit, any Contract with any Medical or other Workhouse Officer existing at the passing of this Act, and direct the Guardians to pay to a Medical or other Officer affected thereby such Compensation by way of increased Salary, or of an Annuity, or of a gross Sum, or otherwise, as the Poor Law Board think fit.

#### HOUSELESS POOR.

60. Sections One and Two of The Metropolitan Houseless Poor Act, 1864, shall from and after the Twenty-ninth Day of

September, One thousand eight hundred and sixty-seven be repealed, except with respect to any Claims under that Act then outstanding, which shall be provided for as if that Act continued wholly in force.

#### METROPOLITAN COMMON POOR FUND.

61. There shall be a Fund, called The Metropolitan Common Poor Fund, raised according to the Provisions of this Act by Contributions from the several Unions, Parishes, and Places in the Metropolis (in this Act referred to as the Common Poor Fund).

62 to 68 Regulate Appointment of Receiver, the Collection and Disposal of the Common Fund.

69. Expenses incurred for the following Purposes after the Twenty-ninth Day of September One thousand eight hundred and sixty-seven shall be repaid out of the Common Poor Fund, that is to say,—

- (1.) For the Maintenance of Lunatics in Asylums, registered Hospitals, and licensed Houses, and of Insane Poor in Asylums under this Act, except such Expenses as are chargeable on the County Rate:
- (2.) For the Maintenance of Patients in any Asylum specially provided under this Act for Patients suffering from Fever or Smallpox:
- (3.) For all Medicine and medical and surgical Appliances supplied to the Poor in receipt of Relief by Guardians under this Act or any of the Poor Law Acts:
- (4.) For the Salaries of all Officers employed by the Guardians in and about the Relief of the Poor by the Managers of District Schools under "The Poor Law Amendment Act, 1844," and by the Managers of Asylums under this Act, and also the Salaries of the Dispensers and other Persons employed in Dispensaries under this Act, provided the Appointments of the Officers have been sanctioned by the Poor Law Board:
- (5.) For Compensation to any Medical Officer of a Workhouse affected by the Determination or Variation by the Poor Law Board of a Contract respecting medical Relief in the Workhouse, or for Compensation to any Officer of a Union or Parish who may be deprived of his Office by reason of the Operation of this Act:
- (6.) For Fees for Registration of Births and Deaths:
- (7.) For Fees for and other Expenses of Vaccination:
- (8.) For Maintenance of Pauper Children in District, Separate, Certificated, and Licensed Schools:
- (9.) For Relief of destitute Persons certified by the Auditor, and Provision of temporary Wards or other Places of Reception approved by the Poor Law Board, under the Metropolitan Houseless Poor Acts of 1864 and 1865.

70 to 72. Mode of Repayment out of Common Fund; Receiver's Salary, and Drawing on Receiver's Account.

73 to 82. Define the Constitution of Guardians for Parishes under Local Acts; the Powers of new Board of Guardians; the Transfer of Property to new Guardians; the Continuance of existing Officers; the Saving for rating Powers of existing Bodies. Power to Poor Law Board to nominate additional Guardians. Appointment of Officers on Failure of Managers, &c. Extension of Borrowing Powers, to any Sum not exceeding One Half of the aggregate Amount of the Rates raised for the Relief of the Poor in that Union or Parish within Three Years next preceding. Provision for Orders of Removal and of Maintenance.

## Correspondence.

"BLACK DEATH."—DR. J. H. BENSON'S CASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your last number I see that Dr. Little objects to some of my remarks on a case of the so-called "black death" reported by me in your issue of the 24th April last.

One remark in particular he combats—viz., that "To the theory of those who are of opinion that this disease is connected with cerebro-spinal meningitis, this case at least lends no support."

Dr. Little has advanced the theory that "black death" is connected with cerebro-spinal meningitis, and many others have adopted it.

Without, for a moment, wishing to doubt that Dr. Little's theory may prove to be true, I am reluctant, I confess, to adopt

it until sufficient evidence of its truth be produced, and very unwilling to allow that *my* case "proves, in a remarkable degree," such a connection, as Dr. Little says it does.

The objection on the part of Dr. Little, to the remark referred to, probably arose from the fact that I neglected to describe, in my communication on the subject, the character of the congestion, which was marked in almost every organ of the body in a greater or less degree, and, among the number, on the brain and spinal chord. I am perfectly aware that the presence of the products of inflammation is not necessary to prove the existence of meningitis (though, as the patient was three days ill, there was time for such products to be formed), but the presence of, at least, capillary congestion is; and yet there was no such congestion whatever found on the most careful examination, during which it was looked for particularly. This I intimated when I said, "Neither on the upper or under surfaces of the brain, nor in its membranes, was there the least *sign* of recent inflammation to be found." And again, when speaking of the chord, "The substance of the same was of natural consistence, and not the least *trace* of inflammation was anywhere observable." The congestion was, to all appearances, passive, and only apparent in the larger veins, and in the sinuses.

The softening of the brain substance referred to was so very slight, that it was a matter of doubt among my colleagues, at first, whether it had any real existence; and certain it is that the softening was not inflammatory.

As to the fluid in the lateral ventricles, mere passive congestion would be quite sufficient to cause that without any inflammation. The same condition was found in the pericardium and in the areolar tissue about the kidney, without inflammation.

Dr. Little says that he remarked in his paper, to which he referred, that "implication of the cerebro-spinal and sympathetic systems formed a prominent and early feature in the disease;" but the case in question has given no evidence that that implication is meningitis, and certainly does not *prove* it.

With reference to the symptoms which Dr. Little quotes in support of his theory, I am quite sure he will not now feel himself justified in ascribing them to meningitis, since there was no post-mortem evidence whatever to bear out that view. We know that many, and the most important, of those symptoms appear in other diseases in which the implication of the nervous system is merely functional.

I may add that Dr. Belcher, in the remarks which that accurate observer makes upon the interesting case which he details in the last number of THE MEDICAL PRESS AND CIRCULAR, refers to the very case in question, and says, "It goes far to show that there is no necessary connection between the cutaneous discolouration and cerebro-spinal arachnitis."—I am, dear sir, yours, very truly,

JOHN HAWTREY BENSON, M.B., &c.

### PRELIMINARY PROFESSIONAL EDUCATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It must be admitted, by any unbiassed thinker, that Preliminary Professional Education is still in a very unsatisfactory condition. A young man who proposes to practise the most scientific profession in existence, is admitted within its ranks without having acquired any basis of general scientific education whereon to rear his special scientific knowledge, nay, even without having shown that he possesses any capacity whatever for scientific thought, or any acquaintance with scientific methods. We do not so rear our architectural structures, but lay a broad and deep base first, and then erect the column. The field which is to bear the humblest cross is cultivated, laboured, manured, and its capabilities ascertained, before precious seed is entrusted to its bosom; but we expect the richest crop the human mind can grow to flourish in an untilled soil, nay, where, for anything we know to the contrary, there may be absolutely no soil to till. We expect that a professional man will everywhere be recognised as a gentleman, but we neglect insisting on the first qualification for the character, the possession of a well-cultivated mind.

Let any unprejudiced person say whether being able to boggle through a dozen pages of Greek, and twenty of Latin, constitutes such education as a gentleman ought to possess, or affords any test whether a man can, with credit, practise such a profession as medicine or no. Let it be remembered that, in nine cases out of ten, the general education which a man has acquired before he enters on the study of medicine, is that which must serve him all his life, for the arduous labours on which he must engage, first in the study, and then in the practice of his profession, will leave him but little time or oppor-

tunity for continuing his general education subsequently. But, on the other hand, we do not expect that the ranks of medical students will be recruited by young men from the spade or the plough, but from those who shall have devoted their boyhood to preparing their minds for the professional task they have set themselves, and, therefore, it would not be unreasonable to ask from them much higher proofs of capacity and of diligence than are in general demanded at present.

Moreover, it is certainly but fair to the young men themselves, that those of them who have not capacity to pass their professional examinations, and to earn their livelihood decently in the profession should be weeded out by the preliminary examination. That a man should have passed the preliminary, and yet fail from want of capacity at the professional examination ought to be unheard of. Much better for them if, before they should have thrown away four or five of the best years of their life in studying for a profession which they can never practice with success, they should be candidly told, "You had better seek your bread otherwise, for you have not the qualifications of mind necessary for medicine." And, I conceive, that preliminary education might be so directed as to develop these qualifications, and preliminary examination so conducted as to test them.

Let us consider what these qualifications are, and how best they may be developed. We may enumerate the following:—

1. Habits of patient through investigation.
2. Minute accuracy of observation.
3. The power of reasoning correctly from effects to causes.

For the first of these there could be no better training than that involved in an extended course of classical education, and this quite apart from its well-known effect in refining the mind, and giving a tone of elegance and culture to it.

But such a course of classical education is hardly ever sought for at the preliminary examinations, notwithstanding that it might easily have been gone through during the years presumed to have been spent at school; for, of course, it is not the classical education of the scholar that ought to be asked for, but that of the gentleman. Since, however, the colleges cannot do what the universities do in order to ensure a sufficiently extensive course of reading—namely, prescribe series after series of authors to be studied, term after term, for years, what plan might the medical boards adopt as affording a sufficient test of classical knowledge at a single examination? One very simple, but, at the same time, perfectly satisfactory, method—namely, let the examination be not in a short prescribed passage, or, at least, not in that merely, but in the language in general; not *Livy*, but *Latin*; not one of the gospels, but *Greek*. I do not mean to say that a man should be handed *Cicero de Oratore*, or a chorus of *Sophocles*, but let some plain easy author, say *Cicero's Orations*, or *Cæsar* or *Livy*; or in *Greek*, *Herodotus* or *Xenophon*, be put into his hands, and try what he knows of the language, making every allowance for the fact that he is supposed never to have seen the passage before, and expecting from him, as I said above, not the knowledge of the scholar, but such an acquaintance with the language as a gentleman ought to possess, and a schoolboy of fair abilities may reasonably be supposed to have acquired at the age of 17 or 18. Does this seem too much to ask? Let us recollect that it is the class of badly educated men, and those who are of inferior capacity, that overstock the professional labour-market, and so deprive their brethren of the due recognition of their professional labours by the public.

2ndly. As regards minute accuracy of observation.

Three lines of study seem to me particularly suitable for training and testing this quality in the case of medical students. One of these, being a *sine quâ non* of even decent English education, is already adopted by, I think, all the colleges, but might, perhaps, be more emphatically insisted on—namely, English spelling—a deficiency in which seems to me to point out, at once, not neglect of study, for I doubt if a man could even become a correct speller by study, but some inherent mental defect which incapacitates a man from accuracy of observation. The second subject of study under this head is geography as per map, not as per book; and this, I think, peculiarly suitable for medical students, for surely the man who is unable to carry in his mind's eye the relations of countries, rivers, and seas on a map-sheet will hardly be competent to master the far more intricate and numerous relations of human anatomy.

3rdly. Of all means of training the mind to minute and accurate observation, perhaps the study of field botany is the most direct and powerful, and inasmuch as this is a subject in-

variably prescribed for medical study, it can make but little difference to the student if it should be made a part of the preliminary rather than of the professional examination. Indigenous orders only should be prescribed, and as a test of accuracy of observation, such a subject of study would be invaluable as an addition to the preliminary examination.

Now, as to the power of reasoning correctly from effects to causes; this is, perhaps, the most important of the faculties that the medical practitioner is called upon to exercise; given phenomena—*i. e.*, signs and symptoms, he has to trace the cause—*i. e.*, to diagnose the disease. It is needless to insist that such a faculty ought to be trained and developed from the earliest years of the youth who is to be a medical man, and its existence fully and even severely tested before he is admitted to the study of a profession in which, if deficient in this faculty, he can never be anything better than a blundering quack.

And what line of study will serve best to develop this most essential faculty? None certainly can be better than that of the various physical sciences, whose very object and aim it is to enquire into the causes of phenomena; let us enumerate astronomy, geology, physical geography, meteorology, and chemical physics, the last two being almost necessary subjects of a medical man's study; finally, let us add mechanics, or if we said generally mathematical physics, so as to include hydrostatics and optics, the latter peculiarly belonging to a medical man, so much the better; for how can a man understand the mechanics of the human body, the structure of bones, the action of muscles, &c., if he is ignorant of the general principles of which we have here, these special applications? It is almost unnecessary to add that geometry and algebra are necessary preliminaries to these studies. I have suggested a pretty extensive course, but let it be remembered that a man must generally depend for life on the science he studies before he enters on his special professional pursuits, and that six or seven years of careful teaching ought to qualify him in the above subjects, say from the age of twelve or thirteen on, while a year of special metropolitan teaching would be well spent in arranging and cementing together the materials he might previously have accumulated. I do not think there is a single subject in the above course of study that could *properly* be omitted from the preliminary test examination of a man who is to practice his profession with anything like safety to the public or credit to himself. In another letter I shall, with your permission, say a few words on the subject of the age for commencing medical studies.—I am, sir, your obedient servant,  
ISAAC ASHE, A.B., M.B., Eblan.

#### THE ADVANTAGES OF VEGETARIAN AND TEMPERANCE MEDICAL PRACTICE IN THE LONGFORD WORKHOUSE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—IN THE MEDICAL PRESS AND CIRCULAR of the 6th March, Mr. J. Haughton, reiterates his statement respecting the advantages of Dr. Nichols' vegetarian and temperance medical practice, in the Longford Workhouse; and, as economy is desirable, if it can be had without loss of life or of health, and particularly if proved to save either or both, I have lately examined a considerable mass of documents, to ascertain if there be real grounds for the statement that there has been a low mortality in the Longford Workhouse. The subject is one of much interest, as about 120,000 persons are annually treated for medical and surgical diseases in the Irish workhouses, in which the mortality is between 12,000 and 13,000 yearly.

The documents which I have examined are the Census Commissioners' Reports for 1851 and 1861, and the Poor-Law Commissioners' Reports from the commencement. These documents appear to supply ample materials, from which a fair comparison can be made between the results of Dr. Nichols' practice, spread over a long series of years, and the average of the practice of all the other Workhouse Medical Officers in the same years.

I shall first notice Dr. Nichols' Fever and Infirmary Report, which Mr. Haughton puts forward as proving a low mortality. It is—"Fever Hospital, remain, 0; interns, 10; externs, 41; total, 51; of whom 43 recovered, 6 died, and 2 remained." This was a mortality of 1 in 87 on the admissions, or 11.76 per cent., whilst the last published reports of the Cork-street and Hardwicke Fever Hospitals, and of the fever wards of the Meath, show a mortality of 1 in 14 $\frac{3}{4}$ , or 6.84 per cent., the admissions being 3439, of whom 235 died.

Dr. Nichols' Infirmary report is:—"Remain, 60; admitted

interns, 491; externs, 272; total, 823. Recovered, 737; died, 45; remain, 41." This was a mortality of 1 in 17, or of 5.75 per cent., whilst that in 5228 patients admitted in a year into Steevens', the Meath, and the Whitworth, and Richmond Hospitals, was only 191, which is 1 in 27, or 3.65 per cent. It may be said that the Longford returns should rather be compared with those from other workhouses, but the Poor-Law Commissioners' Reports do not contain the necessary data to distinguish the mortality of the fever class.

The following have been carefully, and, I think, correctly, compiled from the Census Commissioners' Reports of 1851 and of 1861, and from the Poor-law Commissioners' Reports down from 1841:—

"1. From 1842 to September, 1865, the Irish Workhouses admitted 7,768,022 persons, and 483,773 died in them. This was a mortality of 6.22 per cent., or in the proportion of one to every 16 admitted. During that period, the Longford Workhouse admitted 51,791 persons, of whom 4535 died, which was a mortality of 8.77 per cent., or one in 11-two-fifths of the admissions. It appears from these returns, 1298 more died in the Longford Workhouse during that period than would have died had the rate of mortality in it been the same as the average of all the other workhouses.

"2. During the twenty years ended 1861, 48,325 persons died of fever in all the workhouses, which was one in 136 of the paupers that were admitted, or 0.73 per cent.; and 1080 died of fever in the Longford Workhouse, which was one in 48 of the number admitted, or 2.43 per cent.

"3. 174,257 persons died of zymotic diseases during these twenty years in all the workhouses, which was a mortality of one in 38-one-fourth on the number admitted, or 2.60 per cent., and concurrently 2256 died of zymotic diseases in the Longford Workhouse, which was a mortality of one in 18 $\frac{1}{4}$  or 5.44 per cent. These returns show that 775 more died of fever, and 1065 of all zymotic diseases in the Longford Workhouse, during these twenty years, than would have died had the mortality been only equal to the average in all the workhouses.

"4. Diarrhoea is a disease that often depends on insufficient diet, or on that which is not at the time suited to the patient. During these twenty years, one in 52 of all the admissions into the Longford Workhouse died of that disease, whilst only one in 233 died of it as the average in all the workhouses. How many that sunk under it in the Longford Workhouse would have survived under a generous meat and soup diet, it is now useless to inquire, but that for persons in diarrhoea such diet is scarcely ever omitted in public institutions or in private families is certain, and that it assists in saving life, and in the alleviation of suffering, is well-known."

These official returns show that in place of being low, as Dr. Nichols and Mr. Haughton represents, and, perhaps believes, the mortality has been much higher in the Longford Workhouse than the average of the other houses. It is true that, latterly, the mortality in that workhouse is comparatively less; but, at the same time, there are circumstances to make one apprehend that the fever cases in that union are not nearly as much benefited by its fever hospital as those in other Unions are, or rather that they do not so much avail themselves of it as the fever class in most unions do. This, if it be the case, in those, in this, or in any other union, is a subject of much importance, and I will endeavour to explain the grounds on which I found my belief that it is so.

1. For twenty years the annual admissions into all the workhouses averaged about one in 20 of the whole population, and those into the Longford Workhouse was an average of one in 16 of the population of that union, showing one-fifth more pauperism in the latter. Again, the annual number of fever cases admitted into all the workhouses during that period (assuming that about one in ten of that class died) was one in 237 of the population, whilst that annually admitted into the Longford Workhouse was one in 61 of the union population. And, again, zymotic diseases were annually admitted into, in the proportion of one to about 666 of the whole population, and into the Longford Workhouse as one in 282. These returns not only mark a high comparative degree of pauperism in the Longford Union, but also a high comparative mortality extending over a long period.

2. For several years one in 12 $\frac{1}{4}$  of the population of the Longford Union has been received into the workhouses, whilst only one in 18 of the population of all the Leinster Unions has been admitted. This shows the pauperism of the Longford Union to be one-third higher than that of Leinster yet.

3. In the ten years ended 1865, though 35,384 fever cases, or one in 42-one-fifth, of the Leinster population were

received into the workhouses, only 306, or one in 107 of the population of the Longford Union, were admitted. Now, as the pauperism of that union was much higher than the average of that of the Leinster unions, it is reasonable and logical to assume that fever prevailed there at least in the same ratio as in them, and, assuming that to have been the case, there would have been 846 fever cases to be admitted. From this, it would seem that 540, such as would have availed themselves of the advantages of the fever hospitals of the Leinster workhouses, did not seek that of the Longford Fever Hospital. (And let me observe, that if these 540 were admitted, the mortality would be much higher.)

If that be the case, there must be some cause or causes for it. The class that supplies paupers to workhouses, and patients to fever hospitals, know as well as the wealthy that, in the progress of fevers, some spirituous stimulant, as well as some light soup, is much used, and much relied on, and they also know that a light meat diet considerably helps convalescence.

But, as they know that neither is to be had in the Longford Workhouse, is it not likely that many fever cases refuse to go there, or are prevented by their friends from going, as those (supposed) advantages are not to be had in it?

If, as these data appear to show, there has been higher mortality in the Longford than in the other workhouses, and if any considerable number of the fit objects for hospital relief be unwilling to go into the hospital there, no saving as to the quantity of the articles of meat and fermented liquors that would be really required can compensate for the injury that must arise. The cost for spirituous stimuli in the Dublin fever hospitals does not exceed an average of about 18d. per patient; it is often less; to dispense with it, or with some animal food in hospitals appears to be an experiment that should only be permitted on better proof than Dr. Nichols and Mr. Haughton have offered. If the medical attendants of Fever Hospitals in Dublin and elsewhere, find it necessary to watch anxiously the effect of spirituous stimulants on these fever patients, and that they have grown grey in that practice, it is not to be supposed that they adhere to it without the assurance that they are doing right. A member of the profession who entirely discards these particular means of curing the sick, undertakes serious responsibility; the colleges have objected to homœopathic practitioners, and public departments have done the same. In my mind, Dr. Nichols' system is, at least, as objectionable and far more likely to be injurious.

Should these data and observations have any effect in preventing the Longford practice from being followed elsewhere by Boards of Guardians, the labour I have had in collecting the materials, and it was not small, will be recompensed.—I am, yours, &c.,

DENIS PHELAN.

P.S.—“The average cost per head for all that were relieved in all the workhouses up to 1850, was 40s. 9d.—in Longford it was 36s. 8d.; from thence to 1865, included, the average in all the workhouses was 34s. 8d.—in Longford 39s. This shows that since Dr. Nichols got rid of meat and fermented liquors, the cost per head for each person that got relief in the Longford workhouse was 4s. 4d. more than in the others. In this calculation, every four cases on out-door relief, are considered as one on in-door. I give this calculation to show that Dr. Nichols' treatment does not make the cost less than the general averages, but that it rather increases it.”—D. P.

#### LODGMET OF A COIN IN THE ŒSOPHAGUS. DISLODGED BY MANIPULATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR—J. C., ret. 32 years, came to me on the 23rd inst., in a state of great alarm and excitement, and informed me that while amusing some of his children, by pretending to swallow a halfpenny, it had “accidentally gone down his throat.” He complained of a sense of uneasiness at the upper part of the sternum, and a slight feeling of suffocation. I examined the pharynx without being able to discover any foreign substance, but on examining the neck externally, I detected a projection in the œsophagus, about two and a-half inches from the termination of the pharynx. The projection had a smooth, round feeling to the touch, and was evidently the edge of the coin as it lay in an oblique direction across the œsophagus; on pressing this projection pain was complained of.

I gave the patient a mouthful of soft bread, which, however, had not the effect of dislodging the coin, as the projection still remained, and the patient expressed a feeling as if the bread had stuck in the œsophagus, and had not passed down into

the stomach. Before resorting to the use of the probang, I thought I would try the effect of manipulation, with a view of dislodging the coin from its position, and so give it the chance of passing down into the stomach. I accordingly endeavoured, by gentle manipulations, to push the edge of the coin upwards, and thus remove it from lying flat, or partially so, across the gullet, and after about five minutes exertion the projection suddenly disappeared, and the patient expressed himself considerably relieved. I now gave him a mouthful of water which he swallowed, and immediately afterwards a mouthful of soft bread, which he likewise swallowed, though with some pain. Considering from the above circumstances that the coin had passed down into the stomach, I directed the patient to take a purgative at bed-time, and to carefully examine the fæces in the morning. My directions were attended to, and the patient discovered, in the fæces, the coin which had been the cause of all his alarm.

JOHN GEO. THORNLEY, M.D.

#### DOMICILIARY SANITARY INSPECTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Observing the paragraph on the above subject in your last number, I shall be obliged if you will allow me to make one or two observations, by way of explanation. The idea that I had in view, was for private householders to make their own selection in the appointment of a Sanitary Inspector, and I therefore referred to the plan as “voluntary.” Under such an arrangement no general fund would be necessary for the purpose, as each inspector would be engaged, and paid by the family making the appointment; a very economical arrangement it would undoubtedly prove, in the prevention of individual sickness, and consequently the preservation of Public Health. This last consideration ought to weigh with the authorities, and I believe it would be a most important step in the interests of the public, if the General Board of Health would make it compulsory upon local boards to appoint female sanitary inspectors, at a fixed salary, whose duty it would be to make a house to house visitation at stated periods, the expenses to be defrayed out of the general purpose rate. In order to meet the objections of individuals to such official inspection of their premises, notice might be given of the plan, and exemption could be made in cases where such objection might exist. I think the difficulties which are likely to be raised in the matter may be disposed of in the way proposed. I need only say, in reply to another observation which you make in the paragraph alluded to, that a lady, whether trained or untrained in sanitary matters, is to a great extent excluded from some corner of her own establishment, and those perhaps the most needing sanitary inspection and rectification.—I am, sir, yours, &c.

M. A. B.

#### OPERATION FOR STRANGULATED DIRECT INGUINAL HERNIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was called on the 22nd March to see Mrs. M., aged 60, suffering from strangulated direct inguinal hernia. Dr. Fleming of this town had been in attendance; he tried to reduce it, but owing to the length of time it had been down—one year, without ever being returned, and adhesions formed—as a matter of course he could not reduce it. The hernia was the size of a hen egg. I performed the operation, assisted by Dr. Fleming, and my son, Dr. Albert Lane, kept her under the influence of chloroform. I had some little difficulty, on account of the adhesions, but otherwise none. The patient did not lose half an ounce of blood during the operation. On the fourth day she had an attack of diarrhœa, a little chalk mixture soon set it to rights. On the fifth day she was up and as busy as a bee, and had not a minutes pain or ill health since.—I am, sir, yours, &c.

WILLIAM LANE, M.D.

Newtownlimavady, May 2nd, 1867.

#### ON THE PURIFICATION OF WATER: A NEW METHOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to the article in your paper of 1st inst., “On the Purification of Water, a New Method,” I regret you have been misinformed as to the Proprietorship of the Invention therein alluded to, the same being solely vested in the London and General Water Purifying Company Limited, and the testimonial therein referred to from Dr. Letheby was given

by that gentleman to this Company, and to no one else, as you will observe by enclosed copy of same.

The apparatus is on view at our Patent Cistern Filter Depot, and I may further mention that the Filtering Apparatus was the sole invention of a Mr. F. H. Danchell, and not of Mr. T. W. Tobin.—I remain, dear sir, your obedient servant,  
R. RUDING.

## Medical News.

**UNIVERSITY OF CAMBRIDGE, MAY 1ST—PROFESSORIAL CERTIFICATE EXAMINATION, APRIL, 1867.**—Regius Professor of Laws.—H. Rowan, Trinity College. J. T. Abdy and T. Waraker, Examiners. Anatomy—W. Roper, St. John's College. G. M. Humphry and Charles Lestourgeon, Examiners. The examinations for Medical and Surgical Degrees in the present term will commence on Monday, the 3rd of June, at nine A.M., in the Anatomical Schools. Candidates intending to offer themselves for examination are required to signify the same to the Regius Professor of Physic on or before the 20th of May, and to send at the same time their certificates. A fee of three guineas is paid to the Professor by each candidate when his name is sent in for his first examination for the M.B. degree. The final examination for the degree of M.B. under the old regulations will begin on the 3rd of June, as well as the first examination for the degree of M.B. under the new regulations, and the examination for the degree of Master in Surgery. The second examination for the M.B. degree under the new regulations will begin on Monday, the 10th of June, at nine A.M.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Court of Examiners on the 30th ult., and when eligible will be admitted to the pass examination:—

J. Ryall Rouch, W. Day Lovell, Robert Alcock, W. Howell Lloyd, H. Mason Jay, R. Garton Coombe, L. Fyson Cogan, Herbert Boyd, C. D. H. Drury, E. H. Downing, James Bilham, William Claridge, Bernard Duke, C. Hinds Lawrence, John T. Darby, A. E. B. Love, Charles Wood, J. Spottiswoode Cameron, W. R. Cheyne, J. E. Ward, Reginald Taylor, John Stride, E. Roger Rowland, T. Llewellyn Browne, Charles J. Oldham, E. Josephus Green, William Milligan, Owen Roberts, A. Shuter Duncan, John H. Morton, T. Lambert Lack, and H. Ensworth Jackson.

The following were examined on the 1st inst.:—

Messrs. Robert E. Grigson, J. Ashburton Thomson, John Hasard, Frederick Wicks, Edward Greaves, S. Stainton Brown, and E. Lorton Collins, students of Guy's Hospital; B. C. A. Esnouf, Edwin Rickards, and William Hardman, of University College; David W. Morris, John Adams, and Armand Leslie of the Middlesex Hospital; George Birt and W. Blakley Cochrane, of the Birmingham School; H. Schofield Baldwin and W. Bowen Davies, of St. Bartholomew's Hospital; Owen Williams and J. Gerson da Cunha, of St. Mary's Hospital; Charles J. Rix and T. Carleton Ralton, of Manchester; W. Augustus Hewett, of King's College; Charles H. Wainwright, of Leeds; J. Waters Harrison, of Sheffield; and William A. P. Anson, of Newcastle.

The following passed the same examinations on the 2nd inst.:—

Messrs. C. Wait Smith, Ernest G. Archer, Albert F. Field, and Barnfield Dayman, students of St. Bartholomew's Hospital; W. Horne Bailes, Adam J. Whitefoorde, J. Lawrence Bullock, and L. Victor Dubois, of University College; A. Milwood Sculthorpe, J. Lloyd Roberts, Thomas Standish, and William Morris, of the Birmingham School; James Dunne and H. Widenham Maunsel, of Dublin; R. Hodgins Lloyd and Frederick Morgan, of the Westminster Hospital; John Porter and Samuel Buckley, of the Manchester School; W. L'Heureux Blenkarne and J. Dungey Roberts, of Guy's Hospital; William Hughes and Robert Griffiths, of Glasgow; J. Herbert Wade, of St. George's Hospital; Alfred Kelly, of King's College; W. Derrickson Beard, of St. Mary's Hospital; W. J. C. Ward, of Edinburgh; W. T. G. Leapinwell, of the London Hospital; and W. Poulton Lee, of the Middlesex Hospital. It is stated that 23 candidates out of the 108 who offered themselves for this primary examination failed to acquit themselves to the satisfaction of the Court, and were consequently referred to their anatomical studies for a period of three months.

**APOTHECARIES' HALL OF LONDON.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practice, on the 25th ult.:—

Daniel King, Stratton, Cornwall; Henry Child Buckley, Llanelly, Carmarthen; Arthur Eisdell Fluder, Lyminster, Hants; Robert King, Alfred-place, Bedford-square; Hugh James Lloyd, Dolgelly, North Wales; William Joseph Marsh, Nottingham; William James Todd, King's College Hospital.

The following gentleman also on the same day passed his first examination:—

William Croudson Barnish, Manchester Hospital.

At the preliminary examination in Arts held at the Hall on the 26th and 27th ult., 69 candidates presented themselves, of whom 22 were rejected, and the following 47 passed, and received certificates of proficiency in General Education:—

C. E. Adams, E. L. Archer, E. O. Bark, W. T. Benham, R. Bower, J. P. Cartwright, G. C. Cheyne, J. Coudrey, Cecil Drake, R. W. Edgington, E. W. Freeman, M. C. Hallows, W. Hanson, P. T. G. Head, W. C. Head, A. M. Hynes, C. G. Jones, Alfred Kay, J. N. Kiddell, J. C. Kirby, W. T. Law, J. A. T. Lang, G. T. Langridge, H. A. Lawton, John Litt, W. L. Mayer, C. J. C. Mitchell, E. W. Moore, P. W. G. Nunn, J. H. Osborne, E. J. Parrott, G. R. Priddle, A. C. Raine, O. R. Richmond, P. J. Robey, Walter Shaw, John Spear, F. Stedman, E. F. Thomas, W. Tomlinson, E. B. Trotter, J. S. Trousdale, H. Waldo, A. J. M. Walker (certificate of special proficiency), W. J. Walsham, J. F. Weatherhead, and Richard Williams.

**UNIVERSITY OF ST. ANDREW'S.—Pass List.—The**

DEGREE OF M.D.

Thomas J. Blake, L.S.A.Lond., L.R.C.P.Edin.; William H. Brace, M.R.C.P.Edin., F.R.C.S.Edin.; William Elliott, L.F.P. and S.Glasg., L.S.A.Lond.; John R. Pothergill, L.R.C.S.Edin.; George Aug. Jeffery, M.R.C.S.Eng, L.S.A.Lond.; Alexander Johnston, M.R.C.S.Eng., L.S.A.Lond.; James Liburne, L. and F.R.C.S.E., Surg. R.N.; Thomas Lloyd, F.R.C.S.E., L.S.A.Lond.; John Denis Macdonald, M.R.C.S.Eng., Staff-Surg. R.N.; Edward Richardson, M.R.C.S.Eng., L.S.A.Lond.

**UNIVERSITY OF ABERDEEN.—Pass List.—The**

DEGREE OF M.D.

Edwin Burrell, London; James D. Mackay, Coghill, Edinburgh; Peter Cullen, Bengal; Henry Eales, London; Henry Wm. Williams, Northampton.

PROMOTED TO THE DEGREE OF M.D.

George Henry Anderson, Middlesborough, York; Stewartson Clark, Banff; Alfred Swaine Lethbridge, Axminster, Devon; George Mackie, Insh; George Mair, Turrif; Douglas Moir, Manchester; John Murray, Aberdeen; George Frederick Wales, Belfast; Charles James Wills, Brighton, James Yates, Oldham.

THE DEGREE OF M.B.

Alfred Henry Anthonisz; Henry Child Buckley, Llanelly, Carmarthen-shire; James Cameron, Laurencekirk; James Charles Gordon Carmichael, Maryculter; James Allan Coutts, Kincardine O'Neil; John Craigie, Doddington, Kent; George Henry Roque Dabbs, Newport, Isle of Wight; Alexander George Duncan, New Pitsligo, Aberdeenshire; James Farquhar, Buckie, Banffshire; Robert Grant, Tomintoul, Banffshire; John Thomas Hughes, London; Frederick William Jackson, Broadstairs; Sydney Johnson, Laxton, Nottinghamshire; Hugh Johnstone, Savoch, Aberdeenshire; Timothy Lewis, Narberth, South Wales; Charles Maclean, Kiltarn, Ross-shire; Alexander Hunter Mair, Savoch, of Deer; John Sturrock Mitchell, Letham, Forfar; Alexander Reid, Gartly; Alexander Le Rossignol, Jersey; Arthur Stephen, St. Cyrus, Kincardineshire; Henry Shinglewood Taylor, Alton, Hants; Wentworth Rayner Tindale, Peckham Rye.

THE DEGREE OF C.M.

Alfred Henry Anthonisz, Henry Child Buckley, Edwin Burrell, James Cameron, James Charles G. Carmichael, James D. Mackay Coghill, James Allan Coutts, John Craigie, Peter Cullen, George Henry R. Dabbs, Alexander G. Duncan, Henry Eales, James Farquhar, Robert Grant, Sydney Johnson, Hugh Johnstone, Timothy Lewis, Charles Maclean, Alexander Hunter Mair, John S. Mitchell, Alexander Reid, Augustin Le Rossignol, Arthur Stephen, Henry S. Taylor, Wentworth R. Tindale, Henry W. Williams.

Of the above-mentioned, the following passed with Highest Academic Honours:—

James Cameron, James Allan Coutts, Hugh Johnstone, Arthur Stephen.

And the following with Academic Honours:—

James Charles G. Carmichael, Timothy Lewis.

The following were declared to have passed part of their examinations:—

Charles Adam, George Ed. D'Arcy, Adams, Robert Reid Alexander, John Batten, James T. Crowden, Ed. L. Crowther, Frederick A. Davson, Thos. Birch Dyer, Alexander Forbes, Henry Grant, John S. Gunn, George W. Hutchison, James Ironside, Henry Kirwan King, Alexander Laurence, Alexander M'Arthur, Robert Macpherson, George William Mousley, Patrick Nicol, James Allan Philip, Ed. Payne Philpots, Richard James Quinell, John Robb, John Roberts, David Shirres, John Shives, George Alexander Simpson, David Sinclair, Joseph H. Smith, Francis W. Smith, Patrick B. Smith, Alfred C. Taylor, John L. Thomas, Hercules S. Traill, David Tulloch, Albert Williams, Richmond C. Willock, Alexander G. Wood, and Ed. R. Woodford.

**LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL, (IRELAND).**

FOR THE MONTH OF APRIL, 1867.

Hurley, John James, Tralee, County Kerry, L.R.C.S.I. 1866; L.M.K.Q.C.P.I. 1866.  
Sloes, Joseph, Surg. R.N., Portadown, County Armagh, M.D.Univ. Glas. 1846; L.R.C.S.Edin. 1847.  
Adrien, Edward William, Oldtown, County Dublin, M.R.C.S.Eng. 1865; L.K.Q.C.P.I. 1866.  
Stephens, William, Ballyshannon, County Donegal, M.D.Q.U.I. 1866; L.R.C.S.I. 1865.  
Thornton, Daniel, Hardwicke-street, L.R.C.S.I. 1865.

**SIR GEORGE DUNCAN GIBB, BART.**—Under the heading "A New Medical Baronet," the British Medical Journal announces that Dr. G. Duncan Gibb has succeeded to the Baronetcy of Gibb of Falkland, Fife. This instance cannot be properly held to be one of a Medical Baronetcy, inasmuch as it is an honour simply acquired by inheritance. The Baronet in the present case is the well-known author of the work on Diseases of the Throat and Wind-pipe, as seen with the Laryngoscope; and he is one of the Assistant Physicians of the Westminster Hospital.

**THE BRITISH PHARMACOPŒIA.**—We have to announce the appearance of the revised edition of the British Pharmacopœia. It has been prepared by Professor Redwood of the Pharmaceutical Society, and Mr. Warrington of the Apothecaries' Hall, London, under the direction of a Committee of the Council, consisting of the following members:—Dr. Burrows, Dr. Apjohn, Dr. Cristison, Dr. Sharpey, and the Honorary Secretary, Dr. Quain. It is a volume of very convenient size, post 8vo, is printed on excellent paper, in very good type, and in respect of size is a decided improvement on the edition of 1864, which was published in 8vo, and 32mo. We are obliged to defer, till next week, any commentary on the additions, alterations, or omissions in the present edition, merely premising that the high character of those concerned in its production, demands that whatever criticism we may feel bound to offer, should be strictly impartial, and should not degenerate into a mere lavish of praise, as is often the case in reviews of works on Medicine.

#### NOTICES TO CORRESPONDENTS.

##### "SEMI-EDITORIAL NEWSPAPER PUFFERY."

We publish the following note as a corollary to our observations on the puffing of Professors Tanner and Corbett, of Cork:—

"TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

"SIR—I request that you will remove my name from the List of Subscribers to THE MEDICAL PRESS AND CIRCULAR.—I remain, yours,  
"W. T. TANNER."

A correspondent calls our attention to the very gross insolence of the porter at the Army Medical Office in Whitehall. It appears from the statement of our correspondent, who is quite incapable of a misrepresentation, that the insulting rudeness of this person has been repeated more than once. The simple course to be taken to prevent insolence from such understrappers is to lay their conduct before their superiors, who would, we are certain, visit it with condign punishment.

*Mr. Henry Smith, 33, Norfolk-street, Strand,* has drawn our attention to the article on "The Purification of Water," which appeared in our columns last week. Mr. Smith states that the apparatus therein mentioned is the property of his clients, the Directors of the London General Water Purifying Company, as transferees of the patent of Mr. Danchell, and that it can be seen in operation daily at the premises of the Company, 157, Strand.

*Mr. Parker, Bath.*—Mr. Faget having promised to consider the merits of your splints, we think it courteous to so eminent an authority to postpone any discussion.

*Dr. Craft, St. John's Wood.*—The law of libel is so framed, that even the publication of facts, where any individual is personally concerned, can be made actionable. There are, as you observe, many "official puppies" in existence, to whom the administration of leather would probably not be a new operation. The publication of their names, however, might have a very different effect, and lead to expensive litigation. We should, in the present case, advise you to lay your complaint before the chief of the department.

*Inquirer.*—The statutory lectures recently delivered at the Royal College of Physicians, and of which we gave an abstract under the titles of the Croonian, the Gulstonian, and the Lumleian, derive their names from the founders Drs. Croone, Gulston, and Lumley. They are delivered annually with certain restrictions.

#### ERRATUM.

In Dr. Little's letter on Dr. Benson's case, read "presence" instead of "absence" of meningeal adhesions, &c.

#### MEDICAL APPOINTMENTS.

**ALLEN, J.**, M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Ripley District of the Belper Union, Derbyshire, vice W. H. Fletcher, L.S.A.L., deceased.

**BATT, C. D.**, M.R.C.S.E., has been appointed Assistant House-Surgeon to the Sheffield General Infirmary, vice A. C. Turner, L.R.C.P., resigned.

**BRIDGMAN, I. T.**, M.R.C.S.E., has been appointed Medical Officer for the Berkeley District of the Thornbury Union, Gloucestershire.

**CHAMBERS, DR.**, has been appointed Medical Officer to the Workhouse of the Bailleborough Union, Co. Cavan, vice J. Levey, M.D., deceased.

**CLARKE, T.**, M.R.C.S.E., has been appointed Medical Officer for the Poulton District of the Fylde Union, Lancashire, vice R. H. Bowness, M.D., resigned.

**CRANKE, R.**, L.R.C.P.Ed., has been appointed Medical Officer for the Ulverstone District and Workhouse of the Ulverstone Union, Lancashire, vice H. Seatie, M.R.C.S.E., deceased.

**ELLIOTT, J. R.**, L.K.Q.C.P.I., has been appointed Medical Officer for the 11th District of the Barnstaple Union, Devon, vice J. Clarke, M.R.C.S.E., resigned.

**LEAF, W.**, M.R.C.S.E., has been appointed one of the Surgeons to the St. Marylebone General Dispensary, vice J. Brighthouse, M.R.C.S.E., resigned.

**LEVICK, G.**, M.R.C.S.E., has been appointed Hon. Surgeon to the 5th Essex Rifle Volunteer Corps. Mr. Levick has also been appointed Divisional Surgeon to the Plaistow Station of the K Police, vice E. J. Morris, L.R.C.S.I., deceased.

**MEGGETT, A.**, M.R.C.S.E., has been appointed Medical Officer to the Scarborough Union District, vice W. H. S. Wilson, deceased.

**MONKS, E. H.**, M.R.C.S.E., has been appointed Medical Officer for the Ince District of the Wigan Union, Lancashire.

**NEWMAN, A.**, M.B., has been appointed Medical Officer for the Town-stal District of the Totnes Union.

**RABLAH, J. J.**, L.F.P. & S. Glas., M.R.C.S.E., has been appointed Medical Officer to the Scarborough Workhouse, vice W. H. S. Wilson, L.S.A., deceased.

**SIMMONS, B.**, M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Charfield and Totworth Districts of the Thornbury Union, Gloucestershire, vice Hicks, resigned.

**STEVENSON, T. M.D.**, M.R.C.P., has been appointed an Examiner in Forensic Medicine in the University of London.

**WALLER, J.**, M.R.C.S.E., has been appointed Resident Medical Officer to the Western General Dispensary, Marylebone-road, vice Richard L. Shone, M.R.C.S.E., appointed Resident Medical Officer to the Kensington Dispensary.

**WELCH, T. D.**, M.A., M.D., has been appointed Physician to the Kent and Canterbury Hospital.

**WRIGHT, R. T.**, M.D., has been appointed Resident Physician to the Queen's Hospital, Birmingham, vice T. A. Wood, M.D., resigned.

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

#### BIRTHS.

**JERRARD.**—On the 4th ult., at Honiton, Devon, the wife of Dr. Jerrard, of a son.

**WALKER.**—On the 10th ult., at Wooler, Northumberland, the wife of R. Walker, M.D., of a son prematurely.

**HISLOP.**—On the 16th ult., at St. George's-road, Glasgow, the wife of J. Hislop, M.D., of a son.

**PRINGLE.**—On the 17th ult., at Rutland-square, Edinburgh, the wife of Dr. Pringle, late of the Madras Service, of a daughter.

**CULLEN.**—On the 19th ult., at Rowanlea, Alexandria, Dumbartonshire, the wife of J. F. Cullen, M.D., of a daughter.

**BUCHANAN.**—On the 21st ult., the wife of George Buchanan, M.D., of Harley-street, of a daughter.

**LLOYD.**—On the 29th ult., at Grange-road, Bermondsey, the wife of Albert Lloyd, M.R.C.S., L.S.A., of a daughter.

**DAY.**—On the 29th ult., at Manchester-square, the wife of W. H. Day, M.D., of a son, who survived his birth a few hours.

#### MARRIAGES.

**LEWIS, PRICE.**—On the 24th ult., at St. Woolas Church, Newport, David Lewis, Surgeon, youngest son of David Lewis, Esq., R.N., of Newcastle-in-Erlyn, to Susan, eldest daughter of Capt. James Price, R.N.R., of Newport, Monmouthshire.

**WADD, BURDON.**—On the 30th ult., at the Church of St. Mary-the-Virgin, Kilburn, Frederick John Wadd, Surgeon, of Beaconsfield, Bucks, to Maria Louisa, daughter of Thomas Burdon, Esq., of Kilburn.

**HUNTER, COOPER.**—On the 30th ult., at the Church of St. Thomas, Portman-square, Wm. Frith Hunter, Esq., youngest son of the late George Yeates Hunter, M.D., J.P., of Margate, to Jane, eldest daughter of H. Cooper, Esq.—No Cards.

**COCKS, JONES.**—On the 30th ult., at Goodrich, Herefordshire, Cary Cocks, M.D., of Ross, son of the late W. Cocks, Esq., and grandson of the late Rev. Thomas Underwood, Rector of Ross, and Canon of Hereford Cathedral, to Mary Jane, second daughter of the late Walter Jones, Esq., of Sugwas Court, in the same County.—No Cards.

#### DEATHS.

**GATEHOUSE.**—On the 27th ult., at Bowlish Cottage, Shepton Mallet, Charles Gatehouse, M.R.C.S., L.S.A., aged 72.

**SKEVINGTON.**—On the 26th ult., John Skevington, F.R.C.S.E., of Ashbourne, Derbyshire, aged 60.

**WILSON.**—On the 8th ult., W. H. S. Wilson, L.S.A., of Scarborough.

## Original Communications.

## ON DREAMING, CONSIDERED ESPECIALLY IN RELATION TO INSANITY.

By THOMAS MORE MADDEN, M.R.I.A.,

LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND, MEMBER OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, AUTHOR OF AN ESSAY "ON INSANITY AND THE CRIMINAL RESPONSIBILITY OF THE INSANE," "ON CHANGE OF CLIMATE, A GUIDE FOR TRAVELLERS IN PURSUIT OF HEALTH," "THE SPAS OF GERMANY, FRANCE, AND ITALY," &c., &c., &c.

(Continued from page 438.)

## XI. THE PATHOLOGICAL INDICATIONS FURNISHED BY DREAMS (continued).

SEVERE fevers are also very frequently preceded for days by "Paroniria," or morbid dreaming, which is probably produced by the direct action of the fever-poison on the highly sentient brain-structure before it occasions its constitutional symptoms. The exanthemata are very commonly presaged by fearful dreams. Rhazes, the Arabian physician of the ninth century, notes, among the signs of approaching small-pox, "terrors in sleep." He regarded this prognostic as of considerable importance, and says, "When, therefore, you see these symptoms, or some of the worst of them (such as the pain of the back, and the *terrors in sleep*, with the continued fever), then you may be assured that the eruption of one or other of these diseases is nigh at hand."<sup>(1)</sup> Intermittent fever is often announced several days before any of the recognised symptoms set in, by persistent dreams of terrifying character. I have experienced this in my own person, and heard it confirmed by other sufferers on the African coast. The following case of morbid dreaming, ushering in yellow fever, I subjoin in the words of the gentleman to whom it occurred, himself a medical man, holding a high official position on the Gold Coast when it occurred:—

"In the early part of 1840, I was an inmate of Cape Coast Castle, and as some repairs were then being made in the Castle, the room assigned to me was that in which the ill-fated L. E. L. (Mrs. Maclean), the wife of the Governor of Cape Coast had been found dead, poisoned by prussic acid, not very long previously. I had known her in London, and had been intimately acquainted with her history, and much interested in it. Her body had been found on the floor, near the door, and in front of a window. After a fatiguing excursion to some of the adjoining British settlements on the coast, having retired to rest, I awoke disturbed by a dream of a very vivid character, in which I imagined that I saw the dead body of the lady who had died in that chamber lying on the floor before me. On awaking, the image of the corpse kept possession of my imagination. The moon was shining brightly into the part of the room where the body had been found, and there it seemed to me, on awaking, it lay pale and lifeless as it appeared to me in my dream.

"After some minutes, I started up, determined to approach the spot where the body seemed to be. I did so, not without terror, and walking over the very spot on which the moon was shining, the fact all at once became evident and obvious that no body was there—that I must have been dreaming of one. I returned to bed, and had not long fallen asleep, when the same vivid dream recurred—the same waking disturbance occurring while awake. As long as I lay gazing on the floor I could not dispossess my mind of that appalling vision, but when I started up and stood erect, it vanished at the first glance.

"Again I returned to bed, dozed, dreamt again of poor L. E.'s lamentable end, and of her remains on the same spot; again awaked, and arose with the same strange results.

"There was no more disturbance that night of which, at least, I was conscious, but, when morning came, fever was on me in unmistakeable force, in its worst form, and par-

tial delirium set in the same night. I was reduced to the last extremity about the third or fourth night of my illness, when a conviction seized on my mind that it was absolutely essential to my life that I should not pass another night in Cape Coast Castle. I caused the negro servant I had fortunately brought out with me from England, to have a litter prepared for me at dawn, and, stretched on this litter, hardly able to lift hand or foot, I was carried out of my bed by four native soldiers, and was conveyed to the house of a merchant and countryman of mine, to whose care and kindness I owe my life. So much for a visionary precursor of fever on the West Coast of Africa."

In neuralgia, disturbed dreaming is occasionally a prominent symptom. In one obscure case I was led to make what I believe to be a true diagnosis from the indications furnished by the patient's dreams. The individual in question is a man aged about 45, of an anæmic habit, confined by a sedentary occupation, who, for many years, had suffered from hemicrania, which latterly has become more intense and the intervals shorter. A couple of days before the attack, his sleep becomes broken by unpleasant dreams, and when the paroxysm has attained its height, he invariably dreams that he is the helpless victim of a persecutor, who finishes a series of torments by driving a stake through his skull, after which he becomes insensible. During his recovery from each attack, he states that his dreams are of a most agreeable character, though so vague that he cannot give any account of them. The frequent repetition of this dream leads me to conclude that there is some osseous growth within the cranium, and that the vascular distention accompanying the neuralgic attack, occasions pressure upon this, giving rise to the sensation I have referred to, while the subsequent feeling of comfort results from that pressure being removed.

Cardiac disease and hydro-thorax, which occasionally interferes with the functions of the circulatory apparatus, are often attended with disturbed dreaming. "Persons," says Dr. Copeland, "labouring under disease of the substance or valves of the heart, are subject not only to imperfect or disturbed sleep, but also to fearful dreams; and if they fall asleep in an uneasy position, or on the left side, in some cases they generally waken up soon from a fearful dream, as falling down from a precipice, drowning, &c.; their dreams being more pleasant when the position is more comfortable."<sup>(1)</sup> "Paroniria" is also very frequently occasioned by disease or irritation of some remote part or organ of the body; and, in many instances, morbid dreaming may be directly traced to the influence of some article of diet. Thus, for example, I am acquainted with a lady who, if she takes tea in the evening, is not kept awake by it as some persons are, but when she falls asleep, is thrown by it into a state of horrible dreaming, from which she always awakes up suddenly, under the illusion that a number of shadowy figures are sitting crouched up on every chair in her room. She is quite sensible at the time of its being an hallucination, but still cannot banish this idea from her mind. I need not make any remarks on the analogy which this kind of dreaming presents to the symptoms of incipient insanity, although, in reality, very different from that state, as I already have spoken on this point in my comments on another case of this kind which I described.

## XII. THE TREATMENT OF "PARONIRIA," OR MORBID DREAMING.

Cases occasionally occur in medical practice in which the patient complains of nothing whatever but morbid dreaming, and its effects, and in which this one complaint, trivial as it might at first appear, is sufficient to destroy either his mental or bodily health, or both.

Some years ago, I had a patient under my care, whose principle complaint was "paroniria," as morbid dreaming has been termed by some writers, and a most formidable disease it was. This individual, who was a person of a highly nervous temperament, had been suffering for some

(1) Rhazes "On the Small-pox and Measles." Translated from the Arabian by Dr. Greenhill. P. 34. London, 1848.

(1) Dr. Copeland: "Dictionary of Practical Medicine." Art. Sleep; vol. iii., part ii., p. 805. London, 1858.

time from severe dysentery, the result of long residence in a tropical climate, and when he came to me was greatly weakened by this malady. The dysentery gradually subsided under treatment, and then I lost sight of him for several months, at the expiration of which he returned, looking worse than ever. He was miserably thin, and so nervous that the sudden closing of the door alarmed him. His memory was effected to a great degree, and he was afraid to speak to his familiar acquaintance, having lost all recollection of their names. There had been no return of the dysentery; he suffered from no pain, but had lost his appetite, and was extremely weak. Having told me all this in reply to my questions, he added—"I am half ashamed to tell you how much I dread night and bed hour, as I have such horrible dreams that for several successive nights I have not gone to bed at all, but slept a little in a chair." In short, this was a well-marked case of "paroniria," which, I may add, was finally cured by a combination of moral and physical remedies, with the necessary medicines. But I have very little doubt that, had this symptom been neglected much longer, the case would suddenly and speedily have passed from the state of *premonitory* into that of *confirmed* insanity. In these cases the hallucinations, as pointed out by Dr. Forbes Winslow, appear to be most vivid at night. "When the patient is placed in a recumbent position, on account, it is conceived, of the mechanical facilities thus afforded for the blood gravitating freely to the head."<sup>(1)</sup>

The first indication in the treatment of morbid dreaming is to remove the primary morbid action or condition, of which disturbed dreaming may be merely a symptom. Thus, for instance, if an unduly acid state of the gastric juice be, as it often is, the cause of uneasy dreaming, we may cure this by alkaline remedies. If, again, we can trace—as, indeed, in most cases of "paroniria" we may—the morbid dreaming to the reflex irritation occasioned by the accumulation of excrementitious matter in the intestinal canal, purgatives should be administered, and in nine out of ten cases of this kind they will remove the cause of complaint. But if the blood be loaded with lithic or lactic acid (for we will generally find that our gouty and rheumatic patients complain of uneasy sleep and distressing dreams, the transmission of these "blood-poisons" through the brain, oftentimes giving rise to nervous irritation and excitement, which is most marked during sleep in the patient's dreams) it will then be necessary, in the first place, to correct this vitiated state of the blood by mineral waters and other appropriate remedies. In a word, to cure morbid dreaming, we must endeavour to put our patient in the most favourable circumstances for sound and healthy sleep, by removing, as far as possible, every source of nervous irritation.

In conclusion, it only remains for me to apologise for the length of this communication, the only excuse I can offer for which is its importance in relation to the study of insanity. I shall be well satisfied, without aspiring to the merit of any very original theory on the subject of dreaming, if the concise view I have afforded of the pathological indications which are furnished by certain forms of dreaming may attract more attention to this question than has hitherto been given to it by medical writers on insanity. The only way to study the diseased actions of the insane mind with advantage is to investigate the healthy actions of the sane mind; and no condition of the mind in health presents so strong an analogy to the condition of the mind in disease as dreaming, and therefore I think that an inquiry into this state is well calculated to throw light on the causes, the nature, and even the treatment of insanity.

## NOTES ON TÆNIA MEDIOCANELLATA (OF KUCHENMEISTER), OR T. INERMIS, BEING ITS FIRST RECORDED OCCURRENCE IN IRELAND.

By Dr. W. FRAZER, M.R.I.A.,

HONORARY MEMBER MEDICAL CHIRURGICAL SOCIETY OF MONTREAL, ETC.

(Read before the Natural History Society of Ireland.)

TAPE-WORM cannot be considered a common affection in Dublin, nor does it seem very prevalent in any part of Ireland. From patients seen in private practice, I have seldom obtained more than three to six specimens each year on an average, though sometimes two or three of these cases will present themselves in rapid succession. The subject of entozoa having recently attracted more of my attention than usual, I became convinced, from investigating the history and symptoms complained of by those individuals I had seen, that there were in Ireland at least two distinct varieties of tape-worm, which I had before always confounded together, and failed to determine their specific characters with that strict carefulness the question demanded, and there were grounds for concluding these would prove to be the common *T. solium*, and its more formidable relation, *T. mediocanellata*, a correct description of which we owe to Kuchenmeister. My surmises respecting the latter worm received ample confirmation a few days since, by a gentleman bringing me the specimen now recorded, which, so far as I can ascertain, is the first recognised example of *T. mediocanellata* of indigenous origin.

The host of this parasite, a gentleman in the prime of life, of robust frame, in perfect health and good condition, consulted me for an eruption of isolated patches of psoriasis scattered over his limbs and body. He also stated that for at least fourteen years past, and possibly for a longer period, he was infested with tape-worm. Its presence caused him great annoyance, as the mature isolated joints of the animal passed from him at irregular intervals, with or without alvine dejections, several of them in succession escaping whilst he was walking about his occupations, or when warm in bed. He had endeavoured to get rid of his unwelcome guest by using the ordinary round of vermifuges, and related his experience with Kosso and Kamela. He preferred the Kamela, its dose being smaller and therefore easier taken, and it had the advantage of being tasteless; he also thought it more effectual, for he succeeded by its means in removing (besides a few small detached fragments) one continuous mass of adhering joints, fifteen feet in length, which he measured after its expulsion, whilst still alive and in motion.

He was anxious to have his pest, thoroughly expelled, and volunteered, with this design, to carry out any reasonable directions. I recommended him to take early in the morning a full dose of castor-oil, and use for that day soft food and soup, &c., to expose the animal more completely to the action of the special vermifuge selected. This consisted of ethereal extract of male fern, which he took, fasting next morning, made into emulsion with yolk of egg, and flavoured by essence of peppermint. It operated briskly, and expelled quite dead a good specimen of *T. mediocanellata*, which measured seven feet in length in one unbroken piece, in addition to some small segments and detached joints belonging to the upper portion of the animal. The head was not obtained, it seldom comes away with the joints after medical treatment, at least far less often than is supposed. As these creatures contract in size considerably after death, its length when living must have reached eight or perhaps nine feet.

The constitutional symptoms caused by this worm were obscure, and insufficient to diagnose its existence, which was best recognised through the constant expulsion of its joints. Close enquiry elicited from the patient that his appetite was irregular, and at times craving, that he felt uneasiness and unpleasant sensations in his left hypochondriac region, and, though more seldom, some pains were experienced in the region of the heart, and extending down the left arm.

The proglottides at the upper portion of the animal are considerably broader than long, the transverse exceeding

ROYAL FREE HOSPITAL.—"At a Special Meeting of the Committee of the Royal Free Hospital, held on the 9th inst., Mr. John Daniel Hill, for many years the Senior House Surgeon, was unanimously appointed one of the Surgeons to the Hospital."

the longitudinal measurement by at least five or six times. Seventeen of these adhering segments occupy a space of one inch. They are easily detached from each other, possessing slight cohesion when compared with the more developed and larger joints. About eight inches lower down fourteen segments were contained within the inch. After this they rapidly became elongated, and assumed the ordinary appearance of common tapeworm, but the ultimate large segments each reached the bulk of 6-10ths of an inch. This striking resemblance of the upper joints of *T. mediocanellata* to the broad shallow joints of the rare *Bothriocephalus* or Russian tapeworm, is a distinctive character of the animal. They are easily separated by observing the different position of the sexual aperture, which is lateral in the *Tæniæ*, and median in *Bothriocephalus*.

To sum up the principal distinctions which separate the two tape-worms found in these countries, the following brief particulars will suffice:—

1st. *T. mediocanellata* is a larger animal; it acquires greater length, is thicker, and its segments broader than the *T. solium*. According to Kuchenmeister, when mature, its average length is at least double that of the latter.

2nd. The proglottides are reproduced with great rapidity, and are remarkable for the freedom with which they escape from the patient: "proglottides permagnæ et pervivaces, sæpissime sponte et sine facibus humanis ex ano demissæ."

3rd. Its head which, as already mentioned, is seldom obtained by medical treatment, is "unarmed." It presents no ring of hooklets, is destitute of rostellum, and studded by four conspicuous dark coloured suckorial disks or acetabula.

4th. The sexual apertures, which are disposed in *T. solium* with considerable regularity on alternate sides of the successive joints, are distributed in *mediocanellata* with exceptional irregularity of arrangement, though always opening on the lateral aspect; they are conspicuous apertures that lead to a complicated, much branched, and peculiarly arranged sexual system. The trivial name of the entozoon is derived from a median thick walled canal or tube, which Kuchenmeister considers continuous, extending from joint to joint.

Experiments carried out by Leuckart, and repeated by Meisner and others, have traced the development of this cestoid animal with much success. When calves are fed with mature joints they soon suffer from severe febrile symptoms, and other evidences of acute disease; after a short time their muscles are found permeated by innumerable minute hydatid cysts, each containing within its cavity heads of cysticerci, resembling in every particular those of the mature worm. Leuckart failed in inoculating the sheep or the pig, and other observers have confirmed his statements.

Professor Aitken at Netley, obtained several specimens of this tape-worm from soldiers, principally from men who had returned from serving at the Cape of Good Hope, and Professor Cobbold remarks in his work on Entozoa that he was surprised on looking over the collection of tape-worms at Middlesex Hospital to find at least half their number referable to this species. I believe it will be found equally common in Ireland, with the ordinary *tænia solium*, though the present instance is the first I am acquainted with in which its characters were recognised, and its claims advocated to be considered a member of our indigenous fauna.

#### CASE OF INTERTHORACIC CYST.

By THOMAS FALCON, M.R.C.S. & L.S.A.

ON the 8th of February last I was called in to visit Mr Jackson, of Pudsey. I found him very weak and emaciated, fainting whilst standing. On the occasion of my first examination of his chest there was no roughness, but an utter absence of the respiratory murmur, both beneath the left clavicle and over the whole anterior surface of the left side of the chest.

The dulness on percussion on that side was greater than I had ever witnessed. The impulse of the heart was felt to the right of its usual anatomical situation, and this abnormal position gradually increased until it was felt beating on the right side of the sternum. The respiratory murmur was distinctly audible over the right side of the chest, both anteriorly and posteriorly, and percussion also indicated a perfectly sound condition of the lung on that side. There was a slight cough, with expectoration of a little mucus. The veins, on the external surface of the left side, were much enlarged, evidently caused by pressure on, and obstructed circulation in, the intercostal and other internal veins. The intercostal spaces on that side were tense and rigid. Dr. Deville, of Leeds, met me in consultation on the case, and he gave it as his opinion, that a tumour had formed in the anterior mediastinum, pushing the heart to the right side, and so compressing the lung as to obstruct the entrance of air anteriorly. The respiratory murmur was indistinctly heard on the posterior part of the affected side. The case could not be one of empyema, as there had been no previous pleuritis; neither was there any protrusion of the intercostal spaces, nor perceptible fluctuation, and the respiratory murmur would have been inaudible posteriorly as well as anteriorly. The sounds were not altered by any change in the position of the body. The most extensive tubercular deposit would not have rendered respiration inaudible on the fore-part of the chest. It could not be hydrothorax, as there had been no previous disease of the heart or lungs, neither was there dyspnoea in lying down. Mr. Jessop, of Leeds was called into the case after my dismissal, and on Saturday, April 27th, punctured the chest, evacuating, as I am informed, some pints of turbid serum. The patient survived the operation till the evening, when he suddenly expired. It would appear, therefore, to have been a large cyst. Are there any instances on record of large interthoracic cysts having been punctured with success?

## Hospital Reports.

### MATER MISERICORDIÆ HOSPITAL.

#### CLINICAL REPORTS BY DR. HAYDEN.

##### HEREDITARY SYPHILIS, WITH A PECULIAR DEVELOPMENT OF THE NAILS AND CUTICLE.

ANNE B—, eight years old, was brought to the hospital by her mother, a respectable-looking woman, and admitted under my care in July, 1866. The mother reported that up to the age of two years the child had been apparently healthy, but *mute*. About that time an eruption appeared on the skin, which has continued up to the present, and latterly become much aggravated. She denies, both for herself and her husband, syphilitic infection, and cutaneous eruption of any kind. The appearance and condition of the child is strikingly peculiar. The head is globular, and the scalp covered with pityriasis; the bridge of the nose depressed; the front teeth crowded, both in the upper and lower jaw, but not numerically in excess; they are disposed somewhat angularly, so that the anterior surface of the incisors have an oblique, or somewhat lateral, instead of a directly forward aspect. The edges of the incisors are remarkably and finely serrated, and the teeth themselves are somewhat dwarfed. The child is partially deaf, and almost completely mute, being able to utter only monosyllables, such as "no," "yes," "babe," &c. She is rather intelligent, but refractory and petulant. The neck, trunk, and arms are covered with a thick layer of furfuraceous scales, and in several situations, where the skin is naturally creased, as on the sides of the neck and palms of the hands, there are deep fissures with thick crusted edges, and angry-looking surfaces. The nails, both of the fingers and toes, have become greatly elongated and thickened, forming rough, irregular masses of a dark-grey colour, resembling piles of scab. The most remarkable of these is

attached to the thumb of the right hand; it is at least half an inch thick, and about equal in length. On this hand (right) the nail of the index-finger alone is unaltered. On the left hand the nails of the thumb and index-finger are unaffected. Of the toes of the left foot, the nails of the fourth and fifth alone are hypertrophied, but on the right foot all are affected except that of the great toe.

Examined microscopically, the deep and soft portion of one of the overgrown nails exhibited only epithelial elements, and a few minute, circular, well-defined, and highly refractile dots, manifestly fatty.

On the palms of the hands and soles of the feet there were large patches of thick-crust scab, the intervening skin being dark red; a similar, but much thicker mass of scab covered the dorsal surface of the right elbow; and a large nodule of scab, of the size of a hazel-nut, existed on the outer surface of the right leg, above the external malleolus. These scabs presented the appearance of rupial growths.

Owing to the state of the feet, and the outgrowth of the nails, the child was compelled to wear boots about two sizes too large for her, and she walked with the feet arched and the toes inverted.

The entire cutaneous surface is rough and tuberculated, and communicates to the hand a sensation similar to that experienced on passing it lightly over a rough-casted wall.

The treatment consisted in a hot-air bath every second day; an ointment, consisting of oxyde of zinc and sulphur ointment in equal proportion, to be rubbed into the surface; occasional washing with glycerine soap, and five drops of Donovan's solution, largely diluted, three times a day after meals; nutritious diet.

July 26th.—Several of the nails have been shed, and replaced by others of a healthy appearance. The fissures in the neck have been healed, and the crusts are scaling away from the hands, feet, and other parts. The child is greatly improved in appearance and in general health.

October 3rd.—Owing to symptoms of gastric irritation, the arsenical solution was discontinued.

On the 10th there were symptoms of laryngitis, but a satisfactory examination of the throat could not be made, owing to the obstinacy of the little patient. Since the 3rd she has been supported almost exclusively upon milk and lime-water. Tongue is now clean and moist; vomiting has ceased, and she is able to take solid food. Crusts are, however, reforming on the hands. Subsequently to this date (13th), and coincidentally with improvement in the condition of the stomach, symptoms of acute broncho-laryngitis were manifested, the treatment of which was greatly embarrassed by the unconquerable obstinacy of the little girl. The treatment was, of necessity, confined to hot vapour inhalations, mercurial inunction, and counter irritation, as the patient would not take either food or medicine.

On the 21st she died of asthenia, and slow asphyxia, which, owing to the existence of extensive bronchial inflammation, did not admit of operative interference.

*Remarks.*—In the fissuring of the hands and neck, the remarkable thickening of the nails, and the scabrous condition of the general surface, this case bore a striking resemblance to "lepra tuberculosa," but from this disease it differed in the absence of great hypertrophy of the skin, and of depilation of the eye-brows and eye-lashes.

At a recent meeting of the Epidemiological Society Dr. Gavan Milroy stated, that within the last four years he had seen four distinct cases (of true leprosy) in Metropolitan Hospitals—three in Guy's Hospital, and one in University College Hospital. He suspects that traces or vestiges of leprosy diathesis are not very unfrequent among us in the United Kingdom.

The condition of the teeth was unmistakeably that described and depicted by Mr. Hutchinson, as characteristic of inherited syphilis. The imperfect development of the head, the mutism, and the partial deafness, as indicating congenital imperfection of the encephalon, likewise pointed in the same direction.

Possibly, therefore, the affection from which this child

suffered was of a mixed character—partly leprosy, and partly syphilitic. The success, as regards the state of the skin, which attended the arsenical and mercurial treatment, may be adduced as collateral evidence in favour of this view.

It is much to be regretted that inflammation of the gastro-pulmonary mucous tract, which I cannot altogether dissociate from the continued use of the arsenical solution, should have prevented the cure of this remarkable case.

## ADELAIDE HOSPITAL.

### CANCER OF THE TONGUE—REMOVED BY LIGATURE AND EXCISION—RECOVERY.

Under the care of Mr. B. WILLS RICHARDSON.

THE following case of cancer of the tongue possesses some interest from the fact of its having afforded grounds for the supposition, that in it were combined the scirrhus and epithelial forms of the disease.

This question of the co-existence of two varieties of cancer in the same tumour or in the same ulcerating growth, although dogmatically assumed by some writers, is, notwithstanding, so full of difficulty, that it would be rash to speak too positively in its favour. The great embarrassment in the matter being, that the cells formed in a supposed mixed cancer, may be cells intermediate in characters to those of different varieties of cancer, and in the existence of which Paget believes.

The chief difficulty, to my mind, in this matter is, that as young epithelial cells have relatively larger nuclei than the adult ones, the young epithelial cancer cells may be similarly endowed, and, consequently, in a specimen having small cells with large nuclei mingled with cells or scales resembling those usually seen in epithelial cancers, the former may be merely the young or immature condition of the adult epithelial cancer cell.

If, as Mr. Paget observes, cells with such large nuclei occur alone in a quickly growing epithelial cancer, they may produce a fallacious appearance of an intermediate form of cancer.

Lebert and Hannover, he reminds us, are satisfied that two kinds of cancer may be mingled in one mass, and that he may have been deceived by a specimen such as they described.

In the case now recorded I also may have been deceived by young epithelial cells, which I may have mistaken for scirrhus cancer cells. They had, however, some characters which induced me to suspect the cancer to have been composed of scirrhus and epithelial cancer.

### CANCER OF THE LEFT SIDE OF THE TONGUE.

(Reported by Sir CHARLES COOTE, Bart.)

T. W., æt. 58, shoemaker, was admitted into the Adelaide Hospital, Dublin, on the 30th of October, 1866, to have a cancer removed from his tongue by Mr. Richardson.

He was a constant attendant at the hospital dispensary for some weeks, and had been, on various occasions, urged by Mr. Richardson to permit the removal of the diseased part while it was limited in extent, there being little doubt of its cancerous nature.

He took a considerable time to "nerve" himself for the operation. But, at last feeling that the disease was enlarging its area, he mustered resolution to submit.

The following history of his case was gathered from him:

He stated that he had been a smoker from his boyhood, and always held the pipe at the left side of his mouth. Four years ago he discovered a small "pimple" on the left side of his tongue, which, not then occasioning annoyance, he refrained from showing it to a surgeon.

In a short time afterwards, ulceration commenced in the site of the "pimple," and as it was accompanied by shooting pains radiating from this part and by foul breath, he was at last induced to seek relief at the dispensary.

Detergent gargles and alterative medicines were ordered, but at the same time an operation was suggested, no doubt

Fig. 1.

MIXED CANCER ?

J. W. . . . ET. 58.

Fig. 2.

CELLS SIMILAR TO THE CELLS FOUND IN EPITHELIAL AND IN SCIRRHUS CANCERS, AND WHICH WERE INTERMINGLED IN THE CANCER REMOVED FROM WELLS' TONGUE.

THE EPITHELIAL CELLS PREDOMINATED IN THE PORTIONS OF THE CANCER EXAMINED. MAGNIFIED 230 DIAMETERS.

having existed as to the malignant nature of the disease. This advice he was then reluctant to follow. The ulcer in the meantime continued to progress, and became ultimately so painful, and caused such annoyance that it forced him to apply for admission into hospital.

He is a thin, weak, sickly-looking man, apparently much exhausted, and suffering from the *malaise* caused by pain, anxiety, and loss of rest. His countenance is extremely anxious. His skin is of a slightly leaden hue, and his pulse ranges from 80 to 100.

He never had suffered from syphilis. There is no albumen in his urine.

At the left side of his tongue, a little anterior to its middle, there is an ulcer about the size of a florin. The base and margin of the ulcer are indurated. The margin is likewise elevated, nodulated, hypertrophied, and partly undermined. The induration does not extend quite to the middle longitudinal line, nor so far backwards as a transverse line that would divide the tongue into an anterior and posterior half. The central or ulcerated part is tolerably deep relatively speaking,—dirty and fetid. Radiating pains shoot from the site of the ulcer. These pains are usually most frequent and intense at night. They are sometimes felt to pass into the left side of lower jaw, and along the left side of the face to the temple. The pains are aggravated by eating, and the movements of the tongue consequent thereon.

Enlarged glands cannot be detected.

The patient having entered the hospital to have the disease removed, the 7th of November was selected for the operation.

The ether-spray was allowed to play upon the tongue until local anaesthesia was produced; the tongue was then seized and drawn forwards by Dr. Walsh, while at the same time Dr. Barton retracted the left cheek. Mr. Richardson then passed a strong, doubled, hempen ligature through the centre of the organ, keeping well clear of the disease. Having removed the curved needle, cut the loop, and separated and differentiated the threads, he tied each half as tightly as possible in notches, (Fig. 1, Plate), which he cut in the tip and at the side, with the intention of preventing the ligatures from slipping towards the ulcer. Mr. Richardson then excised as much of the strangulated part as was possible, without endangering the ligatures, in the expectation that, by so doing, future fetor would be diminished, the bulk of the part to separate being thus lessened.

As far as possible the local effect of the ether was maintained during the whole procedure.

When he was sent to his ward, some blood oozed from the notches, but was quickly arrested under the constant application of ice to the part, and by the use of the following lotion:—

R Acid gallic.	. . . . .	ʒiv.
Glycerini	. . . . .	ʒii.
Tinct. maticoæ	. . . . .	ʒss.
Aquæ ad	. . . . .	ʒx.

Misce. Ft. lotio.

Wine, oz. 6. Essence of meat, &c., middle diet.

Nov. 8th.—Had a good night; pulse 72; right side of tongue somewhat swollen; shining and cedematous looking. This swelling is but trifling, which Mr. Richardson attributes to the use of the ice. There is but little salivation to-day. The anterior part of the strangulated mass is of a dark colour, and gives off great fetor.

Same diet and stimulant, and the following lotion in place of that previously ordered:—

R Lig. potass. permanganat.	. . . . .	ʒiii.
Aquæ destill. ad	. . . . .	ʒviii.

Misce. Ft. lotio.

9th.—Right side of the tongue not so swollen as it was yesterday; pulse 76; fetor not so appreciable. To continue the treatment of yesterday.

10th.—The swelling of the tongue is somewhat less than on the 9th. Slight increase of salivation. Treatment as yesterday.

11th.—Salivation lessened. The tongue pretty much in the same condition as it was on the 10th; pulse 73. Same diet, &c.

15th.—In consequence of the ulcerative process having caused the ligatures to loosen, and as the portion of tongue included within them is very nearly detached, Mr. Richardson removed it in the following manner, with but trivial loss of blood:—Having cut the anterior ligature, its lower end was held secure with an artery forceps, so that when Mr. Richardson drew the ligature forward by the other end, it could be prevented from passing through the hole it occupied. Mr. Richardson next passed the end he held through the loop of a new, doubled ligature, and secured the two together. Then, with the assistance of the old ligature, he drew the new one into the place which it had formerly occupied. Having separated the two halves of the ligature, and tied them tightly, the piece of tongue was thus cut through, and removed.

The same treatment was continued, with the exception of the permanganate of potash lotion, which was replaced by one of carbolic acid, in the form of carbolate of soda, thus:—

R Acidi carbolic	. . . . .	ʒiii.
Bicarb. sodæ	. . . . .	ʒss.
Aquæ ad	. . . . .	ʒx. Misce.

Ft. lotio.

This was found to be an excellent combination, and is, probably, somewhat similar to a solution of carbolate of soda now so extensively used in France for deodorising and antiseptic purposes.

16th.—Rested well; pulse only 68; fetor completely corrected; wound or gap, made by the operation, healing circumferentially, and its surface remarkably clean. Having fancied a mutton chop, he was ordered to have one daily, along with his other diet.

20th.—Is up every day; pulse 72; is improved in appearance, having gained a little flesh; is a better colour, and has lost his dejected countenance. Wound gradually contracting.

It is unnecessary to give any of the remaining daily reports of this case. I may state that the sore gradually healed, leaving a much smaller gap than might have been expected after so great an ablation.

The site of the operation was greatly healed by the first of December, and the man was discharged on the 6th of January following. At this date his countenance was in favourable contrast with the look he had presented on his admission into hospital.

I have been informed that he visited the dispensary upon two occasions since he was discharged; and that there was no appearance of a recurrence observable.

It has been frequently observed to me, while advocating the removal of certain cancers, that, inasmuch as the disease was almost sure to return, why submit the patient to an operation? Grant it. Still it appears to me that, notwithstanding the chances of recurrence are so great, yet much advantage may, in many cases, be derived from their ablation. In the first place, there is the *remote* chance of non-return and cure. Secondly, the less favoured patients are yet subjects of a temporary successful operation, which has relieved them for a time of a painful, and frequently of a foul and harassing disease.

I think we must be constrained to agree with Mr. Paget, that what I shall call the interregnum between the operation and the recurrence should be considered as so much time added to life.

I have already mentioned that I am inclined to believe Wells' case to have been a mixed form of epithelial and scirrhus cancers. Many of the cells represented in the drawing (Fig. 2, Plate) are so like those seen in scirrhus cancer, that I cannot bring myself to consider them to have been young epithelial cancer cells. Besides, if the immature cells of the latter variety of cancer bear a decreasing ratio in size to the increasing enlargement of the growing cell itself, it could scarcely have occurred in Wells' cancer, for it appears to me that many of the nuclei kept pace in rela-

tive growth with that of their containing cell, as also illustrated in this drawing.

Taking this presumed fact into consideration, with the fact of the presence of many caudate and battledoor-shaped cells, so like those seen in scirrhus, I cannot divest myself of the idea but that Wells' tongue cancer was a mingled variety of scirrhus and epithelial cancers. If the observation of Virchow should be confirmed that cancer proper has, in addition to its characteristic elements, also those of an epithelial character, of course there could be no doubt whatever as to the compound nature of Wells' case. I ought here to observe that throughout my observations I have called the malignant disease having epithelial structures, epithelial cancer, believing, with Paget, Rokitsansky, and Virchow, in the close affinity between epithelioma, or carcinoma as it is called by some surgeons—the scirrhus—and the medullary cancers.

It is to be regretted that so many inaccurate representations of the cells seen in cancers have been published, while drawing to scale has been so frequently neglected, that they are almost valueless to the student.

In order to avoid error of delineation as far as possible, I have been in the habit of tracing the cells, as well as some other structures, on prepared box-wood, for the engraver Mr. Oldham, the magnifying power of the glass, with the image apparently thrown upon the wood, having been carefully and accurately ascertained. By so doing, there is less risk of error than if the drawings are made on paper or card, to be subsequently transferred to the wood by the engraver.

Every possessor of a microscope who wishes to have accurate drawings made with the assistance of his magnifying powers and the camera, should ascertain for himself the amplifying power of each objective with the image of the object thrown upon either box-wood, of type depth, or the table itself, the lower surface of the stand and the surface of the table being upon the same level.

These points have been insisted upon by writers, particularly so by Dr. Beale, and should not be neglected, or inaccuracy must be the result.

## Summary of Science.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES R. C. TICHBORNE, F.C.S.L., F.R.G.S.I., &c.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

### DECOMPOSITION OF ACTYLENE BY THE INDUCTION SPARK.

If actylene ( $C^2 H^2$ ), says M. de Wilde, is passed into a dry eudiometer over mercury, on the passage of the spark, a small quantity of carbon is deposited between the wires. If this carbon is knocked off by agitating the eudiometer, and the spark again passed, the same phenomenon takes place. After some time no agitation is necessary, and the decomposition proceeds uninterruptedly. In ten or fifteen hours all the actylene is decomposed; the gas is found to be hydrogen. The actylene should give its volume, but there is always a loss from absorption by the deposited carbon, or other causes. This experiment is important, as illustrative of the splitting up of the hydro-carbon into its elements by the induction spark.—*Bulletin de la Société Chimique de Paris.*

### ON THE USE OF GLYCERINE FOR THE PRESERVATION OF SULPHURETTED HYDROGEN.

I have found, says M. Lepage, a substance which I have employed for three years, and which, without injury to its reactions with metallic salts, preserves sulphuretted hydrogen, and secures to that gas a stability of a considerable duration. To prepare this solution, it is important to provide one's-self with chemically pure glycerine. That called Price's will answer the purpose perfectly, when diluted with its own weight of distilled water. Saturate it with

washed sulphuretted hydrogen gas, using the ordinary apparatus of the laboratories.

Trials have shown me, says M. Lepage, that the mixture of equal parts of distilled water and of glycerine dissolves less of the gas than pure distilled water. My experiments are represented by 100 degrees, which represents the strength of the saturated watery solution. I find that it is only 60 for the glycerine mixture. At the end of six weeks or two months an aqueous solution of sulphuretted hydrogen gas is generally decomposed when kept in a vessel which is frequently opened. On the contrary, under the same conditions, a solution in glycerine, which gave 60 degrees at the time of its preparation, still marks 50 to 56 at the end of six weeks or two months.—*Journal de Pharmacie et de Chimie*, April.

### TEST TO DISTINGUISH BETWEEN CITRIC AND TARTARIC ACIDS.

Messrs. Chapman and Smith, "Laboratory," propose the action of a solution of permanganate of potassium as a distinguishing test between these acids. According to these gentlemen, if a salt of citric acid is added to an alkaline solution of permanganate of potassium, and boiled, the fluid becomes green; but if tartaric acid is substituted for citric, a copious deposit of binoxide of manganese takes place. If this process will determine the adulteration of citric acid with tartaric acid (a common occurrence), Messrs. Chapman and Smith have pointed out a ready test. Care must be taken in both cases to render the solution very strongly alkaline.

### PHYSOSTIGMINE.

C. Hesse has resumed the examination of the poisonous principle contained in the Calabar bean. The freshly prepared alcoholic extract of the bean, is shaken with bicarbonate of soda and ether—very diluted sulphuric acid takes the physostigmine from the ether, and in its turn gives it up when treated with bicarbonate of soda and ether. The ether, on evaporation, leaves the pure alkaloid. It is tasteless, uncrystallisable, capable of enduring for a short time a temperature of  $212^{\circ}$  Fahr., but presently decomposing. It is easily soluble in alcohol, ether, benzol, chloroform, and bisulphide of carbon—difficulty so in water. Its solution is strongly alkaline, and perfectly neutralizes acids. Solutions of its sulphate, chloride, or acetate are tasteless and colourless, become pink on exposure to the air, and are decolourized by reducing agents or animal charcoal.

The colouration, which is intense when the solutions are made alkaline and heated, results from oxidation. Its formula is  $C^{30} H^{21} N^3 O^4$ . A solution of iodine in iodide of potassium, produces with it a crimson precipitate; it is also precipitated by iodide of mercury, iodide of potassium, chloride of gold, chloride of mercury, and tannic acid, but not by chloride of platinum.\*

### TOLUIDINE.

Mr. Alfred Wanklin says that toluidine is absolutely incapable of neutralizing diluted sulphuric acid. This property of toluidine exhibits it in striking contrast with ethylamine and many other organic bases which are known to saturate acids completely.—*Laboratory.*

### CORIAMYRTIN.

This is the name given by J. Riban to a neutral substance obtained from the expressed juice of the *coriaria myrtifolia* (the poisonous myrtle leaved gumach). Coriamyrtin  $C^{29} H^{36} O^{10}$ , is very poisonous. It is solid, white, crystallizes in oblique rhombic prisms, slightly soluble in water, but is very soluble in alcohol or ether. It turns the plane of polarization to the right; does not combine with acids or with chloride of platinum, but contains  $H^2$  replaceable by chlorine or bromine. A trace of this substance moistened with hydriodic acid and evaporated in a water-bath, gives an intense purple-red solution when an alcoholic solution of soda is added.

\* Physostigmine is not to be confounded with eserine, an alkaloid said to be discovered M. Vée, in the Calabar bean. This latter chemist says that eserine is the active product in the bean, and exhibits some specimens in the Paris Exhibition.

## VAPOUR DENSITY OF NITRIC PEROXIDE.

St. Clair, Deville, and Frost, get numbers corresponding to  $\text{NO}_4$  (four volumes), if the formula be doubled and written  $\text{N}_2\text{O}_8$ , then the equivalent volumes must be 8.

## ACETO-SILICIC ANHYDRIDE.

To a mixture of monohydrated acetic, and acetic anhydride, rather less than the proportional quantity of silicic chloride is added. The mixture is boiled as long as hydrochloric acid is evolved; on cooling, the anhydride crystallizes out, and after washing with anhydrous ether, is comparatively pure. It is the first crystallizable organic compound containing silica. It is white, decomposes at about  $165^\circ$  under normal pressure, but may be distilled at a pressure of five or six mil. at  $148^\circ$ . It melts at  $110^\circ$ , its formula being  $\text{SiO}^4 (\text{C}^2 \text{H}^2\text{O})^4$ . It corresponds exactly to Eblemen's ethylic silicate  $\text{Si O}^4 (\text{C}^2 \text{H}^2)^4$ . It is decomposed by water into silica and acetic acid.—*Friedel and Ladenburg.*

## NEW MODE OF PREPARING SULPHUROUS ACID.

M. Stolba (*Journal für Praktische Chemie*) proposes the following mode of preparing this acid:—The sulphates of iron, copper, and lead, calcined with sulphur, disengage sulphurous acid. If the sulphate of iron is employed, a sulphide of iron is left in a desirable state for making sulphuretted hydrogen; twelve parts of dried sulphate of iron are used with five of sulphur. If it is desired to use the residue for making sulphuretted hydrogen, it must be kept well excluded from the air, as it is pyrophoric.

## THE RARER METALS IN MINERAL WATERS.

M. Wartha says that the mineral waters of Ems contain cesium and rubidium, but no thallium.

M. Stolba has also noticed the presence of the first two metals in the mother liquors of nitrate of potash.

## DR. THUDICHUM'S REMARKS ON EXTRACT OF MEAT.

Dr. Thudichum remarked, in his evidence before the Society of Arts, "that extract of meat lacks the essential properties of nutriment. There is a prevalent but erroneous opinion that extracts of meat, particularly that prepared on Dr. Liebig's plan, are nutritious. Tea and coffee will not nourish a man, but both tea and coffee are strong stimulants of the nerves of the heart, and of the brain; and it is likely, I think, that the extracts of meat contain a substance which is something similar in its effects to these stimulants." This is the view, I believe, that Liebig himself takes of his extract. "If the Committee," says the doctor, "desire to know whether I should recommend them to have experiments made upon the extract of meat of Liebig, I must answer that I do not see that any experiments are necessary, unless they wish to open the entire question—What is the sense of our drinking beef-tea, or drinking broth? There is so little nutriment in it, that if you dissolve a teaspoonful of the extract in a cup of water, and drink it, you will not receive so much nutriment as you would derive from a single mouthful of meat." Dr. Thudichum surely does not mean to say that this is Liebig's views. Beef-tea seems to have an important effect, but the effect is not in the sense of nutriment; it is due to the specific effects of certain ingredients, especially creatine, the action of which in some degree resembles that of theobromine. (Theobromine is now shown to be a methyl compound of caffeine, or theine.—*Ed. S.*) Again, in beef-tea are potassium salts, which the body requires for the production of muscular power. Potash is as essentially an element in the chemistry of muscles as in that of the blood. Then, again, there are contained in beef-tea certain acids, of which lactic acid is one, and inosic acid another. If there is an absence of flavour in any kind of meat, lactic acid, if mixed with the gravy during preparation, acts as a substitute, and produces a relishing flavour—the fine flavour of meat; the osmazone which provokes appetite is due in part to the action of lactic acid.

We have to rely on these principles for an explanation of the efficiency of beef-tea, creatine and creatinine, para-

lactic acid, inosic acid, inosite, and potassium salts—which are essential, and which are not, we cannot at present say.

Too strong a solution of extract of meat is as bad as too strong tea or coffee. In answer to the chairman (Right Hon. H. A. Bruce, M.P.), who put the question, that if salt meat being an imperfect food, whether this extract of meat would form a compliment to that? Dr. Thudichum said "that he did not think so, because salt meat has been deprived of a certain amount of albumen." However, the loss of nutritious value from "salting meat is not very great on the whole." As regards the nutritive qualities in meat itself, which the extract does not contain, we find the following list of substances in fresh meat:—First, albumen, then syntonine (fibrin?) When we mince meat and extract the albumen by means of water, there remains this syntonine undissolved, but when mixed with dilute acids it becomes a thin jelly, and is afterwards dissolved. Then myochrome, the colouring contained in the muscles—this is chemically identical with the colouring matter contained in the blood. The use of this latter is to take up oxygen, and to oxidise the noxious products of the spontaneous decay of albumen, giving out carbonic acid. If the meat were shut up close after being killed, it would become putrefied in a few hours. This myochrome is a compound body containing a quantity of iron; it is dissolved with the albumen, and precipitated with it during boiling. Lastly, very little gelatine; then, the constituents as before-mentioned of beef-tea, with a brown syrupy matter, which is not more definable at present. Inosite is a kind of sugar met with in French beans, also contained in muscle and in beef-tea. An occasional product is animal dextrine or heparin, or glycogenic substance from the liver. Sometimes in working half-a-hundred weight of meat, the chemist may get a pound of this matter, at others he may not obtain a trace. When beef-tea is made, the albumen and the myochrome of the meat are made insoluble by boiling; the syntonine also is undissolved. After straining there is nothing left in beef-tea but inosite, creatine, creatinine, lactic, and inosic acids, potassium, salts, brown syrupy matter, and occasionally glycogen, but the latter would be probably absent from the extract prepared by Liebig's company. Of these, from 7 to 10 per cent. of soluble solid matter, from 4 to  $4\frac{1}{2}$  become again insoluble by boiling, so that it is not far wrong to say that only from 3 to  $5\frac{1}{2}$  out of 25, or from one-eighth to one-fifth of the whole of the solid constituents of meat pass into extract or beef-tea. From four-fifths to seven-eighths of the solids are rejected.

## ARSENATE OF ETHYLE.

Mr. Craft causes iodide of ethyle to react upon arsenate of silver, avoiding an excess of the former. The composition is

Its density at  $0^\circ = 1.3264$ , boiling point from  $235^\circ$  to  $238^\circ \text{C}$ .

## ARSENITE OF ETHYLE

Is formed by the action of arsenious acid on silicate of ethyl,

Its density at  $0^\circ = 1.224$ ; boils about  $166^\circ$ . Vapour density corresponds to 2 volumes.

## ON THE INFLUENCE EXERTED BY THE MOVEMENTS OF RESPIRATION ON THE CIRCULATION OF THE BLOOD.

This paper (the Croonian Lecture for 1867) was read by Dr. Burdon Sanderson. As it was a very long one, we will merely attempt to give in a few words the conclusions arrived at by the author. The object was to combat the explanations usually given by physiologists of the mode in which the respiratory movements of the thorax influence the force and frequency of the contractions of the heart. The doctrine usually taught, says Dr. Sanderson, in this and other countries, is stated as follows, in one of the most recent text-books:—"During the act of expiration, the frequency of the pulse is considerably augmented, whilst the line of mean pressure rapidly rises, indicating increased

tension in the arterial walls. . . . . During the act of inspiration, on the contrary, the pulsations become slower, the curves much bolder, and the line of mean pressure gradually falls; for then the blood readily enters the thorax, and as a consequence, the great veins, capillaries, and arterial walls become comparatively flaccid, &c." From numerous experiments, in which the respiratory movements and the variations of pressure in the arteries in the dog, were recorded simultaneously by mechanical means, the author has arrived at an opposite conclusion—viz., that in natural breathing each expansion of the chest is followed by increase of arterial tension, and shortening of the diastolic interval; in other words, that the immediate effect of inspiration is to increase both the force and frequency of the contractions of the heart.

In natural breathing, the influence exercised by the thoracic movements on the heart is entirely mechanical. So long as the respiration is tranquil, variations of air-pressure in the bronchial tubes and vesicles of the lungs do not materially affect the arterial pressure, but violent expiratory movements are accompanied by simultaneous increase of vascular tension.

DECOMPOSITION OF SALTS BY INERT GAS.

Mr. Grenet has discovered the very remarkable fact of the decomposition of a certain number of bodies by the simple passage of a current of inert gas. For example, taking a solution of carbonate of lime, barytes, or potash, through which passes a current of nitrogen, hydrogen or air, the lime, barytes, or potash is precipitated, while the carbonic acid is set free. Sulphydrates, sulphites, acetates, and other salts are decomposed under similar circumstances.

CYANOGEN COMPOUNDS OF MANGANESE.

M. R. Fittig.—Manganic cyanide dissolved in cyanide of potassium, and diluted with alcohol, gives a precipitate of small blue plates, which crystallize from a strong solution of cyanide of potassium in splendid dark-blue transparent square tables. Their formula is  $Mn Cy_2 + 4 K Cy$ . The barta salt separates in blue crystalline groups from a solution of acetate of manganese, mixed with an excess of cyanide of barium. It is insoluble in cold, and decomposed by boiling water.

ANILINE COLOURS FROM PROTEINE COMPOUNDS.

Dr. Erdmann observed upon some roast veal, some red matter, by which he inoculated other favourable substances. The red matter increased. The microscope showed that only the proteine compounds were red. Dr. Erdmann seems to think that this red substance is triphenylosaniline (aniline red).

The following important papers have appeared during the month. In the Proceedings of the Royal Society we have sundry papers connected with the researches brought before the Royal Society, by Mr. Wild, Mr. Siemens, and Prof. Wheatstone. The first of these is *On the Theory of the Maintenance of Electric Currents by Mechanical Work, without the use of Permanent Magnets*, by J. Clark Maxwell. Others by C. Varley, W. Ladd, and Charles Brooke. In the same number a paper *On the Computation of the Lengths of the Waves of Light corresponding to the Lines in the Dispersion-Spectrum, measured by Kirchhoff*, the Astronomer-Royal. M. Scheurer-Kestner, continues his investigations on soda, and communicates to the *Bulletin de la Société Chimique*, some new *Researches on the Preparation of Soda*, by Le Blanc's process. And in the same journal is an interesting paper, by M. Berthelot, *On the Action of Heat upon the Homologues of Benzine*.

In the Journal of the Chemical Society, Messrs. E. Chapman and M. Smith continue their remarks upon *Limited Oxidation*, and propose it as a means of actual analysis. They describe the precautions necessary to procure accurate experiments, and give two illustrations, viz.: Lactate of Baryta, which, on oxidation with chromic acid, yields 7.69 per cent. of carbonic acid (Theory 7.62), so that it is almost as accurate as an analysis with a combustion furnace;

whilst the second case gives, i.e., Diethoxalic acid. They state that by this analysis, any chemist called on to deduce the formula of that body from their experiments, could only arrive at one rational formula, practically identical with that proposed by Frankland and Duppa.

The following are examples of their analyses of diethoxalic acid:—

Carbon existing as Oxtayl, weighed in the form of CO <sub>2</sub> . . . . .	Found.	Theory.
Carbon existing in the propylic form weighed as propionate of baryta	9.10	9.09
Carbon existing in the ethylic form, weighed as acetate of baryta	27.29	27.27
	18.20	18.18

In the same journal we have a paper by Dr. Stenhouse, *On the Preparation of Berberine from Coscinium Fenestratum*. This plant is a large rope vine (order menispermaceæ), and is very abundant in Ceylon and India.

The *Chemical News* (April 5th), contains Dr. Odling's *Classification of native silicates*. And the same journal is publishing an interesting series of papers by D. Forbes, F.R.S., *On application of the Blow-pipe to the Quantitative Determination, or assay of certain metals*. Also an analytical note by Prof. Wöhler *On the Separation of Cadmium from Zinc*. This he effects by adding an excess of tartaric acid, and rendering it alkaline by caustic soda, and then boiling for some hours when the cadmium is deposited. Copper and cadmium the author separate by precipitating the first metal with sulphocyanide of potassium first reducing with sulphurous acid.

In number 2, page 37 of the "Laboratory," under the head of "Royal Society of Edinburgh," will be found a short account by Dr. Crum Brown *On the Application of Mathematics to Chemistry*, in which the author wishes to introduce into the science of chemistry a somewhat similar system of notation to that employed in the higher branches of mathematics. Any paper by W. Crum Brown will be read with interest, but we see many reasons against the introduction of such a system.

(To be continued).

DR. B. W. RICHARDSON  
ON THE INFLUENCE OF EXTREME COLD ON  
THE NERVOUS FUNCTIONS.

On the 7th inst., Dr. Richardson delivered the second of his experimental and practical lectures, which was listened to throughout with close attention by a distinguished audience, and fully equalled the expectations formed by the first lecture, on which we have already furnished some observations. The present lecture detailed the results of Dr. Richardson's investigations into the influence of extreme cold on the nervous functions, which, as he pointed out, are completely corroborated by a similar series of experiments which have been made by Dr. Weir Mitchell, of Philadelphia, the two distinguished physiologists having, without any communication with each other, been engaged on the same subject, and arrived at precisely the same conclusions.

The lecturer commenced by expressing his belief that, when the effects of heat and cold upon the nerves of animals are fully understood, medicine will stand where it never has before. He then went on to show that by means of extreme degrees of cold we can cut off all function. We may isolate and study the phenomena, and may carefully observe them in every stage. We may see the process of extinguishing the function of a part, and notice the phenomena that attend its restoration.

The subject naturally divides itself thus:—

1. The effect of extreme cold on the periphery of a nerve.
2. " " " on a nerve trunk.
3. " " " on the cerebrum.
4. " " " on the cerebellum.
5. " " " on the medulla and spinal cord.

We will give, in as condensed a form as possible, the

results of Dr. Richardson's investigations on each of these divisions of his subject.

1. *The effect of extreme cold on the nervous periphery.*—In the first place cold disturbs the function in different degrees, according to the extent of the freezing and rapidity of the recovery. Here he premised that the freezing point of the body of man is about 16° Fahr. Sometimes the degree of cold may be carried below this without freezing taking place. He has produced a cold of 6° Fahr. But, in these cases, in the act of freezing, the temperature rises to 16°, which may therefore be put down as the freezing point of the human frame, since this phenomenon is exactly analogous to the case of water, which may be cooled below 32° Fahr., but rises to that point in the act of becoming ice. In applying cold to the living tissues, we first of all produce redness, heat, and exalted sensibility, but at 16° Fahr. all these effects are removed, to return on a rise of temperature. This was shown by experiment on the lecturer's arm. The ether spray was directed upon the part, and immediately produced redness, &c. Further application of the spray with a more volatile ether at once blanched the surface. From this experiment Dr. Richardson concludes, that the first effect is on the nervous system, which, on the application of the spray, suffers a momentary vascular dilatation, and so supplies a store of heat. But continuing the application a few seconds, the whole store of heat is taken away, and the tissue completely frozen. Hence, he argued that there is always a stage of congestion before the part frozen; a period exactly corresponding to that of re-action, and which might be termed pre-action. The freezing point differs much in various animals. For instance, in pigeons it is as low as 10° Fahr. We must therefore produce a degree of cold equal to 10° Fahr. before freezing takes place. We may go down to zero in these birds, but there is a rise to 10° in the act of freezing. The blood of pigeons is 10° warmer than that of man. In cold blooded animals it is easier to freeze the part. In frogs it is extremely rapid. This was shown by experiment, the web of a frog's foot being completely blanched by one or two jets of spray.

This fact has an important bearing on cases often seen in practice of extremely low nervous function, and of paralysis. There is in these cases scarcely any nerve force to absorb the cold, and the action is almost immediate on the vessels. There is, then, no pre-action. Dr. Richardson related the case of an old man to whom the spray was applied prior to the extraction of a tooth, and the effect was almost instantly to blanch not only the small part with which the spray came in contact, but the whole jaw. Such a fact as this is of obvious importance in practice.

2. *The effect of cold on the nerve trunk.*—The ulnar nerve is one well adapted for an experiment. On freezing a portion of this, a sensation of pain is produced in the distal direction; yet, volition passes through, and the muscles supplied by it can therefore be used. So in the next stage, when the nerve is, as it were, dead at the point operated on, and still motor power remains. If one or two inches in extent be completely frozen, sensation is extinct below that point in the parts it supplies. If the nerve be exposed, during the process, the stages are first of all vascularity of the nerve. Then, when quite frozen, it assumes a sort of metallic lustre—it looks like sodium very slightly oxydized, or like a freshly broken stick of phosphorus, in which oxidation is only commencing. Frozen nerve is also quite hard, and, on being struck, communicates a kind of vibration. There is not, indeed, any audible sound emitted, but the sensation conveyed to the finger is similar to that when metal is struck.

With respect to electricity, dry nerve, whether alive or dead, is a non-conductor; fresh nerve a most delicate conductor. Freeze the nerve and you find the current still passes. Portions of nerve were here exhibited, and the facts demonstrated by one of Pulvermacher's electrometers.

When, therefore, sensation cannot be transmitted by a nerve, electricity will pass through it.

3. *The effect of cold on the cerebrum.*—In the slightest

stage we see paleness, then congestion; then, on its being frozen, we have whiteness, and on recovery again, congestion or reaction. The cerebrum of an animal may be frozen as hard as a lump of ice, and recovery easily take place; and the experiment may be repeated without injury on the same animal. Dr. Richardson has a pigeon that has been made insensible by freezing the brain forty-six times. On one occasion he had kept it in a state of insensibility for seven hours, and yet it recovered. On freezing the brain of an animal the phenomena that result are, first of all, a peculiar quietness, then follows a little excitement. Continuing the process much excitement is produced—immediately after this stupor and total loss of insensibility; in fact, arrest of everything except breathing. These effects are precisely those of anæsthesia by chloroform, and if two animals were deprived of sensibility, one by the inhalation of chloroform, the other by freezing the brain, it would be impossible, without knowing before hand, to tell which process had been employed on either. Rabbits, in the period of excitement, just before the stupor, often scream in a very peculiar manner. At this point of the lecture a pigeon's brain was frozen, and general anæsthesia produced just as in the case of chloroform. When animals are thus treated in a very low temperature recovery is complete and natural. But in a warm room, when the recovery is very rapid, convulsions often take place. In pigeons may be noticed a peculiar rolling, an attempt to fly or turn over backwards. In rabbits, during rapid recovery, there are often tetanic movements, as if the spinal cord were surcharged with nerve force, and this is the condition the lecturer supposed to exist. It is not a fair experiment to remove the skull from the brain, inasmuch as thereby the effect of pressure in a closed cavity on the return of the circulation is done away with.

When the brain is frozen, large portions of it may be sliced away without producing any effect. The lecturer had sliced off portions of brain down to the corpora striata in rabbits, without meeting those backward and forward movements that have been noticed in birds on injuring these bodies. Dr. Mitchell has seen the phenomena in birds, and therefore there would seem to be some differences between the results of experiments on birds and rabbits.

4. *The effect of cold on the cerebellum.*—In the reaction in birds we get backward motion. In rabbits there is simply a break of co-ordination. But there is none of the rolling movement seen in birds.

5. *The effect of cold on the medulla and spinal chord.*—Partial backward and forward movements were seen by Mitchell in birds. But in rabbits and dogs the respiration is interfered with. Dr. Richardson observes in the earliest stage excited respiration, then contraction of the chest, and, as soon as the medulla is frozen through, death; just as when it is divided. The lungs, when the freezing has been rapid, are left quite blanched—as white as milk; but if the process has been slow, and the respiration some time embarrassed, there may be congestion of the lungs. The heart remains unaffected. Its action is perfect. In fact, at no point of the spinal system can a part be frozen so as to arrest the beat of the heart. Even when the whole cerebro-spinal system is frozen, its function is not disturbed. Yet there is a point in the heart itself on freezing which the organ ceases to act.

If the spinal cord of birds be frozen, we have the backward rolling, the attempts to fly, &c. In rabbits the process produces paralysis, during the reaction convulsions, and with this there is stupor. This is just as when Brown-Séquard produced epilepsy by section. If the reaction be slow we see nothing. If quick, we meet with great convulsion, and sometimes tetanic movements.

The conclusions deduced may be thus briefly epitomised:

(a.) Living nerve freezes at 16° Fahr. The first effect of cold is on the nerve; and in recovery the vessel first recovers. Hence the phenomena of pre-action and re-action.

(b.) Frozen nerve conveys electricity.

(c.) The brain loses no power after the experiment of freezing. In young sucking animals Dr. Richardson has

observed them immediately after play about, recognize the mother, &c., as if nothing had happened. They seem to wake up just as from sleep.

(d.) The cerebellum may be frozen and restored without injury to the animal.

(e.) Complete freezing of the medulla kills by stopping the breath.

(f.) The spinal cord may also be frozen, and recovery take place.

(g.) The phenomena are vascular congestion before the freezing, and a similar condition on recovery—states which might well enough be called *pre-action* and *re-action*.

(h.) It would seem that arrest of function in the brain would determine congestion in the spinal-chord, and *vice versa*.

### THE NEW BRITISH PHARMACOPEIA.

We are at length in a position to lay before our readers some comments on the New British Pharmacopœia. We believe that it seldom happens that a book is introduced to the public with such a flourish of trumpets as has preceded the publication of the present volume. More than a month ago, articles appeared in several of the Medical Journals sounding its praises, long before any one had much opportunity of judging of its intrinsic merits. We should be sorry to detract in any way from the mede of praise due to those who, we feel sure, have used every exertion to make the Pharmacopœia what it ought to be; still, we think, there are some points which we cannot pass over without recording our strongest disapproval of the course adopted by the Council.

We believe that the change in the arrangement of the work will meet with general approbation. The old division into *Materia Medica* and Preparations has been swept away; the alphabetical order has been adopted throughout; in every case where the mode of preparing a drug is inserted, it is given side by side with the general characters and tests, thus obviating the want of unity and great inconvenience attendant on the former method, which necessitated a reference to different parts of the volume for the required information.

The lists of preparations given under each drug have been enlarged and rendered complete in the present edition; and we feel sure that this will be found of great advantage, both to the practitioner and the student endeavouring to master the details of the work.

The Council directs our attention, in the preface, to the objects to be obtained by a British Pharmacopœia. They rightly state, that it is intended to furnish the *Medical Profession and Pharmacist throughout the Empire* with "one uniform standard and guide, whereby the nature and composition of substances to be used may be ascertained and determined." Again, we are told that the object of the Pharmacopœia is "not the selection, but the definition, of remedies which are required to be kept at one safe and uniform standard of strength and composition." We think the objects of the book are here most accurately defined, and we are at a loss to know why the Council thought fit to step beyond their sphere, and to announce in the next breath that they now appended the *doses* of all the more important medicines, and that they adopt this course "in compliance with a *generally* expressed wish."

We would gladly know whose wish this is. Is it that of the Empiric; or that of the Scientific Therapist? We think such a course is utterly wrong in principle, and is calculated to deal a fatal blow to all true

Therapeutics. This Science still lacks that precision which, we trust, it will yet attain; its general laws are few, chiefly owing to the jealousies, prejudices, and "hobbies" of Medical Men; and yet we find the General Council of Medical Education endeavouring to bar its progress, by stepping beyond their powers and functions, and affording facilities for Apothecaries' assistants, and routine practitioners to drug the public. For to whom can the information given be of any practical use? Not to the student, who finds the dose of opium varied as half to two grains, without any indication of the varied actions induced by the drug within the limits set down, and to whom no warning is given as to the danger of administering the drug in this dose to many persons and in many diseases. Nor can it be supposed to be of any service to the well educated practitioner. His study of the action of medicines, unless he be a hopeless empiric, will have taught him, better than the Council can ever do, what the proper dose is; and he will know well how to be guided to the correct dose by the general principles of practical medicine.

Can the Council have had in view that class of men existing in England, and styling themselves in their advertisements in the *Lancet*, *unqualified* assistants? We freely acknowledge that, to persons such as these, it will be a convenience to be put in possession of "the average dose for an adult," as it may fairly be presumed that they are incapable of nicely appreciating the difference in dose to be observed in the treatment of a disease, in its various stages, local peculiarities, and constitutional idiosyncrasies; but we were led to suppose that the Council would do all in their power to extinguish the "unqualified" practitioner, and are sorry to find ourselves mistaken.

This mode of indicating the doses in an apparently authoritative way (for, in a court of justice, and by the ignorant public, it will be looked on as authoritative), can only foster the idea of fixity of dose not warranted by fact, and will certainly lessen the proper stimulus to detailed study of Therapeutics, which, to our knowledge, is so sadly neglected by the student of medicine in the present day.

The Council should consider and remember, that mistakes of this kind will fall, not on them, but on future generations of a defenceless public.

Were it known to the public that men are made surgeons without any knowledge of *Materia Medica* being required of them, and Physicians with but a very imperfect idea of the properties and therapeutic effects of remedies, it would create a sensation that would shake the present system of examinations to its foundations.

It is in the hospital, under the direction of the physician and surgeon, that the student must learn the action and dose of medicines, and not as furnished in the Pharmacopœia, as a premium on ignorance and indolence.

But the doses indicated by the Council are often inconsistent, and in some cases positively erroneous. In support of the first charge, we quote the case of chloroform and its preparations:—The dose of chloroform is stated to be three to ten minims, while that of spirits of chloroform is given as twenty to sixty minims, corresponding to from one to three minims of chloroform, and that of the compound tincture, twenty to sixty minims, corresponding to from two to six minims of chloroform!

As examples of the second error, we may mention that castor, a drug found by Pareira to be inert in doses of two drachms, is ordered in five to ten grain doses; while anti-

monial powder, a preparation at least ten times as active as the original "Dr. James' Powder," is allowed to be given in quantities of from three to ten grains. We feel certain that if the latter dose be administered, it will in every case almost act as an emetic!

But we hasten on to consider the most important alteration in nomenclature made by the Council, concerning which they are silent in the preface, probably because they would find it hard to adduce any good reason for the course adopted. For many years chemists have differed in opinion as to the atomic weight of mercury; for a long time it was set down as 200, and it was believed to form, with oxygen, sulphur, chlorine, &c., two classes of compounds—the one containing an atom of mercury to an atom of oxygen, chlorine, &c.; the other an atom of mercury with two atoms of the metalloid substance, and, in accordance with this view, black oxide of mercury was named the protoxide, and calomel the protochloride, while the red oxide was called the binoxide, and corrosive sublimate the bichloride. These chemical names found their place in the London Pharmacopœia, and were in use throughout England.

But as chemical science developed itself, it became apparent that there were grave objections to looking on calomel as a proto-salt, and to the old atomic weight of mercury.

In the first place, corrosive sublimate possessed properties in every way analogous to those of a protochloride, while calomel was much more akin to a sub-salt; secondly, the atomic volume, deducible by dividing the old atomic weight (200), by the vapour-density, was double that of hydrogen, while, if it be taken as 100, the volume of an atom is the same as that of hydrogen, this being the general rule for simple bodies; lastly, the law of Dulong and Petit required that the atomic weight of mercury be 100, for otherwise the atomic heat (or product of specific heat and atomic weight) would have been 6.38 instead of 3.19, the numbers expressing approximately the atomic heat of the class of metals to which mercury belongs.

This view was adopted in the Dublin Pharmacopœia, of 1850, and in the British Pharmacopœia of 1864, and in accordance therewith calomel was called a subchloride, and corrosive sublimate a chloride.

There are some modern chemists who advocate a return to the old atomic weight of mercury, chiefly from a desire to bring the constitution of corrosive sublimate into accordance with Ampere's law, and this view has been adopted in the new Pharmacopœia.

It will be seen, therefore, that the constitution, and consequently the chemical nomenclature of the mercurial compounds has varied, and even at present does not stand on a very sure foundation, so that we are not secure against some new change in the chemical names.

Now, we fancy that what is required by the Medical Practitioner is a nomenclature that will serve accurately to distinguish compounds of such very different actions and doses as calomel and corrosive sublimate, the red and green iodides, of mercury, where a mistake in the identity of the substance may prove fatal.

To the majority of Medical Practitioners a chemical name, we regret to say, conveys no idea as to the composition of the substance, even when that name is well defined, and we know that this ignorance produces a hopeless perplexity of idea, when the same compound has possessed the very different titles of subchloride, *chloride*, submuriate, muriate, mercurous chloride, and calomel.

In like manner, corrosive sublimate has been termed *chloride*, *bichloride*, muriate, oxymuriate, hydrochlorate, mercuric chloride, and to these the Council has thought well to add another, and they now call it perchloride, while they style calomel the subchloride. We congratulate those gentlemen on having introduced greater confusion than ever into the authoritative codex of the Empire; they have consigned to the position of synonyms the *distinctive* and *unmistakeable* names of calomel and corrosive sublimate, and they have burdened us with a new, dangerous, and utterly inconsistent name. We ask why they did not save themselves the charge of want of unity of design in the nomenclature, by calling the red iodide, the periodide of mercury, and the red oxide, the peroxide. Why is the sulphate not named persulphate, and the nitrate, permirate?

We trust the Profession will mark their disapproval of this inconsistent and uncalled for change, by never making use of the terms subchloride and perchloride.

We greatly fear that the time is not far off when, in a Court of Justice, it may be urged for the defence, that the confusion created by the Council in the nomenclature of the mercurial salts, was a sufficient exculpation for a fatal mistake.

The Council acted with their eyes open, for these points were urged on them by men of undoubted scientific ability, whose suggestions were contemned.

Having, in some respects, spoken so censoriously of the work, we are glad to record our approval of many of the minor changes made. The descriptions given of the drugs are much more accurate; the tables indicating the strengths of the different preparations was a *desideratum*; the introduction of many substances in constant use, not included in the former work, and the care evinced in the preparation of the tables of volumetric solutions, the detailed account of the use of each, and of the equivalent strengths on the metrical scale, will be greeted with satisfaction; and the latter, valued as leading to the future adoption of the metrical system. The work will receive due attention at our hands, and as the consideration of its minute details requires more space and time than we can afford to give it in the course of a single article, we must defer other points to the special notice of the work that will shortly appear in our columns.

Time alone will tell whether the processes given for obtaining the various official preparations are of that practical nature, *capable of being worked on the large scale*, at a moderate cost, so that the manufacturing chemist may find it pay to adopt them, a merit that did not belong to many of those in the Pharmacopœia of 1864.

#### CURRENT LITERATURE.

*The Journal of Anatomy and Physiology.*—The second number of this important half-yearly journal has appeared, and when we say that it equals the promise of the first, we shall be deemed to have given it sufficient praise. Edited by Professors Humphry and Newton, of Cambridge, Professor Turner, of Edinburgh, Professor Wright, of Dublin, and Mr. J. W. Clarke, late Fellow of Trinity College, Cambridge, and now Superintendent of the University Museums of Zoology and Comparative Anatomy, it could not fail to command respect, while the publishers have brought out the work in a form worthy of the renown of the staff. Besides wood-cuts, there are six first-class lithographs in illustration of the papers. There are seventeen

original communications, all by eminent anatomists and physiologists—ample reason this for not attempting to criticise or summarise them. Besides these, we have condensed reports on the progress of anatomy and physiology, and finally, a report on recent Dutch and Scandinavian contributions to these sciences by Dr. W. D. Moore, whose scholarship in these languages is a guarantee of their value. We should be glad to see all these reports occupy more space. They are of very great value.

### MEDICAL EXPERTS.

THE indefatigable Coroner for Middlesex, Dr. LANKESTER, whose election was a great triumph for the Profession, has, in his last report, started a subject of the greatest interest, and one which calls for a careful consideration. Finding too frequently a defect in the medical evidence brought before him, he proposes no less a change in our mode of investigating the causes of death, than the creation of a class of “experts.” He considers that there might very properly be attached to every Coroner’s Court an expert, whose duty it should be to make all necessary post-mortem examinations and chemical analyses, and report to the jury the result of such investigation. It is but just to add that Dr. LANKESTER does not propose to dispense with the evidence of the Medical attendant during life, but he would have his own expert employed in addition. Now, it may be very fairly argued that, in consequence of this saving clause, the Profession would be benefited rather than injured by the adoption of Dr. LANKESTER’S proposal. On the other hand, it may be as plausibly objected that the evidence of such an expert would be apt to over-ride that of the ordinary Medical man, and that the public would be likely to conclude that the Profession, as a body, were unfit for the simplest medico-legal investigations. There are many other arguments, both for and against the proposition, which cannot fail to be noticed. We therefore think the plan should be discussed with the utmost impartiality. The interests of the public, of science, and of the

Profession, are all involved, and inasmuch as considerable difference of opinion, and even conflict of these interests, cannot fail to arise, we propose briefly to state some of the points worthy of the most serious attention, and invite the suggestions of our correspondents on the subject.

In the first place, it is undeniable that a large proportion of practitioners are either unable or unwilling to undertake the laborious and responsible work of post-mortem and chemical investigations in suspicious cases. It is no discredit to the busy practitioner, to acknowledge that he has not had time or opportunity to keep pace with the rapid advances of pathology and chemistry. Neither is it surprising that he should be unwilling to expose himself to the annoyance incidental to the position of an unpractised witness in a Court of Law. Moreover, the payments made for such purposes are so paltry, that to give evidence and make a post-mortem, is mostly an absolute loss; and it is almost undeniable that even in the public ideas on the point, delicate chemical analysis is looked upon as something very different from ordinary medical knowledge. Here, then, at first sight, there really seems a sphere for the expert, if it could only be shown that the cases are numerous enough to keep him employed, and, if the proposal should be adopted, we presume that Dr. LANKESTER would have a post-mortem of nearly every body on which he held an inquest. By so doing, we have little doubt that a large amount of valuable information would be accumulated.

Let us take another point. An expert attached to a Coroner’s Court must obviously not be in private practice, yet he must be a skilled medical man, a first rate pathologist and chemist. These qualifications should secure a proportionate salary. He should, in fact, be paid at least as well as the Coroner himself. But who is to provide the money? Again, Who is to appoint the expert? It would be an absurdity to elect him in the ridiculous manner that the Coroner is now elected. It would be desirable that only the best men should be selected, and they must not be liable to dismissal, or where would their independence be? For this same reason they ought not to be appointed by the Coroner, nor do we think it would be desirable that one should be particularly attached to each Coroner’s Court. Far better would it be for the several Coroner’s jointly to elect the whole number of experts, and each Coroner divide his analyses amongst *all* the experts. For, be it observed, that the evidence of these trained men ought to be strictly impartial. The plan ought to be so worked as to lead to medical evidence being employed in our courts in the character of a quasi-judicial summing-up, rather than in the one-sided manner in which it is now too often exhibited.

At present the very name *expert* is looked upon suspiciously by the public. The most extravagant ideas prevail on the subject, and only the very highest class of men would be able to save the appointment from public distrust. This difficulty would be increased by the fact that, in most cases of foul play, the expert would be the one who first pointed out the nature of the case, and whose evidence would be relied upon by the Crown. He would, therefore, inevitably be looked upon as occupying to some extent the part of public prosecutor, and this, we think, is not the estimate in which a scientific man would prefer to be held. The prejudices of the ignorant are so strong, and so sure to make themselves felt, that it is very doubtful whether a skilled witness, whose evidence must often seal the doom of the prisoner, would not come to be regarded as a sort of professional Jack Ketch.

We have yet another suggestion or two. Are our Coroners likely to appreciate such labours as would be undertaken by these experts? We readily concede that Dr. LANKESTER himself would work his scheme as well as he has done the duties of his coronership. But we cannot, with the present mode of election, always secure a *medical* coroner at all, much less can we hope to have a LANKESTER in every district. We think, therefore, that one of the first steps towards the success of the plan would be to render all who were not legally qualified medical men, ineligible for the office of coroner. In the present state of things, we have grave doubts on the subject, and, considering how medical education is improving, are content to go on for a time in the old way.

In every case of sudden death the medical attendant ought to be summoned and paid for his opinion the usual fee. Should a post-mortem examination, with or without chemical analysis, be required, additional payment adequate to the labour should be given, and in this last case a second skilled medical witness should be associated with the first, and paid separately. The second opinion, so to speak, should be selected jointly by the medical witness and the coroner. There is little doubt that these would almost always call in an expert whose opinion would command respect. We think it not impossible that the mode we have hinted at would be less expensive and equally as efficient as the proposal we have thus far discussed, while it would contribute to a wider spread of medico-legal scientific knowledge, and be more beneficial to the Profession than the creation of a class of experts.

#### THE LONDON COLLEGE OF SURGEONS.

A good deal of conversation in professional circles in London is at this early period being devoted to the approaching elections for the Council. The retiring members are MESSRS. SKEY, KIERNAN, and

WORMALD. They offer themselves for re-election, and consequently we may expect another hot contest, since the reform party in the College is determined to put an end to the routine of re-election as a matter of course.

There can be no doubt that the Fellows will be only exercising their most undoubted rights, should they reject all three of the retiring Councillors, and elect three others to the vacant posts. If we are always to go on re-electing, retirement by rotation becomes a mere farce. It would be better for the opposite extreme to prevail, and no re-election ever take place, though it might be considered that occasional re-election, in exceptional cases, could not possibly be injurious to the College. Yet it ought not to be forgotten that in every instance of a re-election, the turn of the next in order is necessarily postponed, and nothing but the real welfare of the College could reconcile him to the delay.

Mr. PRESCOTT HEWITT is the next in order, and if he will consent to be nominated his name would be a tower of strength to the party of progress. It is said that he does not like to come forward because he disapproves of canvassing, and a candidate who will not canvass may probably be defeated. This we consider to be only a further reason why he should be supported.

If the Fellows of the College possess the independence and the sincere wish for the well-being of their Profession which characterize the mass of medical men, they will not hesitate to place at the head of the poll the distinguished Surgeon who refuses to canvass. Such a course would place all future elections on a better footing, and tend greatly to raise the tone of medical ethics and the value of the College honours.

Next to Mr. HEWITT come the names of Messrs SPENCER SMITH, SIMON, and BOWMAN, all of them deserving the confidence of the Fellows. It is scarcely probable that three new names will, at the next election, be placed on the Council, and yet the movement is so natural, and the probable consequences of such importance to the Profession, that we must be prepared to witness a severe struggle for such a result.

There is another interesting question that has come to the surface through these discussions, viz. —whether it would not be a wise thing to place in the Council a Fellow *by examination*. There is no doubt that the examined Fellows may very easily command large support for such a movement, and as the Senior Fellow, by examination, Mr. LUTHER HOLDEN, is one of the most popular teachers and hospital surgeons in London, his name, if he consented to be a candidate, would alone secure many votes.

It is doubtful, however, whether such a division of strength would not lead to a defeat, in which case it would be to be regretted, for the London College continues to be the most obstructive of all our Corporations, and the one in which a large measure of Reform is most needed. Nothing but fresh blood can ever convert that College into a real benefit to the Profession, from which it derives all its influence. The question on which the Fellows are called upon to give an opinion, is not a personal one. It matters little the names of the select few who

rule in Lincoln's Inn, so long as their governments prove beneficial. But the present rulers have been tried and found wanting; they are unwilling to march with the times, therefore, in the interests of our great profession, and through it of the public, their places must be taken by men who have grown up under new circumstances and expressed new ideas.

#### THE CASE OF MR. T. TENNENT.

A CASE has lately been decided in Chancery which involves so many issues, that we cannot help calling attention to it.

A MR. TENNENT, now of middle age, has, for some time past, been under restraint as a lunatic. His father, since deceased, was the first who had him confined. The exact reasons for his doing so did not transpire in Court, the only fact which came out being that he had fallen in love with a young German lady in the neighbourhood of Deal. After three years at High Beech Asylum he was removed to the Cotton Hill Asylum, which is under the charge of Dr. HEWSON. After this he resided for a time with a medical man near Dover. Lastly, in May, 1863, he went to live with a sister, where he remained, leading, according to some witnesses, a rational life, until February 24, 1866. At this last date he was, "in consequence of an act of violence," sent back to the Cotton Hill Asylum. On the 4th March following Mr. TENNENT's uncle died, leaving him a fortune, and a Commission in Lunacy was immediately issued. Mr. TENNENT was declared by this commission to be of unsound mind. Now comes the curious part of the case.

Last summer Dr. HEWSON took some of the Cotton Hill patients to the sea-side. Mr. TENNENT was one of these; and, while permitted to roam about Scarborough without an attendant, he again fell in love, and this time went so far as, without any one's knowledge, to go through the ceremony of marriage with the lady. Still Mr. TENNENT makes no attempt to escape from the custody of Dr. HEWSON. In fact, the same evening of the ceremony he returned to him as if nothing had occurred. The next stage in this singular case is that the lady invoked the Court of Chancery by a petition praying that the inquisition may be superseded, and Mr. TENNENT in the meantime enjoy more liberty. A medical man was directed to report on his state of mind, and, finding him still insane, the Court refused to interfere.

Now, there are many points in this history which might well give rise to comments of various kinds. With so imperfect a series of facts as transpired in Court, it is scarcely possible to form an opinion as to some of the most interesting problems raised by the case, and, unfortunately, we are not likely to receive much further enlightenment, since a lady who marries a man under such circumstances that he has to return to a medical guardian the same evening, will find it difficult to persuade a jury that she ought not to have entertained some fear as to the validity of the marriage contract. The collateral inquiries as to the proper disposition of the lunatic's property are, of course, of the greatest consequence to his relatives; but, we confess, that in a public point of view, the disposal of his person is of infinitely greater importance. Had the marriage ceremony in question been less precipitate, and attended with other precautions, it would have been invalid.

Yet, in a like case, where no property was at stake, how many marriages may have been effected and never ques-

tioned? and this being so, it may be worth while to inquire whether the "person of unsound mind" might not be better off under the care of a wife, than of guardians appointed by a Commission in Lunacy.

**SANITARY CONDITION OF MANCHESTER.**—The annual report of the Manchester and Salford Sanitary Association, with the remarks of the committee, has lately been published. It shows that the year has been "an unusually sickly one," the death-rate amounting to about 32 in every 1000 of the population. Fever has prevailed to a large extent. The deaths from this disease were 1061, being a larger number than in any previous year since these reports were first issued. It has steadily increased for the last four years; the numbers in 1863 being 399; in 1864, 469; in 1865, 861; and last year, 1061. Nearly the same fatality also has accompanied diarrhoea, the number of deaths from this cause being 1044. There is a difference, however, between these two diseases in one respect, namely, that the fatality of fever has been most marked among the poor, two-fifths of the deaths from this malady being from that class; whereas the deaths from diarrhoea were not so exclusively confined to them, as, out of eleven fatal cases, the poorest classes furnished only one. The inference drawn by the Committee from this fact is, that as a general rule in that neighbourhood, the wretched dwellings of the poor are the haunts of fever, where it takes its rise, and from which it spreads to other parts; and that when public opinion becomes alive to the evil it will insist on those "fever nests being entirely swept away."

## Proceedings of Societies.

### HUNTERIAN SOCIETY.

#### ABSTRACT OF PAPER ON THE PRESENT METHODS OF DIAGNOSIS IN AURAL SURGERY.

By J. HINTON, Aural Surgeon to Guy's Hospital.

THE author first referred to the relations existing between diseases of the ear and other general or local morbid conditions. Respecting these, he remarked that his experience had led him to believe that such relations were remarkably few, diseases of the ear being, in this respect, strikingly unlike those of the eye. Scrofula, gout, and, in a less marked degree, rheumatism, acquired and hereditary syphilis, were enumerated as general causes of ear disease; eczema and psoriasis affected the tympanum, sometimes through the meatus externus. But he had not hitherto discovered any connection between affections of the nervous system of the ear and degenerative changes of the kidney, and other internal organs. There is, however, a peculiar diathesis, with which what we must be still content (or discontent) to call "nervous deafness" co-exists; this is indicated by a peculiar aspect of the countenance, and often by a certain smoothness of the skin. The health may be in all ascertainable respects perfect.

In respect to the means of diagnosis, the author described the means of examining the meatus and membrane, giving the preference to the simple reflection of the day-light by a concave mirror, and the use of the small conical silver, or vulcanite, speculum. Among the tests for the hearing, special importance was attached to the use of the tuning-fork, and some important modes of employing it were referred to. It does not, when placed upon the head, by itself afford a sufficient test of the sensibility of the nerve, since conditions of the tympanum have a great influence on the degree to which it is heard. If, however, it be heard worse on the deaf side, presumably the nerve is implicated; if the disease be tympanic only, the tuning-fork is better heard, very often at least, if not invariably. The reason of this latter fact is that if vibrations existing in the bones of the head are prevented from escaping through the meatus, they are reflected on the labyrinth and heard more

loudly. Thus, if while a tuning-fork vibrates on the head, the meatus be closed, the sound is intensified, and the same result ensues when it is virtually closed by obstruction to the passage of vibrations through the tympanum. Or, if again this intensification of the sound, on closing the meatus be absent, obstructive disease in the tympanum may, with certain qualifications, be inferred. Further still, if a *diminution* of the sound be thus produced, it affords, in the author's opinion, the strongest presumption that the labyrinth is the seat of disease; and especially, that there is a condition of excessive tension, a state analogous to glaucoma of the eye. In many of the instances of "nervous deafness" above referred to, this inverted reaction on closing the meatus exists. By means of a double otoscope also, the relative freedom of the passage of vibrations through the tympanum on each side may be directly tested.

Lastly, the effects of removing the atmospheric pressure from the meatus, by means of the "pneumatic speculum," and those of passing air into the tympanum, were briefly described.

## SURGICAL SOCIETY OF IRELAND.

FRIDAY EVENING, APRIL 26, 1867.

DR. BUTCHER, President of the College, in the chair.

CASE OF FRACTURE OF THE SPINE, IN WHICH THE OPERATION OF TREPHINING WAS PERFORMED.

By DR. HENRY TYRRELL.

SIR,—I propose this evening, with your permission, to lay before the Society the details of a case, in which I performed the operation of trephining the spine for fracture.

I shall not delay the time of the Society by an unnecessary enumeration of the opinions held by the most distinguished surgeons and physiologists on the value of the operation, for already in the pages of the *Dublin Quarterly Journal of Medical Science*, two most learned, instructive, and exhaustive articles have appeared from the pen of my colleague Dr. Robert MacDonnell, in which he has collected from the records of surgery, not only all the cases in which the operation has been performed, but also those in which its performance might have been attended with success.

Patrick Nolan, a labourer, aged 27, was admitted into Jervis-street Hospital on the evening of the 23rd of June, 1866. His lower limbs were paralyzed, he was placed on a water-bed and his urine drawn off by my resident Mr. Daniel O'Sullivan.

I saw him on the following day, Sunday, and found that his lower limbs were paralyzed, that he was unable to pass urine. On turning him on his side in the bed he experienced great pain in the back, and upon examination a visible depression was evident in the lower dorsal region, immediately above the depression the skin was abnormally prominent. He told me, that on Saturday while unloading a corn-ship in the river, he fell down into the hold about twenty-five feet, and that his back struck a beam of timber in the fall. He was rendered insensible by the accident, and upon recovering himself he discovered he was unable to move his legs, he was hauled up on deck by a rope passed under his arms, and brought to hospital on a door. Perceiving I had a fracture of the spine to deal with, I summoned my colleagues in consultation on Monday morning, when, upon a minute examination, the lower limbs were found to have some motor power, for when they were drawn up for him he could press them down slightly. The motor power was better marked in the right than the left leg. Sensibility was normal in both, he could tell when you pinched or touched him, and also distinguish between the application of heat and cold. Reflex action could also be excited. There was no doubt entertained on further examination of the back regarding the injury. There was evidently fracture with displacement forwards and pressure on the cord.

I operated at half-past five o'clock in the ward, the patient being placed on his face, and fully under the influence of chloroform. I followed the same course and used the instruments Dr. MacDonnell did, but I did not find it so easy to use the trephine as my experience in trephining the skull led me to expect. The welling up of blood from the bottom of the wound, and the depth of it, obscured the crown of the instrument so much as to render it necessary to desist after a few turns, and sponge out the wound and examine the bone with your finger-nail to see what progress had been made. However, partly by the trephine and partly with forceps, I safely removed the arches of two vertebrae without inflicting the

slightest injury on the theca. The cord was evidently pressed on before, as it presented a slight convex prominence backwards; the membranes were not tense; the theca was not opened. The superficial wound was five inches long, a small piece of sponge was placed in the centre of the wound, and the ends were brought together by interrupted sutures. He was placed on his side on a water-bed, and supported in that position by large sand-bags. There was no visible improvement in the symptoms after the operation, but, on the other hand, he certainly was nothing the worse of it, although it was necessarily very tedious, occupying about forty minutes. He was ordered to have every third hour during the night a pill containing a grain of ext. belladon. and the same of opium and to take iced-milk for drink.

26th. Nine A.M.—He expresses himself as comfortable, no pain at the seat of operation; pulse 100; urine acid. He is in good spirits; sensibility of limbs good, perhaps he has more motor power, but if so it is very slight. Ordered to take one of the following pills every fourth hour until some decided effect is produced.

R. Ext. Belladon. gr. vi. Pulv. opii gr. vi. Calomel gr. ix. Divide in Pil vi.

Half-past seven P.M.—Passed a good day.

27th. Half-past nine A.M.—He has had a good night's rest, and is very happy and comfortable; asked for beef-tea; pupils not much dilated. Upon the introduction of the catheter he expelled the urine with great force, slightly acid; pulse 98; motor power, perhaps, improved; temperature normal; bowels confined since the accident. He was turned in the bed; ordered the limbs to be shampooed with flannel; the pills to be continued.

Half-past seven P.M.—He passed an easy day; complained of slight pain in the hip on which he lay; a slight change of position relieved him.

28th. Ten A.M.—Passed a good night, had refreshing sleep. He was conscious of the presence of urine in the bladder for the first time, and asked to have it drawn off. Pulse 104; wound was dressed with lint, wet with solution of permanganate of potash; limbs as on yesterday; scrotum slightly puffed. To have an enema of warm water.

Half-past seven P.M.—The bowels acted twice since one o'clock P.M., each time he was conscious of the movement but unable to control it; pulse 104. An angry red spot, the size of crown-piece, has appeared since morning by the side of, but not over, the great trochanter of left side; it is very sore to the touch; there was not the slightest appearance of it in the morning. I applied a lump of ice for a few minutes to the red spot with great ease to the pain. He was placed on his back with a pillow under the knees; he stated his position is most comfortable; no pain in the wound; scrotum not puffed.

29th.—Passed a good night. Bowels acted involuntarily towards morning. Removed the sponge from wound, and dressed it tightly with lint; it looks very healthy, and is suppurating moderately; urine acid; pulse 86; redness of hip not worse. Ordered the following mixture:—

Strichniæ gr. i. spt. vini. Rect. ℥ss. Aq. ad. ℥xii. ℥i. 3 tiis horis. Pulv. opii. gr. i. h. s. Sponged the back and hips with spt. vini camp., and then dusted them with starch; placed him on the right side.

Half-past Seven P.M.—Passed a good day; placed him on his back.

30th.—Had a good night. After the second dose of the strychnine he had violent muscular twitchings. Ordered it to be discontinued. The wound dressed as before with 1 oz. Per. Man. Pot.; got rice and sugar at his request for supper; pulse 88; urine acid. No alteration in the paralytic symptoms.

Half-past seven.—Passed a good day; to take an opiate at night; urine acid; placed on his side.

July 1.—Slept all night; pulse 84; wound suppurating; fluid granulations springing up at either end of it; urine acid; it flows in a full stream, and he can at will propel it with great force. Motor power of legs perceptibly increased; placed on his side.

Half-past seven P.M.—Passed a good day; to have two grains of opium at bed-hour

2nd.—Pulse 84; hips not so red; expulsive power of bladder very good indeed; appetite remarkably good; motor power of legs perceptibly stronger; he can push them from him with considerable force.

Half-past seven.—Passed a good day.

3rd. 10 A.M.—Everything going on well; had a good night. I need not mention anything further regarding his position

in bed, suffice it to say he was changed from his back to his side night and morning. Ordered to take one-sixteenth of a grain of strychnine ter in die.

Half-past seven.—No change during the day.

4th. 10 A.M.—Passed a good night; urine acid; pulse 80; wound healthy, except the inferior part, which is somewhat sloughy. Dressed as usual.

Half-past seven P.M.—Passed a good day. A spot about the size of a half-crown, of a dusky red colour, has appeared. Applied ice to it for two minutes. Galvanism caused a brisk movement of the toes. To continue the strychnine.

5th. 10 A.M.—Passed a good night; pulse 80; urine acid. Temperature of axilla and groin, taken with a centigrade thermometer, normal; hip much better; wound nearly filled with granulations; slough at inferior part not extending.

Half-past seven P.M.—Nothing to note.

6th. 10 A.M.—Passed a good night; pulse 82; urine acid. Remarkable two small white ulcerations, about the size of a sixpence, but oval, on the upper part of the sacrum. As his bowels were not acted on for some days, he was ordered a calomel bolus and an injection of warm water.

Seven P.M.—Bowels acted twice during the day; he was conscious of the movement, but incapable of controlling it; back better. To have a full opiate to restrain the bowels.

7th. Ten A.M.—Passed a good night.

7th. Half-past seven P.M.—Passed a good day.

8th. Ten A.M.—Passed a good night; bowels moved twice; bladder not so tolerant; urine had to be drawn off at three A.M.; redness on right hip very considerable; his limbs are becoming flabby, they however contract vigorously under the influence of galvanism—strychnine to be given four times daily. I do not like his appearance to-day; he seems weaker; the wound is nearly filled with granulations.

Half-past seven P.M.—Passed a tolerably good day; pulse 84; urine acid.

9th. Ten A.M.—Still depressed, although he passed a good night. Ordered six ounces of wine.

Half-past seven P.M.—Passed a very bad day. After morning visit he became very weak, particularly so after the visit of some friends; his sister gave him brandy and egg mixture; he rallied towards evening.

10th. Ten A.M.—Passed a better night; pulse weak, 82; urine acid; his appearance is not so good as it has been, and yet it is hard to assign a reason for the unfavourable change. He eats, drinks, and sleeps sufficiently well, and is in no pain; the paralytic symptoms are slightly worse, as there is less sensibility in the legs, but they contract by galvanism.

Half-past seven P.M.—No change.

11th. Ten A.M.—Passed a good night; is much stronger this morning; pulse 84; urine acid, and passed with force through catheter; wound healing very well; commenced to draw the edges together with sticking-plaster.

Half-past seven P.M.—No change.

12th. Ten A.M.—Passed a good night, but is very weak; left thigh cedematous; pulse 84; urine acid; sweated profusely during the night; he has had occasional twitchings of the hands; no sensation in the legs and thighs. Omit the strychnine.

Half-past seven P.M.—No change.

13th. Although he slept well, still he is worse than on yesterday; cramps continue in the arms; sensibility of lower limbs absent.

Half-past seven P.M.—Stomach very sick during the day; ordered ℥ 2 of creasote every third hour in draught.

14th. Ten A.M.—Stomach relieved; pulse 78; urine acid; he has now incontinence of urine. I don't think he will live for many days.

Half-past seven P.M.—No change.

15th. No change; urine acid; pulse 80.

Half-past seven P.M.—No change.

16th. Ten A.M.—Urine, for the first time since the accident, alkaline; pulse 84; wound not so healthy; bed-sores forming, notwithstanding every precaution.

17th. Urine alkaline; pulse 72.

Half-past seven P.M.—Passed a very bad day.

18th. No change at either visit. He is in no pain.

19th. The left thigh is much swollen and emphysematous; quite resonant on percussion, not discoloured; no sensibility in either limbs; temperature of both the same; pulse 82; urine alkaline and purulent; although the wound is quite filled up with granulations, there is no disposition of the edges to contract.

20th.—Getting gradually worse in every respect.

21st.—Same report.

22nd.—On removing the dressing from the left hip, a gush of air attended with a loud whistling sound escaped, but still the thigh remained swollen and tympanitic.

From this date up to the period of his death, which took place on the 22nd of August, the reports of the daily visits would be of no practical importance; he grew weaker and weaker; the bed-sores spread from day to day, and, at length, from mere exhaustion, he expired without pain just two months after the accident. During the entire treatment I had the benefit of Dr. MacDonnell's constant attendance, and I must here return my thanks to my two resident pupils, Messrs. W. H. Dodd and Daniel O'Sullivan, for the assiduous and enthusiastic manner in which they carried out the treatment. Morning and evening, for two long months in mid-summer, they attended the poor patient, ministered to his every want, and, I am confident, they lengthened his life by several weeks.

Strange to say, I had to leave Dublin the day he died, and Dr. MacDonnell made a careful post-mortem examination. The ham and its membranes were healthy but anæmic; the lungs were healthy, except superiorly, where a few scattered tubercles were found; the abdominal viscera apparently normal, except the kidneys, which were slightly degenerated and fatty; ureters healthy; bladder walls slightly thickened; mucous membrane inflamed; the entire cord was carefully removed at the seat of injury; it was slightly lacerated, and to a very limited extent softened; above and below this part its structure was healthy; portions of it hardened both in spirits and in chromic acid solution, and afterwards stained with the carmine solution was examined; the nuclei of the caudate cells were but feebly coloured, even after remaining some time in the carmine solution, and these caudate cells (in all parts of the cord) contained a little cloud of granular matter, probably fatty; there was no trace of meningitis.

Since the publication of Dr. MacDonnell's memoirs on the subject, the proposal has attracted much attention both in England and America, and I find in the *Boston Medical and Surgical Journal* for January 31st, 1867, a paper by Dr. Daniel W. Cheevers, in which he strongly advocates the operation. Mr. Maunder, of London, has also published a case.

In the London Hospital Reports of last year Mr. Jonathan Hutchinson, in a lecture on Dislocation and Fractures of the Spine, makes the following statement: "That a good many cases recover if put under favourable circumstances and let alone, and that of those which end in death, very rarely, indeed, can it be asserted, after post-mortem examination, that an operation could, by the barest possibility, have done any good. In the great majority, then, since it could have done no good, its effect would have been to increase the patient's sufferings and aggravate his danger." With the latter part of the statement, after reading the reports of Dr. MacDonnell, Dr. Gordon, not to mention the case now brought before the Society, no one, I think, will agree, whatever may be thought of the patients' chance if let alone.

My object, sir, in reading this paper here to-night is to elicit discussion, and to hear expressed the opinions of the members of the Surgical Society of Ireland, on the advisability and prudence of the operation in selected cases, and not upon its imaginary dangers, which I hope the records of the cases operated on here in Dublin will entirely dispel.

The PRESIDENT observed that this very important question had been brought forward in a most satisfactory manner by Dr. Tyrrell. He solicited discussion upon it, and as the question, whether cases of this kind should be meddled with, was one of great importance, he thought it was their duty as practical Surgeons to express their opinions on the case.

Professor HARGRAVE said the case was a very interesting one. The first time the operation of trephining the spinal column was performed was by Mr. Cline, of London, and after that the operation was next done in Mercer's Hospital, by Mr. Reid, of this city. In that case it was an injury to the cervical portion of the column. It appeared to have been a depressed fracture, and when the sunken portion of the bone was raised the man was seized with violent spasmodic convulsions, and it required the assistance of two men to hold him down. The case terminated fatally. He did not object to the operation, but when they came to scrutinize the history of these cases they found that those who were not operated on lived for the same length of time as those who had undergone the operations. Still, that should not prevent them from operating in suitable cases. Mr. Tyrrell mentioned that the spinal cord was lacerated in his case. In trying to arrive at an exact

diagnosis of an injury of this kind they should endeavour to ascertain the way in which the accident occurred. If, for instance, a man were pitched forward on his head, and his neck bent either backward or forward, they might form an idea from that whether the cord was lacerated. If lacerated, there was an end of the case—the man must die. Mr. Tyrrell spoke of the great difficulty in performing the operation because of the hæmorrhage. Now, there was an anatomical arrangement about the spinal cord and cranium which, he thought, was not sufficiently attended to. They had in the library the magnificent plates, by Breschet, of the spinal veins, and he thought they would explain the hæmorrhage in these cases. He thought, as a general rule, that these veins were not taken into account sufficiently by operators. In the present case he thought the healthy condition of the urine for so long a time was a remarkable feature. He was afraid they had a great deal to learn in these cases, but that should not prevent them from performing the operation when they had reason to believe the cord was not lacerated.

Mr. BANON said he was present at this operation, and also at the operation performed sometime previously by Dr. MacDonnell. The great question they had to decide on was this, whether, from what they knew of the effect of operation in these cases, it afforded any chance of rendering the patients' condition better than it would have been if the operation were not performed? He was quite certain that the operation in this case did not do any harm, but he was doubtful whether, in any material point of view, it did good. If they looked at the cases that were recorded of attempts made to relieve the symptoms resulting from an injury of the spine, they would find none recorded that had proved perfectly satisfactory. Now the question was of the utmost importance whether these operations were capable of removing the symptoms. They all knew that in these cases of injuries of the spine, in the great majority of instances the injury takes place in the front of the column, and the pressure is from the front. It had been urged by those who were in favour of the operation that the removal of the posterior portion of the column removed the pressure—that it afforded the spinal column more room by removing the part against which it is supposed the spinal-marrow is pressed. He thought that was very doubtful, and he thought the operation undertaken with that view might probably do more harm than good, although, he repeated, he was quite certain it did not do harm in this case. The removal of a large portion of the spinal column must lead to increased mobility of the part of the column that was the seat of the injury, and in that case the movement of the part might tend to increased injury of the delicate spinal-cord. If they could ascertain that the injury existed only in the posterior portion of the column, in that case it would be a good thing to remove the depressed portion of bone from the spinal-marrow. They would, in such a case, proceed on the same principle as that of removing a depressed portion of the cranium from the brain; but in ordinary cases, when the injury was in front of the vertebra, it was more than doubtful whether operations would remove the symptoms, notwithstanding that Brown-Séguard was in favour of the operation. No doubt the performance of this operation might tend to clear up the subject, and if successful would enable the surgeon to undertake operations of the kind with a well-grounded hope of removing the symptoms.

Dr. STAPLETON said, so far as his opinion went, and he had seen a large number of cases of injury of the spine, it was decidedly against the operation. He had had cases under his care, which were almost hopeless, and yet they recovered. In the first place, in those cases in which there was great displacement, as in the two recent cases under consideration, where there was not only a displacement backwards and forwards, but likewise a twisting, he considered it was of very little use to operate. In the next place, he could not agree with the statement that laying bare the membranes of the spinal-marrow, cutting away the bone piece by piece, and converting a simple into a compound fracture, had no effect on the patient. He thought it had a serious influence. These two cases had what he might call almost super-human attention paid to them; they were watched day and night, and if other non-operated cases were watched as well, the patients would have lived as long. He saw a case in which there was considerable displacement. A man on one of Pickford's vans was going under an arch, an accident occurred, and his body was bent and doubled. The man lay for a long time suffering from the usual symptoms that follow pressure on the spinal cord, and he partially recovered. There was another patient who had suffered an injury of the spinal column, and who lay for months in the

Hospital. Curious to say, his bladder sloughed, and the urine was discharged by the rectum. That man was taken away by his friends to the country, near the place where the late Judge Perrin lived. He recovered. Judge Perrin heard of him, and learning that he used to be carried on a man's back to a place where he was employed to break stones, he got him a small dog-cart, and in this the man used to drive into town once a week. He lived three years after he received the injury, and died of bronchitis. As to hæmorrhage, not only was there bleeding from the veins in these operations, but he had seen smart arterial hæmorrhage. He thought the giving of strychnine or of opium in these cases, was exceedingly bad practice. The proper treatment should be to quiet the patient. If the object were to avoid inflammation, why should strychnine be given, a medicine thought to determine blood to the cord. Opium was also objectionable. Belladonna should be given in these cases to quiet the system. As to galvanism, paralysed muscles will act to one sort of galvanism and not to another. If they applied galvanism in one way to Bell's paralysis, it would act; if in another way, it would not do so, but if applied through the spinal-marrow to the muscles, it would only excite the cord, and thereby do mischief. If there was an injury of the brain and paralysed limbs resulting therefrom, who would think of giving strychnine, or of applying galvanism in the early stages of these cases. Would they not wait until nature had had time to act, and the parts were healed, and then if there was functional and not organic paralysis, it would be the proper time to use strychnine and galvanism.

Dr. MACDONNELL observed—It would be very interesting if they could get accurate details of Mr. Reid's case. In the case Mr. Reid operated upon, Mr. Hargrave said convulsions came on upon raising the depressed portion of the fracture. He was well aware that this was one of the theoretical objections brought against the operation, for it was supposed that the sudden escape of the cerebro-spinal fluid would bring on convulsions. But in no one truthfully recorded case had this phenomenon been observed. It would be, therefore, most interesting if the facts in Dr. Reid's case were put on record and placed side by side with the twenty-seven recorded cases in which there had been an entire absence of any convulsive symptom. It had been supposed that the convulsions occurred from the opening of the theca and the sudden escape of the fluid. Now, physiologists had repeatedly performed experiments on animals where the cord had been opened so high up as to puncture the fourth ventricle, yet no convulsion ensued. He was astonished to find in animals the amount of injury the cord would bear and recover from. At the time Brown-Séguard's pamphlet was published, he repeated all his experiments, and he was astonished to find that in guinea-pigs, rabbits, and other animals, that after the spinal cord had been injured, so as to paralyse the lower limbs—one-half of the spinal cord being divided—they recovered so completely, that, with the exception of a slight halt, one would hardly know that anything had been the matter with them. He thought the great arguments in favour of the operation, which he had warmly advocated, were based on scientific and physiological grounds, and ought to be brought forward now a days more than formerly, for we had new facts to go upon, which the old surgeons had not. At the same time it was surprising, when they looked into the records, how carefully Cline had examined into all these matters, and how accurately he was acquainted with the leading facts of what the spinal-cord would bear. Dr. Banon had suggested that there was no perfect cure effected. Why, when a man's leg was cut off he did not undergo a perfect cure; and in a great and serious operation of this kind they could only expect a partial cure. But a large percentage of the cases operated on had undergone an amount of recovery that was very considerable. In one case, in which he had been able to get some details of the patient, it was true that the man was unable to walk, but he became the father of a family, and lived seventeen years. In the case in which Dr. Gordon operated, the man recovered so much in eight weeks that he was able to walk very well. The details of that case were published at length in the "Medico-Chirurgical Transactions." He went to the iron-works at Inchicore where his (Dr. MacDonnell's) brother was an engineer, and got constructed for the man a low bench and a chair, so that he was enabled to work at his trade. That was a case of recovery so far as life was concerned. It was the first case authentically reported in this country where recovery took place. The cases in America were five out of twenty-five of the whole number of cases where recovery took place, but in these cases the details were not reported with sufficient

accuracy. If, however, they rejected these accounts, they must reject all the cases that came before them through tolerably legitimate channels, the journals published in the locality. Mr. Stapleton spoke of seeing recoveries in almost hopeless cases, and Mr. Hutchinson in his book put forward a number of similar instances. This was the same argument with which he (Dr. MacDonnell) was met by Mr. Barwell in London, when he brought forward Dr. Gordon's case. We have the assertion of Sir Astley Cooper, spoken deliberately, "that if we could save one life in one hundred, it was more than he had yet seen accomplished by surgery." They all knew that Sir Astley Cooper was not a man of wild assertions, and therefore his statement was important as bearing on the question of operations. Moreover, when he was told by Mr. Hutchinson, and his respected colleague, for whose opinion he had the greatest respect, that cases of this kind had recovered without operation, he would point to the museum shelves of Europe. How many cases were to be found of persons whose lives were saved. All knew how rare these cases were, so that the assertion of Sir Astley Cooper stands now as when he made it, that out of one hundred cases it would be a great thing to save one life. Mr. Stapleton objected to the administration of strychnine. Looking at the subject through a scientific and physiological medium, nothing could be more improper than to administer to a patient dying of inflammation any drug which would determine blood towards the organ affected. Belladonna would be the true treatment in such a case. Why then did he suggest to Mr. Tyrrell to give strychnia to the patient in this instance. The spinal cord suffered from three kinds of softening—the red inflammatory softening, the white softening, and that kind of spurious softening, which was the result sometimes of pressure. The latter kind was not an injury from which the spinal cord could not recover. In cases where the spinal-cord was in abeyance simply from pressure, where it had been squeezed, and the blood prevented flowing properly through it, he thought it right to stir it up by bringing back the circulation which had been impeded, and thereby enabling the cord to recover its functions. That which would be wrong, if there were any danger of causing inflammation, became admissible where the acute stage being passed, they had the cord with its functions lying in abeyance, by having been for some time subjected to pressure. When the nerve in the arm was pressed upon during sleep it would cause paralysis of the parts below, yet in time the nerve would recover itself when the pressure was removed; so whenever they had, as in the present case, no evidence of inflammatory action, but the functions of the cord merely in abeyance, as the result of pressure, they had a right to give those remedies which would stir up the cord even at the risk of inflammatory action. It would be seen that belladonna was given at an early period in this case.

Mr. STOKES said it was not his intention either to decry or to advocate the operation, but he desired to make a few observations elicited by the discussion which had taken place. Dr. Banon had urged two very important objections against it, and he was sorry that Dr. MacDonnell had only attempted to answer one of them. Dr. Banon said he had not seen any perfect recovery in cases of this nature, and Dr. MacDonnell replied that no one had seen a perfect recovery after an amputation; but he did not think that was a perfect analogy, for the two operations were perfectly distinct. The other objection he regarded as a more important one, and it was not touched upon at all by Dr. MacDonnell—namely, whether they could, by operating on the spine, remove the anterior pressure which produced the symptoms of paralysis. They knew that there were two kinds of pressure—one anterior and the other posterior; and that it was perfectly easy to remove the posterior pressure while the anterior pressure could not be removed at all. It was this reason which had made Velpeau and Nélaton of Paris speak so strongly against the operation as one that would not produce the benefit expected from it. It had been suggested that pressure anteriorly might occur without causing paralysis—the case of Pot's caries had been adduced as an example—but the difference was that the progress of one was slow, and the cord became as it were acclimatised to the pressure; in the other case, sets in suddenly, and could not be removed. That was the great objection to the operation.

Mr. E. HAMILTON fully coincided with the observations of Mr. Stokes. He had made careful examination of every case of fracture of the spine which came under his observation in Steevens' Hospital, and they were not a few; and in all those cases the appearance which presented itself to his eye was as if the cord were pressed over a bridge rather than any displacement. Anatomy taught them that the cord

lay closer to the body of the vertebræ than the arch of the vertebræ; and a considerable amount of pressure on the arch might exist without affecting the cord. He did not think it a sufficient justification of so serious an operation on the spinal-column to say that it would do no harm. He thought they should have stronger motives than this to induce them to undertake such an operation. Another point to be borne in mind was the great difficulty in diagnosis. Every injury of the cord was not accompanied by depression of the bone. There might be most serious injury caused by concussion or extravasation of blood without injury to the bone. In every case that he had seen, the cord appeared to be stretched over the bridge upon the body of the vertebræ.

Professor HARGRAVE stated that the only thing he knew about Mr. Reid's case was what he had heard from that gentleman himself—namely, that convulsions came on after the depression was removed. The question in these cases was to diagnose, if possible, the condition of the spinal-cord. If lacerated, of course, the operation ought not to be attempted.

Dr. TYRRELL said he was fully compensated for bringing forward the case, by the valuable observations which had fallen from the members of the Society who had spoken. While some agreed with those who said the operation was a good one, and likely to be attended with success, others were doubtful of its efficacy. With respect to the objection urged by Mr. Stokes to the operation as regards the anterior pressure on the spinal-cord, that question had been so fully gone into by Mr. MacDonnell in his late paper, that he would merely refer Mr. Stokes to it for an answer to his objection. As to the observation of Mr. Hamilton, that a serious operation of this nature was not to be justified simply on the ground that it would do no harm, he quite agreed with him in that opinion. The question was whether they might not be enabled by this operation to restore the victim of the accident to comparative health and strength, without running the risk of shortening his life. He thought that in many cases the operation would prove decidedly beneficial, and this at least could be said, that the operation, as done in Dublin and elsewhere, was not attended with the terrible consequences, that had been anticipated by some writers on the subject. The question is one deserving the gravest attention, and must still be considered to be *sub judice*.

The PRESIDENT said that there was one great difficulty experienced in all these cases—there was wanting the power of diagnosis to separate the cases that should be operated on from those that should not. They met with many cases in which persons might suffer a long time from an injury in the lower part of the spine, and ultimately recover and become useful members of society, without having undergone any operation. He had seen many people injured in the lower part of the spine, and their lower limbs partially paralysed, who had yet recovered in the course of eighteen or nineteen weeks. It was difficult to say whether the symptoms arising in these cases were due to effusions of blood, concussion of the spine, or depression of the bone. Because they found a paralysed state of the limbs resulting from the injury, they were not therefore to conclude that depression of the bone existed. He thought the point thrown out by so distinguished an anatomist as Mr. Hamilton, was most important with regard to the position of the spinal-marrow in the canal in which it rests, and how far the pressure was exerted by the depression, or by displacement in front by the body of the bone. They then came back again to the question with regard to the difficulty of diagnosis. In many cases where they least expected it, where there was no depression, they found the spinal-marrow torn across. This condition had been found to exist in cases where no physical sign of it was observable. There were some cases where it might be right to lift up part of the spine, but it was one of the most difficult questions in surgery to decide whether they should interfere with the case or not. The arguments used on both sides were suggestive of a great deal more on the subject, and he quite agreed with Dr. MacDonnell and Dr. Tyrrell, that there was a great deal to be learned with respect to it.

Mr. RICHARDSON stated that the case he was about to read was sent to the Society by Dr. J. Morrison, of Newry, in whose practice it occurred.

#### CASE OF POPLITEAL ANEURISM CURED BY COMPRESSION.

The facts are simply these:—

Michael Larkin, aged 40, a healthy-looking stone-mason, after leaping into a dock about nine feet deep, where he was working, at Belfast, in June last, immediately felt pain and a sensation of stiffness in his right ham, which continued to annoy

him for two or three weeks, when he discovered a tumour about the size of a hazel-nut in the site of the uneasiness. From this time the pain, stiffness, and tumour gradually increased, but not to such an extent as to prevent him from pursuing his daily occupation up to the time of my seeing him—December 20th—when he presented himself for admission into the Newry Hospital.

A large diffuse painful tumour, occupying the upper part of the popliteal space, and extending under the vastus internus, was now plainly discernable; it was fully the size of the largest goose-egg; it pulsed strongly and boundingly, having a clearly-marked systolic bruit. Pressure on the femoral artery in the groin at once stopped the pulsation. The leg and foot were considerably swelled.

The characteristics of aneurism being so abundantly evident, and the system having been tranquillised by rest and the usual preparatory treatment for eight or ten days, Reid's Compressor (3rd series) was applied over the artery in the groin, and kept on at intervals as long as it could be well borne—the time of pressure averaging twelve hours in the twenty-four. The patient was a very intelligent man, and made to comprehend the course of the artery, as well as the necessity of his bearing the instrument as long and frequently as possible. He chiefly conducted the management of it himself, and for eight weeks had the fortitude and good sense to work with it, changing the site of its pressure from the pubis to Scarpa's angle, as the pain and irritation of the integuments prompted. At the end of a fortnight it was quite evident that the parietes of the tumour, at first very thin, were becoming more firm and dense, and that the force of its pulsation had considerably diminished. This improvement went on steadily, though slowly, for eight weeks, at the end of which time the cure was complete, all pulsation having entirely ceased, and the tumour being quite solid.

This case, I think, strongly points out the efficacy of pressure as a remedial agent in aneurism, and also that patience and perseverance in its use may often be required to effect a cure, the way to which for a length of time may seem so slow and unpromising as to lead to the withdrawal of the remedy, which, had it been steadily continued for a longer time, would in all probability have proved effectual.

Dr. Morrison finally states that he saw this man about three days since; he is well and at his work.

#### TREATMENT OF DISEASED BONES OF JOINTS BY THE APPLICATION OF POTASSA C. CALCE.

D. F. KIRKPATRICK spoke as follows:—

At the meeting of this Society on the 15th of February, I had the honour, Sir, of addressing some observations to you upon the subject of a new treatment of diseases of the bones and joints by the deep introduction of the caustic—potassa c. calce; combining its action with incision by means of the knife or by boring with the trochar or drill, so as to reach to and open up the very seat of the disease, into the cancellated structure in the early stage, or into the joint itself in the more advanced period.

In the year 1861, I first made trial of this treatment in cases of caries affecting the flat and superficial bones, and I have since applied the practice in disease of the sternum, scapula, the ribs, and the smaller articulations; also in every case of chronic necrosis that I met with.

In the *Dublin Quarterly Journal* for August, 1865, I brought the subject under the notice of the profession, in a short paper, and recorded some cases successfully treated by this process, and I expressed my conviction that it would be found equally applicable to the larger joints, where disease commences in the cancellated structure of their articulating extremities. I have since, sir, had the satisfaction of realizing the hope then expressed, and I shall now present to the Society a case where a perforation made through the great trochanter into the neck of the femur, was followed by immediate relief to symptoms of morbus coxæ of some months duration.

Through your kind permission I have brought this patient for exhibition after the termination of the meeting, that the members may have an opportunity of examining the case, and of observing the small amount of local irritation and the total absence of all constitutional disturbance that have attended this tunnelling into the neck of the femur.

Thomas Smith, aged 19, admitted into the Hospital of the North Dublin Union on the 1st of last January, with enlarged inguinal glands at the right side. After some days he began to complain more of pain down the thigh and in the knee than at the groin, to which he had at first directed attention, and on examination it was found that he had well-marked symptoms

of morbus coxæ. Notwithstanding treatment by means of iodine, rest, and tonics, the symptoms increased; the thigh became flexed, and any attempt to straighten the limb, abduct it, or give it any extended motion, gave great pain. The usual flattening of the buttock and wasting of the muscles were manifest. Slight rotation of the head of the femur was permitted, showing that the cartilage was not yet affected, but pressure on the head of the bone could not be borne. I therefore came to the conclusion that there was inflammatory softening of the head of the femur, urgently threatening the joint; and, notwithstanding the delicacy of the patient, who was in a very hectic condition, with a pulse at 130, I decided on making a perforation through the great trochanter into the neck of the bone.

On the 22nd of March, having made the surface insensible with the ether spray, I made a circular eschar with the potassa c. calce at the lower part of the trochanter, and cutting through its centre, I used the knife and caustic alternately until I reached the bone, which I attempted to perforate with a small trochar. The compact tissue was firm and resisting, and required some force to make the instrument enter. On the three following days I deepened the canal without causing much pain to the patient. On the night following the operation he got an opiate and slept well. Next day he was not suffering, and said he was better; and on the fourth day he was able to fully extend his leg, and declared he was quite free from all pain; his sleep had returned, and the pulse had fallen to 90. His lameness has since completely left him, and he has been with difficulty kept from taking an imprudent amount of exercise. I fully expected it would have been necessary to carry the boring deeper through the neck of the femur, but such rapid and complete relief followed the formation of the short drain into the trochanter, that I ceased to insinuate the caustic deeper; and when we observe the free communication between the cancelli, as shown in this section of a femur, we can understand how an opening into the base of the neck will act as a drain and relieve all congestion above.

#### NOTES OF A CASE OF POPLITEAL SEROUS CYST.

(By Dr. ZACHARIAH JOHNSON, of Kilkenny.)

The case was admitted under my care in the Kilkenny County Infirmary in May, 1866.

The patient, Martin Murphy, was a healthy young man about 19 or 20 years of age. He had given the affected knee a wrench or strain some months before.

He was sent to me as a case of popliteal aneurism. An examination of the limb decided the point that it was not aneurism.

The tumour was elastic, and fluctuating. There was no pulsation. The tension of the hamstring muscles gave it a lobulated appearance.

I passed in a fine grooved exploring needle under the impression that it might be a large abscess, but, instead of pus, it revealed clear limpid serum, such as flows from a pure uncomplicated hydrocele.

I introduced a trochar, and about ten ounces of clear amber serum flowed away.

It proved to be a single cyst, although the lobulated appearance conveyed the impression beforehand that there were several. The knee at once resumed its natural size. Strapping and bandaging were applied, but the cyst gradually refilled, and tumour became as large as at first.

After some weeks I emptied it again, and now injected it with a solution of tr. of iodine in water, in proportion of ℥iij, ad. ℥viii. This caused some swelling and inflammation, which was subdued by rest and antiphlogistic treatment. It gradually refilled.

In August I emptied it again, and now injected a solution containing nearly one half tr. iodine.

This was followed by inflammation so severe that I was alarmed lest the injection had entered the joint. However, it slowly subsided under antiphlogistic treatment, and he left hospital in November last with the limb restored to its natural size, and no appearance of any tendency to recurrence of the serous effusion.

The case being one of comparatively rare occurrence, and considerable practical importance, I have been induced to contribute these memoranda in the hopes that they might prove interesting to the members of the Surgical Society.

#### FRACTURE IN THE SITE OF NECROSIS.

(By Dr. ANDREW NOLAN, of Wicklow.)

Colia Byrne, a girl of 19, had been affected with necrosis of the thigh for more than a year, when in attempting to show

her father "how well she could walk across the cabin floor" she fell, the bone giving way at the junction of the shaft to the head of the bone about four inches above the knee. She was immediately brought into the infirmary. She was a tall full girl, not much emaciated and tolerably well-nourished considering her situation in life (being the daughter of a labourer); the bone was completely fractured, she complained of little pain, there were three openings along the femur, one on the inner side of the thigh just at the fracture, another in the ham, and another some inches above on the inside, all discharging matter, and from which small pieces of bone had been detached. I placed the limb in a straight position, with a long outside splint from hip to foot, an inside one from groin to the knee, the limb being well padded all round, and as much as possible secured from motion, a piece of oiled-cloth underneath, and no bandages except what were necessary to secure the splints, as the discharge from the openings required daily removal. It is needless to take up the time of the meeting with further details except to say that the limb was kept as immovable as possible, nourishment of all kinds freely given, small pieces of bone from time to time came away, and at the end of seventy-two days from the 16th Dec. to the 26th Feb., the openings had closed, the bone had become consolidated, and she was able to walk out of the hospital with a firm shortened limb.

The second case was that of a young man of 20, the son of remarkably healthy parents, small well to do farmers. He had the dark dirty-looking skin, black hair, and eyes of those in whom you meet the worst forms of scrofula. He had had necrosis of the left tibia for some years, now however healed, and necrosis of the right thigh upwards of a year, when, in attempting to move about, the limb snapped across above the knee as in the former case. I saw him two days after the accident, he was a good deal wasted from the previous discharge and night sweats; there were three openings in the course of the femur, covered with large flabby granulations, one particularly in the ham, all interfering very much with the application of splints. However, by hollowing the latter out over the sores, I was enabled to secure the limb from motion by the splints and padding; the discharge was considerable and required daily removal. I was unable to see the patient oftener than once or twice a-week; however, he was carefully attended to by his mother, he had abundant nourishment, porter, cod-liver oil, &c., supplied him, but it took five months to consolidate the limb, and before all discharge ceased and all sequestræ separated. He has now a useful limb about an inch and a-half shorter than the other, and his general health completely restored.

Though such cases are very likely to occur, I have never seen any recorded; when, therefore, the first case came before me I viewed it with much anxiety. Its successful issue prepared me for the second and much more formidable case. Both show the wonderful recuperative power in the system, but as they entail such prolonged suffering to the patient, and such incessant care and trouble to the surgeon, I think we should in every case be careful to warn our patients of the possibility of such accidents.

#### THE PRESIDENT'S ADDRESS.

GENTLEMEN,—As we have now arrived at the close of our annual session, it becomes my duty, as your President, briefly to review the history of our Society for the past year, and to sum up, as clearly as I can, the main results of your labours during that period.

Whether we regard these results absolutely in themselves, or compare them with those which have been achieved in former sessions, I think we have, upon the whole, good reason to congratulate ourselves on the retrospect.

The interest felt in the welfare of the Society by the members of the profession has continued unabated. The activity and vigour which have eminently marked its operations since its first foundation have suffered no diminution. The spirit of earnest enquiry, of honest search after truth, of simple-minded desire to enlarge the domain of science, by rendering more definite and complete the knowledge already attained, and adding new contributions to the stores already accumulated. This spirit, I am happy to say, has continued to be the motive power, and the guiding principle of our association. To the attainment of these great ends, and to the promotion of these higher purposes, its labours have been directed, and to these supreme objects all minor interests and considerations have been rigidly subordinated.

A healthy vitality pervades every department of its adminis-

tration, and everything promises that its future career will be attended with the same success, and be productive of the same usefulness which have marked its course hitherto. I shall enumerate the communications made and papers read at the several meetings of the Society.

On December 7th Mr. Richardson exhibited a specimen of stricture of the male urethra. The contraction was situated a little anterior to the centre of the canal, and, remarkable to say, there was no other stricture in the canal. Mr. Fleming described the particulars connected with a case of compound dislocation of the astragalus forwards and upwards, unaccompanied by fracture of either tibia or fibula. Also a case of dislocation of the femur on the dorsum of the ileum, occurring in a little girl, aged seven years, and which was reduced by manipulation.

Mr. H. G. Croly made some observations upon congenital luxation of both wrist-joints—viz., luxation of the radius and ulna forwards on the right side, and backwards on the left side; and in the same subject luxation of the head of the right fibula, which he also thought congenital.

Mr. Stapleton described the particulars of a case of dislocation of the thumb reduced by manipulation.

January 4th.—Mr. Edward Hamilton exhibited a cast of a femoral hernia of unusual size, and made some observations on the case of the patient from whom it was taken.

Mr. Fleming exhibited a number of calculi passed by the urethra. He also showed an interesting specimen of "primary" cancer of the kidneys, together with a tumour of the prostate gland.

Dr. Macalister described the particulars regarding some interesting specimens of anomalies of the vascular and muscular systems.

January 18th.—Mr. Wharton exhibited a specimen illustrative of compound comminuted fracture of the bones of the leg near the ankle-joint. There was also dislocation upwards of the four outer tarso-metatarsal bones, at the tarso-metatarsal articulations, and fracture of the same bones near their distal extremities. Primary amputation of the leg was had recourse to.

Dr. H. G. Croly made some practical observations on acute glossitis, illustrated by seven cases.

Dr. Barton made some observations on a case of scald of the glottis.

February 1st.—Dr. Macalister exhibited a large thyroid body, which had a scirrhus appearance and feel. He also exhibited and described some rare muscular abnormalities in the forearm. Mr. Porter exhibited Blandin's knife, and pointed out the advantages of the instrument for slitting the prepuce in acute phymosis. Dr. Leech exhibited a salivary calculus, which he removed from Wharton's duct, and Dr. Macnamara, E. Hamilton, and Mapother, were appointed a committee to examine and report upon its chemical nature.

February 15th.—Dr. Mapother read the report of the committee appointed on the 1st of February to analyze the nature of the salivary calculus presented to the society by Dr. Leech.

Dr. F. Kirkpatrick made some observations in advocacy of the treatment of certain diseases of the bones of joints by the use of potassa c. calce applied to the diseased bones.

Dr. H. G. Croly read the history of a case of acute glossitis.

Mr. Richardson read the report of a case in which the intestines protruded through an abdominal wound, and which ended in recovery. The case occurred in the practice of Dr. Zachariah Johnson of Kilkenny, and the report was sent by him to Dr. Richardson for communication to the Society.

March 1st.—Dr. Davys, of Swords, presented to the Society a specimen of fibro-cellular tumour, which recurred in the site of the cicatrices of former operations, for the removal of similar tumors; the specimen exhibited that evening was the fourth recurrence of the disease in the same situation.

Professor Hargrave exhibited the larynx of a man who died with symptoms of laryngitis, a very fetid abscess existed at the posterior part of the cricoid cartilage, which was stripped of its immediate investments, and seemed to be necrosed. Tracheotomy had been performed and appeared to give some transient relief.

Dr. Edward Hamilton exhibited a stump, the seat of recurrent aneurism after amputation of the thigh for popliteal aneurism.

Mr. Tufnell exhibited a gutta-percha urinal, which he had constructed of peculiar form for a gentleman who was unable to relieve himself without its assistance.

Dr. Fleming exhibited a drawing of an irreducible hernia of a large size; and also a drawing of a large hydrocele of the

neck, which was unconnected with the thyroid gland, was pyriform in shape, very moveable, and contained a large quantity of cholestrine.

March 15th.—Dr. Edward Hamilton gave the particulars of a case in which he performed Symes' operation at the ankle-joint. He exhibited the bones of the tarsus, all of which were diseased.

Mr. Fleming made a communication on the accidents occasioned by the introduction of foreign bodies into the urethra in cases of stricture, and exhibited two specimens to illustrate his subject. He also exhibited three calculi which he removed from the bladder by lithotomy, and detailed the particulars of the cases in which he operated.

Dr. Persse White exhibited the intestines of a man, who died in the Meath Hospital of a bayonet wound, inflicted on the lower part of the abdomen. The intestines were wounded in several places, and signs of peritonitis were evident. Dr. Persse White drew the attention of the Society to the case of a boy, in whom stilticidium urinæ followed the operation of lithotomy, and had persisted for a period of six years.

March 29th.—Dr. Butcher, President of the College, made some observations on the lateral operation of lithotomy, and illustrated his views by the details of a case upon which he had operated that morning. Dr. Banon read the account of a case in which he performed ovariectomy. He likewise exhibited the cyst which was of a very large size.

Dr. John Barker exhibited a large melanotic growth from the neck of a calf, and demonstrated the structure of the tumour under the microscope.

I have just briefly alluded to the headings of these valuable contributions to practical surgery—being fully aware that each paper, with the discussion upon it, is most accurately recorded in THE MEDICAL PRESS AND CIRCULAR for the last six months. To it I refer every gentleman present. The truthfulness and validity of each communication has been most sedulously watched over by your honorary secretaries and by your publication committee, and hence I abstain from any remarks on the important facts brought to light; on conclusions established; ideas suggested; errors corrected; and lines of investigation struck out. There are desiderata still remaining, both in theory and practice, which will afford this Society, and kindred ones, ample work for recurrent sessions. I am sure, gentlemen, you will all unite with me in admitting how deeply we must feel indebted to the two honorary secretaries of this Society for all the trouble they have taken, and the energy they have displayed in promoting our views and securing our success. The one, the learned Professor of the Practice of Medicine in this College, connected with this Society, as one of its honorary secretaries, from its infancy; the other for many years, and taking the place of Bellingham, whose intimate union with its best interests I adverted to on opening this session. The indefatigable exertions of Mr. Richardson I can bear testimony to, from being associated with him on the publication committee for many years. His gentle, forbearing manners, and the acumen which he possesses on all medical subjects, have peculiarly characterized him for the honourable position which he has so truly benefited us by accepting. Having now taken a rapid retrospective glance at our labours during the past session, it only remains for me, in conclusion, to express my heartfelt sense of the high distinction which it has been my lot to attain in occupying this chair, which has been already filled by so many men of whom our profession is justly proud. The recollection of this epoch in my professional life shall be treasured up among my most cherished memories. It will, I trust, bind me more closely to those whose friendship it is my best privilege to enjoy; and it will certainly stimulate me in my efforts to co-operate, to the utmost of my ability, with those who are seeking to maintain and transmit unimpaired the reputation which our great national schools of surgery and medicine have achieved, through the labours of the illustrious men who have departed, and of equally illustrious contemporaries who still continue to adorn and shed a lustre on our ranks.

After the meeting was adjourned by the President, the members examined a patient of Dr. Kirkpatrick's, into whose great trochanter some potassa c. calce had been inserted by that gentleman. The boy walked into the room, and did not appear to suffer any inconvenience from the sinus made by the caustic.

#### TREPHINGING THE SPINE.

LETTER FROM PROFESSOR HARGRAVE TO MR. RICHARDSON  
REGARDING MR. REID'S CASE.

"Upper Mount-street, May 4th, 1867.

"DEAR RICHARDSON,—In reference to the statement which I

made at the Surgical Society, held April 26th, on the operation performed by Mr. Reid in Mercer's Hospital, for trephining the spine, which was, to a certain degree, doubted by some of the members,

"I have called since that date on Mr. Reid, who has furnished me with the following facts in support of my statement:—

"The patient was a Swedish sailor, who, in some drunken brawl on George's-quay, or in some of the adjoining streets in this city, fell from a considerable height on the back of his head and neck, and was brought into Mercer's Hospital paralyzed in the extremities. As he lay on his back the slightest rotatory motion of his head to either side threw his whole frame into strong convulsions; on examination, a depression in the lower part of the cervical spine was well-marked.

"Mr. Reid diagnosed a depressed fracture of the 3rd or 4th cervical processes; he decided on operating, so as to elevate or remove the depressed portions of bone; when they were exposed it was found that the transverse processes of the 4th cervical vertebra were driven into the spinal canal. On the endeavour to elevate and remove them the spinal-cord was occasionally compressed, instantly followed by violent spasms of the entire body, alone controlled by the presence of two strong assistants; the depressed portions of bone were elevated and removed, the wound dressed, and the patient placed in his bed.

"The good result of the operation was immediate in one respect—namely, the patient could rotate his head freely from side to side, without any spasm or convulsion being followed by that motion; he survived the operation in comfort for six days, and then expired. As I observed, when alluding to this case, Mr. Cline, of Guy's Hospital, was the first to perform this operation of trephining the spine; and my friend, Mr. Reid, the second, as far as my knowledge of the history of my profession enables me to decide. This case was treated in Mercer's Hospital about forty years since, and has lost none of its interest; no doubt but the admission of the patient can be found in the records of that institution. No post-mortem was made. I may add that, many years since, I had under my care Mons. Beaujean, a professor of gymnastics, who, in performing the feat of what was called "the pole," was flung from a height of ten feet, with great violence, on his occiput, and was taken up paralyzed in his entire system, except the head and face; he survived the accident seven or eight days. The post-mortem examination exhibited partial luxation of the bodies of the 5th and 6th cervical vertebræ, the oblique processes of the 6th fractured, and the cord corresponding to the lesion was lacerated perpendicularly to the size of a split-pea.

"It affords me much satisfaction to be able to record this very interesting case of Mr. Reid's, and to observe that he was the first in Ireland to perform this operation, which, in one respect, conduced so much to the comfort of the patient.—Believe me, yours affectionately,

WILLIAM HARGRAVE.

"B. Wills Richardson, Esq.,  
"Hon. Surg. Sec. to the Surgical Society."

#### OBITUARY NOTICE.

##### M. JOBERT.

WE have briefly to notice that the funeral solemnities of this renowned surgeon were celebrated at the Madeleine Church, in Paris, on the 26th of last month. As is usual with men of eminence in France, a large concourse followed in the procession, composed, amongst others, of the representatives of all the learned societies to which M. Jobert belonged. Besides the religious services, it is customary for friends of the deceased to pronounce addresses over the remains. This was done by several of the members of the learned societies who were present, and who paid a high tribute to his attainments and his memory. He had achieved a reputation from a comparatively humble sphere, but, notwithstanding his celebrity, he appears to have been subject to habitual depression, even melancholy, which eventually ended in mental disorder, and he spent the last two years of his life in the private asylum of Dr. Blanche, who was formerly his pupil, and who paid him the kindest attention down to the hour of his death.

## Medical News.

### ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—

The following gentlemen passed their final examinations, and were admitted Licentiates of the College, during the recent sittings of the Examiners:—

Andrew David Barrie, Madras; Titus Cumins Crooker, Canada West; William Alexander Finlay, Edinburgh; James Gairdner, Crieff; Walter Bayne Geikie, Edinburgh; Edward Heyns, Co. Clare; Charles Holden, New Brunswick; William Hunter, Kilrea, Ireland; Alfred William Lupton, Wakefield; James M'Iroy, Bushmills, Ireland; Robert Shand Turner, Banffshire.

### FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.

—During the recent sittings of the Examiners, the following gentlemen passed the final examination of the Faculty:—

James Conolly, M.D., Galway; R. F. W. E. Goedicke, London; James W. C. Grant, Aberdeen; William Jameson, Manchester; Henry Knowles, London; James Oglvie, Glasgow; Thomas K. Salter, London; John Vance, London.

The following passed the first professional examination:—

William J. W. Cetchell, John Mackinlay, Alexander C. Moffat, and James Robertson, of Glasgow; Samuel A. Payne, of Manchester.

The following gentlemen passed the final examination for the Double Qualification granted conjointly with the Royal College of Physicians of Edinburgh:—

William H. Armitage, Glasgow; William H. Belcher, Cork; William Belcher, Dublin; B. R. Boast, Glasgow; Edward Curse, Edinburgh; Joseph H. Hill, Glasgow; Edwin Hollings, Glasgow; John Kershaw, Manchester; Hugh J. Lloyd, Glasgow; William L. Muir, Glasgow; Thomas Tinley, Glasgow; Henry E. Trestrail, Glasgow.

The following passed the first examination for the Double Qualification:—

Thomas Richmond, George W. Johnstone, Edward P. Edwards, Duncan C. Milboy, James G. Beasley, James P. Cunliffe, Bernard W. Wellings, Adam Wilson, Richard Lougher, William Stephen, James Kelly, and George R. Atkinson, of Glasgow; James H. Fletcher, of Manchester.

**APOTHECARIES' HALL, LONDON.**—On April 25th, 1867, the following Licentiates were admitted:—

Edward Dyer, Clerkenwell; William Hubert Holmes, Cork; Thomas Frederick Hopgood, Chipping Norton; Ernest George Thomas Llewellyn, Wetheridge; Thomas Richardson Loy, Stokeby, Yorkshire; George Pavey, Edmonton; William Edmond Richardson, Rochdale.

At the same Court, the following passed the first examination:—

Henry Arthur Allbutt.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH: DOUBLE QUALIFICATION.**—During the recent sittings of the Examiners, the following gentlemen passed their final examinations and were admitted L.R.C.P. and L.R.C.S. Edin:—

John Alexander, Caithness-shire; William Munden Allan, Newfoundland; Alfred Bennison Atheron, New Brunswick; Eli James Barrick, Canada West; John Brosnan, Kerry; Samuel Brown, Jamaica; John Cascarden, Ballintra, Ireland; Richard Vooght Clampitt, Devon; John Kerr Davidson, Caithness-shire; William Easby, Durham; David Edgar Jones, Cardiganshire; John Leader, Co. Cork; John M'Rae, Ross-shire; Robert Stevenson, Kilwinning; Thomas Todhunter, Whitehaven; Francis Vacher, London; Thomas Richard Vaux Woodfield, Sunderland.

The following also passed their first professional examinations:—

John Dewar, Glasgow; William Mackie, Glasgow; John Gillies, Skye; Enoch Davies, South Wales; John Sayer Bridgford, London; William John Cuthbert Ward, Lancaster, Durham; George Watters, Caithness; William Gowans, Prestonkirk; David James Hamilton, Falkirk; William John Campbell, Poonagh.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen were admitted Members of the College, on May 7th:—

Reginald Bayley, Nailsea, Bristol; John Gulley Blackley, Manchester; Samuel Hamilton Cartwright, Old Burlington-street; Charles William Chapman, Dalston; Edward Fluder Chinery, Lynton, Hants; Ernest Thomson Raimbach Evans, Jersey; Benjamin Franklin, Liverpool; Joseph Gabe, Merthyr Tydfil; Henry Walter Gostling, Oakley, near Bedford; James Robert Haynes, Clipstone-street; Thomas Frederick Hopgood, L.S.A., Chipping Norton; Henry Edward Juler, Shepherd's Bush; Walter Maine, Barnstaple, Devon; Charles Henry Newstead, Royal General Dispensary; James Cornelius O'Grady, Bombay; Frederick Morrish Pierce, Higher Broughton; Thomas Henry Pinder, Whitley; Robert Longuet Sheffield, L.S.A., Mile End Road; Frederic Walter Smith, Brenchley, Kent; James Walker, Leeds; George Thomas Willan, Bourne, Lincolnshire.

On May 8th—

James Brown, Dudley Port; Louis Charles Achille Carre, Bath; Henry Case, Box Moor; Henry Cheeman, Lewes, Sussex; Matthew Owen Coleman, Surbiton; Alexander Paul Fiddiss, Bridgend, Glamorganshire; David Owen Fountain, Stoke Hammond, Bucks; Charles Crindrod, Liverpool; Thomas Richardson Loy, L.S.A., Stokeley, Yorkshire; Henry Widinham Maunsell, Dublin; Samuel Edwin Solly,

Savile Row; Alfred Steward, Wolverhampton; George Stokell, L.R.C.P. Lond. & Edin., L.S.A., Hobart Town; John James Swindell, Finchley; Joseph Wharton, Oldham; John Greaves Wiseman, Ossett, Yorkshire; Edwin Woodward, Birmingham.

On May 9th—

Messrs. William Edward Stevens, Pewsey, Wiltshire; Charles Lewis, Blackheath; and James Thorne, Jersey, students of Guy's Hospital; Thomas Flower, Codford, St. Peter, Wiltshire; and William Wilberforce Smith, Havrstock-hill, of the Middlesex Hospital; Henry Mann Fothergill, Newcastle-on-Tyne; and Walter William Spencer, Liverpool, of the Newcastle School; John Erp Burton, Lic. Fac. Phys. and Surg., Glasgow, Liverpool, of the Glasgow School; Richard Albert Shipman Prosser, Birmingham; William Edmund Cant, Colchester, of St. George's Hospital; John Williams Pring, Ffestiniog, North Wales, of the Dublin School; Charles Wilson Milne, Wandsworth, of St. Thomas's Hospital; George Fisher, Baytry, Yorkshire, of the Leeds School; and Oliver Penfold, Blackmoor-street, of King's College. It is stated that only seven candidates out of the 59 who presented themselves for examination failed to acquit themselves to the satisfaction of the Court, and were consequently referred to their hospital studies for the period of six months.

**ROYAL INSTITUTION OF GREAT BRITAIN.**—At the last General Monthly Meeting, Sir Henry Holland, Bart., M.D., D.C.L., F.R.S. President in the Chair, Professors John Tyndall, Esq., LL.D., F.R.S., Edward Frankland, Esq., Ph. D., F.R.S., were re-elected as Professors of Natural Philosophy and Chemistry. The Presents received since the last Meeting were laid on the table, and the thanks of the Members returned for the same.

## NOTICES TO CORRESPONDENTS.

### THE ADULTERATION OF HONEY WITH SUGAR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having recently purchased a quantity of honey, from which the comb (now in a much broken state) has not been thoroughly removed, will you inform me how I can ascertain if it has been adulterated with sugar. It does not contain starch.—I am, Sir, A. H.

[The correct modes of determining this point, viz.—1. By its action upon Fehling's solution; 2. By the rotatory power before and after inversion—are too difficult and complicated to be of any use except in the hands of an experienced chemist. However, an idea may be found by pressing a small quantity of the suspected honey between two pieces of glass, and examining it with the microscope. The crystals of dextroglucose (the main constituent of honey) form opaque, granular, hemispherical, or cauliflower-shaped masses, whilst cane-sugar forms well-defined monoclinic prisms, with hemihedral faces—a large form of which is seen in sugar-candy. It should be borne in mind, however, that "cane-sugar," in small quantities, is a normal constituent of new honey, but is gradually converted by keeping into dextroglucose, &c. If the point to be determined is of importance, "A. H." should have the honey examined by an Analytical Chemist.—Ed. M. P. & C.]

## Births, Marriages, and Deaths.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

MARTIN.—On the 21st ult., at Crawley, the wife of T. H. Martin, M.R.C.S.E., of a daughter.

PEARSE.—On the 29th ult., at Botesdale, the wife of Arthur Pearse, M.D., of a daughter.

ALDERSON.—On the 2nd inst., the wife of Frederick H. Alderson, M.R.C.S.E., of Grove-terrace, The Grove, Hammersmith, of a daughter.

BARNETT.—On the 2nd inst., the wife of Dr. H. C. Barnett, of Milford, of a son.

### MARRIAGES.

CAMPBELL, SCROGGIE.—On the 24th ult., at Beechwood House, Laurencekirk, Alex. C. Campbell, M.B., L.R.C.S.E., &c., of Laurencekirk, to Agnes, second daughter of the late David Scroggie, Esq.

M'COY, RUSSELL.—On the 30th ult., at the Parish Church, Westbury-on-Trym, Robert W. M' Coy, L.K.Q.C.P., &c., of York, Western Australia, to Geraldine Jane Loftus, second daughter of the late Christopher Russell, M.D., of Enniskerry, Co. Wicklow.

DWANE, CLANCY.—On the 30th ult., at the Church of S.S. Peter and Paul, Cork, by the Very Rev. T. W. Croke, D.D., P.P., V.G., Doneraile, assisted by the Rev. W. Fitzgerald, C.C., Dr. Thomas M. Dwane, L.R.C.S.I., Cloyne, to Delia, daughter of the late Samuel Clancy, Esq., Charleville, and niece of Timothy Murphy, Esq., of Amiens-street, Dublin.

### DEATHS.

LAWTON.—On the 7th ult., at his residence, St. Philip's-road, Sheffield, S. Lawton, M.R.C.S.E.

WEST.—On the 1st instant, at Alford, Lincolnshire, Bennet Langton, the youngest child of Dr. R. Uvedale West, aged 14 years.

WOOD.—On the 1st instant, at Penze, Surrey, after four weeks' acute suffering, Reginald, the youngest son of Charles G. Wood, Surgeon, aged 4 years.

WILLIAMS.—On the 3rd instant, John Williams, Esq., of Stanthill, Dursley, Gloucestershire, and of Fynnon-road, Peterstone, Glamorganshire, aged 67.

STADDON.—On the 4th instant, at Friar's-road, Ipswich, Lizzie Alice, the only daughter of J. H. Staddon, L.R.C.P. Ed., M.R.C.S.E., aged 1 year.

Lectures.

THE METROPOLITAN WATER SUPPLY.

A DISCOURSE

DELIVERED AT THE

ROYAL INSTITUTION OF GREAT BRITAIN,

MARCH 29TH, 1867.

By Dr. E. FRANKLAND, F.R.S.

PROFESSOR OF CHEMISTRY IN THE ROYAL INSTITUTION.

ANOTHER attack of the most terrible epidemic to which modern London is subject has once more called earnest attention to the serious defects of the Metropolitan Water Supply. The origin and spread of cholera is confessedly still involved in much obscurity, but the experience which we have derived from four visitations leads irresistibly to the conclusion that, whilst no successful barriers have been devised against the introduction of the disease into this or any other country, cholera can never establish itself as an epidemic unless the water supply of a community be tainted with organic impurity; thus Manchester suffered fearfully from cholera in 1832 and in 1849, whilst supplied with impure water; but after the introduction of pure water from the Derbyshire Hills, the return of the disease in 1854, and again last year, manifested itself in Manchester by a few sporadic cases only, although in other respects Manchester is one of the most unhealthy towns in the United Kingdom.

The violence of the epidemic, as Dr. Farr has shown, exhibits also a close relation to the degree of sewage contamination of the water supply. Thus he has demonstrated that in the visitation of 1849 that portion of the metropolitan population which was supplied by water taken from the Thames at Kew, suffered a mortality from cholera of 8 in 10,000. Of every 10,000 people supplied with water taken from the river at Hammersmith, 17 died. Of the inhabitants in Belgravia, St. George's, Hanover-square, Chelsea, and Westminster, supplied with water taken below Chelsea Hospital, 47 in 10,000 died. Whilst the populations drawing their supply still lower down—viz., at Battersea, and between Hungerford and Waterloo Bridges, where the river was still more foul, suffered to the extent of 163 in 10,000. In the year 1854 one-half of this latter district was supplied by water taken above Teddington Lock, and the deaths fell to 87—little more than one-half; whilst last year, when the whole supply was drawn above Teddington Lock, the loss of life was only 8 in 10,000.

The water withdrawn from the Thames is now all taken above Teddington Lock, and its filtration before distribution is rendered compulsory by the Metropolitan Water Act of 1852. The wisdom of thus withdrawing the water at a higher point, and of enforcing its filtration, is evidenced by the comparatively slight mortality from cholera last year in those districts supplied with Thames water. Far different, according to the Registrar-General, was the fate of that portion of the metropolis which had the misfortune to be supplied from a reservoir at Old Ford, belonging to the East London Water Company. The suddenness and virulence of the outbreak of cholera in the East of London last summer at once aroused the suspicions of the Registrar-General, who requested me to make an immediate investigation into the East London Water Company's supply. I found the reservoirs at Old Ford to be situated close to the River Lea, which is there little better than an open sewer. The chief reservoir is also sunk sixteen feet beneath the low ground, which is there only just above the level of spring-tides; consequently, the water in this reservoir is always below Trinity high water-mark. I pointed out that soakage from the adjacent foul river, and from the surrounding soil saturated with sewage, must take place into such an excavation, with its floor of 2½ acres in extent, an opinion which has been confirmed by a recent investigation of this reservoir when emptied, as far as possible, by pumping. The mortality from cholera in that portion of London supplied from these reservoirs was frightful; for, whilst the

deaths in the districts drawing water from other sources varied from 2 to 12 in 10,000, they ranged from 63 to 111 in 10,000 in those districts supplied from Old Ford.

**PRESENT METROPOLITAN WATER SUPPLY.**—London is, at present, supplied with water by nine companies, who deliver about 108,000,000 gallons daily. Some idea may be formed of the vastness of this supply by a comparison of its volume with some well-known magnitude. If it were contained in a reservoir having a floor area equal to that of Westminster Hall, the walls would require to be carried to the height of 1070 feet or more than three times the height of the Victoria Tower, to enable it to contain the water which is daily distributed in the metropolis. Five of the water companies abstract about one-half of the total supply from the Thames, two withdraw about 42,000,000 gallons from the river Lea, and the remainder is pumped by two other companies (the Kent and South Essex Companies) from Artesian wells sunk into the chalk of the Thames basin. Such is the present volume of water daily supplied to London and its suburbs; what will be the amount required twenty years hence it is difficult to estimate, but if the annual rate of increase since 1850 be continued, it can scarcely be less than 150,000,000 of gallons; for, in 1850, the gross daily quantity delivered was only 44½ millions of gallons, in 1856 it had reached 81,000,000 of gallons, whilst in 1865 it was 108,000,000 of gallons.

**PROPOSED WATER SUPPLY OF LONDON.**—Notwithstanding the best efforts of the water companies, the present supply of water to the metropolis is far from satisfactory, owing to causes which are mostly beyond the control of those to whom that supply is entrusted; it is therefore contemplated either to change entirely the source of supply, and thus obtain water of greater purity than any available in the neighbourhood of London, or so to alter the conditions at present affecting Thames water as to materially improve its quality. For this purpose no less than five schemes have been recently brought forward, viz:—

1. Sources of the Severn—proposed by Mr. Bateman.
2. The Cumberland Lakes—Messrs. Hemans and Hasard.
3. Thames Water, filtered through Bagshot Sands—Mr. Telford Macneill.
4. Storage Reservoirs near the Sources of the Thames—Mr. Bailey Denton.
5. Derbyshire and Staffordshire Hills—Mr. Remington.

The last three of these schemes have scarcely yet assumed a shape for discussion from a chemical point of view, we shall therefore confine our attention to the first two.

**MR. BATEMAN'S SCHEME.**—Mr. Bateman proposes to obtain the metropolitan water-supply from the mountain ranges of Cader Idris and Plynlimmon, in North Wales, which constitute the chief sources of the Severn. These mountains rear their heads into the moist air brought from the Atlantic by the prevailing south-westerly winds, and receive the precipitation of from 70 to 150 inches of rain per annum. We should thus avail ourselves of a great natural and very active distillatory apparatus, furnishing water of great purity. These Welsh hills consist of the Upper and Lower Silurian formations, "which yield water as pure in quality as that of Loch Katrine, and which afford sites for magnificent reservoirs, which may be constructed with perfect safety and facility, and of sufficient capacity to economize the full annual rainfall I have assumed, and to last out droughts of from 140 to 150 days' duration, both for town supply and river compensation. One of these districts of 66,000 acres in area, is situated a little to the east of the range of mountains of which Cader Idris and Aran Mowddy are the highest summits, forming the drainage-ground of the Rivers Banw and Vyrnwy; the other district of about equal area, is situated immediately to the east of Plynlimmon, 2500 feet in height. The discharge-pipes of the lowest reservoir in each of these districts will be placed at an elevation of about 450 feet above the level of Trinity high water-mark. The water will be conducted by separate aqueducts of 19 miles and 21½ miles in length respectively, to a point of junction near Martin Mere, from whence the joint volume of the water will be conveyed by

a common aqueduct to the high land near Stanmore, where extensive service-reservoirs must be constructed, which will be at an elevation of at least 250 feet above Trinity high water-mark. From these reservoirs the water will be delivered to the city at high-pressure, and under the constant supply-system. The total distance from the reservoirs on the Severn to London will be 183 miles. One of the reservoirs on the River Vyrnwy will, by an embankment of 76 feet in height, form a lake of five miles in length, and will contain 1,089,000,000 cubic feet. Another on the River Banw, by an embankment of 80 feet in height, will form a lake of four miles in length, and contain 940,000,000 cubic feet; and a third in the same district, by an embankment of similar height, will contain 732,000,000 cubic feet. Amongst the reservoirs on the Severn will be one which, by an embankment of 75 feet in height, will contain 2,230,000,000 cubic feet—this single reservoir being 50 per cent. greater than the available water in Loch Katrine." Mr. Bateman estimates the cost for 220,000,000 gallons per day at £10,850,000, the interest upon which, together with cost of maintenance, &c., would be met by a domestic rate of 10d. in the £, and a public rate of 2d. in the £. The present rate paid to the London water companies is much heavier, being about 1s. 5d. in the £. The total gathering ground in Mr. Bateman's scheme is estimated at 204 square miles.

**MESSRS. HEMANS AND HASSARD'S SCHEME.**—This scheme lays under contribution the magnificent condensing surface of the Cumberland and Westmoreland mountains, where, as every tourist knows, rainless days are rare exceptions. The extent of gathering-ground would be 177 square miles, whilst the average annual rainfall in the district is 100·56 inches. The districts from which water is proposed to be taken lie on the northern slopes of the range of hills towering over Grassmere, Windermere, and Kendal, and draining into the Rivers Lowther and Greta, and into the lakes of Haweswater, Ullswater, and Thirlmere. This scheme has the advantage of naturally-formed reservoirs, which would, however, require to be further enlarged by embankments; and these natural advantages are also to some extent counterbalanced by a greater length of conduit (280 miles), and by the necessity for several tunnels, two of which would be respectively  $7\frac{1}{2}$  and 8 miles long. The daily delivery of water in London would be 250,000,000 gallons, and the cost of works, &c., £13,500,000. The interest upon this capital, cost of maintenance, &c., and compensation to present water companies, would be met by a rate of 1s. 1d. per £1.

From a chemical point of view, it is at present quite impossible to give the preference to one or the other of these colossal schemes, both of which are truly worthy of the latter half of this century of engineering triumphs, and of the great city on behalf of which they are projected. Before we can appreciate, however, the advantages of such magnificent undertakings, it is necessary that we should first consider the chemical quality of our present supply, and compare it with that of the water which would be obtained from these new sources.

**ANALYSIS OF POTABLE WATERS—QUALITY OF THE PRESENT METROPOLITAN WATER SUPPLY.**—Absolutely pure water is never found in nature. In addition to mechanically-suspended impurities which can be mostly removed by filtration, potable waters also contain various solid substances in a state of solution. These substances are left behind as a solid residue when such waters are evaporated to dryness; they have been commonly classified by chemists under the three following divisions:—

1. Matters which are expelled when the solid residue is heated to redness in contact with air.
2. Matters which are not expelled at a red heat, and which decompose soap.
3. Matters which are not expelled at a red heat, and which do not decompose soap.

The substances of the first division consist of—

(a.) Organic matter.

(b.) The products of the decomposition of certain mineral salts, chiefly nitrites and nitrates.

Formerly ammoniacal salts, a certain amount of moisture, and even hydrochloric acid, were amongst the products expelled on ignition, but since the adoption of the suggestion of Hofmann and Blyth in the year 1856, to add a known weight of carbonate of soda to the water before evaporation, these substances have been excluded from category No. 1, and it is important to bear this in mind when comparing the analyses of water made prior to 1856 with those which have been made since that year. Notwithstanding the more definite character, however, thus given to the matters expelled on ignition, it is still difficult to interpret the meaning of this loss. It may all arise from organic matter, nay, there may even be more organic matter in the solid residue of a water than is indicated by the total loss on ignition, as I have recently had occasion to observe—or it may be all due to the dissipation of mineral ingredients, the result however of the decomposition of previously existing organic matter. When it is large it throws suspicion upon the character of the water, it indicates either the presence of organic matter, animal or vegetable, or it denotes previous contamination with sewage or decaying animal matters. This analytical determination is thus surrounded with much uncertainty, and it has always been considered, as indeed it deserved to be, highly unsatisfactory. Hence the attempts which have been made to indicate directly or indirectly, by means of permanganate of potash, the amount of real organic matter involved in this loss by ignition. Permanganate of potash when dissolved in water readily yields oxygen to many substances capable of combining with this element. Thus, if it be added to water, acidulated with sulphuric acid, and containing oxalic acid in solution, the latter is completely and rapidly converted into carbonic acid and water at the expense of oxygen derived from the permanganate, and it is found that one part by weight of oxalic acid, in being thus oxidised, abstracts almost exactly eight parts by weight of oxygen from the permanganate, the latter being converted into sulphate of manganese. In undergoing this chemical change the rich violet colour of the solution of permanganate of potash vanishes, and it is thus easy to ascertain by the non-disappearance of the characteristic tint of the permanganate, when the oxidation of the oxalic acid is complete. Now, a similar disappearance of colour occurs when the solution of permanganate of potash is added to an acidulated sample of potable water containing organic matter, and it has been assumed that, as in the case of the oxalic acid, the organic matter contained in the water is completely oxidised by the permanganate, which was thus thought to indicate the amount of oxygen required to oxidise completely the organic matter contained in the water. Dr. Letheby has even employed this reaction for the estimation of the *actual weight* of organic matter contained in a known volume of water, on the assumption that every grain of organic matter contained in a sample of water, robs the permanganate solution of eight grains of oxygen. Such a method of ascertaining the actual amount of organic matter in a water, or even the amount of oxygen required to convert this organic matter into its final mineral products of oxidation would be invaluable, on account of the extreme facility with which it can be applied, and it was, therefore, not without a certain amount of regret that, after employing this process for many months, I noticed unmistakable symptoms of its untrustworthiness, symptoms which were amply confirmed on submitting the process to rigorous experimental tests. By the addition of known weights of different organic substances to equal volumes of pure distilled water, the latter was artificially contaminated with a known proportion of each kind of organic matter. In fact, each sample of water thus artificially contaminated contained three parts of organic matter in 100,000. I then proceeded to ascertain first the amount of oxygen which this organic matter abstracted from the permanganate of potash, and secondly, the actual amount of organic matter present in the water, on the assumption that each part by weight of organic matter consumed eight parts by weight of oxygen from the permanganate of potash. The same test was also applied to another sample

of distilled water from which all organic matter was carefully excluded, but to each 100,000 parts of which three parts of nitrate of soda were added. The importance of this last experiment will be evident when it is stated that nitrite of soda is rarely absent from the different waters supplied to London. The amount of oxygen consumed by the organic matter was determined for two different periods of time, viz.—first, for a period at the end of which the acidulated and contaminated water remained tinted with permanganate for ten minutes after the addition of the latter, and secondly, for a period of six hours, during the whole of which time the permanganate was present in excess.

The results are contained in the following table where they are compared with the known amount of organic matter present, and the known amount of oxygen which that organic matter would require for its complete oxidation:

1 Name of substance, 3 parts of which were contained in 100,000 parts of water.	2 Oxygen absorbed in ten minutes. (Experiment.)	3 Oxygen absorbed in six hours. (Experiment.)	4 Oxygen required to oxidise organic matter. (Calculated.)	5 Amount of organic matter present. (Calculated from column No. 2.)	6 Amount of organic matter present. (Calculated from column No. 3.)	7 Amount of organic matter actually present.

Nitrate of Soda	·6910	·6913	0·00	5·528	5·530	0·0

From this table it is seen that of the nine kinds of organic matter operated upon, only one was completely oxidised by permanganate of potash, even after the lapse of six hours, whilst, it will be remarked, that urea, hippuric acid, and creatin—three organic substances likely to be present in water recently contaminated with sewage—suffer an oxidation which, even in the most favourable case, only reaches 1-100th of complete oxidation; whilst, if we attempt to calculate the amount of these substances present in the water, from the quantity of oxygen so absorbed, instead of finding 3 parts of each in 100,000 of water, we obtain only ·138 part of creatin, ·095 part of urea, and ·480 part of hippuric acid. On the other hand, the mineral salt, nitrite of soda, weight for weight, surpasses every form of organic matter experimented upon, in the avidity with which it absorbs oxygen; and 3 parts of this inorganic substance in 100,000 of water, would actually, by the mode of calculation above described, indicate no less than 5½ parts of organic matter. Thus, it is evident, that for the estimation of the amount of organic matter in water, or the quantity of oxygen necessary to oxidise that organic matter, permanganate of potash is utterly untrustworthy and fallacious. Whilst, however, this reagent is quite worthless for the quantitative estimation of organic matter in water, it may still be used in certain cases as a qualitative test, where there is no opportunity for accurate analytical examination. Thus, if a clear and colourless water decolorises much of the permanganate solution, the water ought to be rejected for domestic use, as being of *doubtful* quality, for although such a water may be absolutely free from organic impurity, yet its decolorizing action upon the permanganate would indicate, with considerable certainty, that the water had been in contact with decaying animal matters. Should the water, however, instead of being colourless, be tinged of a yellow or brownish yellow colour, when looked at through a considerable stratum, as in a decanter, for instance, its capability of decolorizing a considerable amount of permanganate solution, ought not to be regarded with the same suspicion as in the case of a colourless water, because the yellow tint of such waters is generally owing to the presence of peaty matter which, though innocuous, has the power of decolorizing permanganate of potash.

Having thus convinced myself of the fallacy of the permanganate process of analysis, and there being no other method by which the estimation of organic matter in waters can be even approximately effected, I have, for some months past, in conjunction with my pupil Mr. Armstrong, been endeavouring to remedy this grave defect in water analysis, and we have at length succeeded in replacing the unsatisfactory item of "organic and other volatile matter" by certain precise and definite determinations, which throw great light upon the present condition and previous history of the sample of water submitted to analysis.

The most important things to be ascertained about a water used for domestic purposes are, first the amount and character of the organic matter present in the water at the time of analysis; and, secondly, the amount of hardening or soap-destroying materials which the water contains. Unfortunately, the first of these data cannot be ascertained, but we have devised processes by which the amount of the two most important elements of organic matter, carbon and nitrogen, can be determined with considerable precision. For this purpose, the following processes are necessary:—

1. Determination of the carbon contained in the organic matter. To distinguish this carbon from that which is contained in the mineral carbonates present in most waters, I will term it *organic carbon*.
2. Determination of the total combined nitrogen. This nitrogen may exist in the water in one or more of the three following forms:—(a.) As a constituent of organic matter—*organic nitrogen*; (b.) as a constituent of mineral nitrites and nitrates; (c.) as a constituent of ammonia.
3. Determination of the nitrogen present as nitrites or nitrates.
4. Determination of ammonia.
5. Calculation of amount of organic nitrogen. This is obviously a very simple operation, for if, from the amount of total combined nitrogen (determination No. 2), there be deducted the amount of nitrogen present, as nitrites and nitrates (determination No. 3), plus the amount of nitrogen present in the ammonia (determination No. 4), the remainder will be the amount of organic nitrogen.

The processes by which these determinations are made, will be fully described elsewhere.

(To be continued.)

## CLINICAL LECTURES

DELIVERED IN

STEEVENS' HOSPITAL,

TOGETHER WITH

OBSERVATIONS ON PRACTICAL MEDICINE.

By Sir HENRY MARSH, M.D., Bart.,

PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

Edited by J. STANNUS HUGHES, M.D., F.R.C.S.I.,

PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS IN IRELAND,  
SURGEON TO THE LORD LIEUTENANT'S HOUSEHOLD.

REFLECTIONS ON THE CAUSES OF DROPSY.\*

BEFORE I proceed further in the consideration of the hemorrhages it will be expedient to dwell as succinctly as possible upon that variety of extravasation which I have formerly termed the white blood hemorrhage, or, in other words, dropsy or hydrops, so called from the resemblance which the uncoloured extravasation derived from the serum of the blood bears to water. In this there is more an appearance than a reality of divergence from my original subject.

In the year 1846 I published in this Journal some remarks upon chlorosis and hemorrhage, with the view of contrasting the one with the other, and also of contrasting the red blood and the white blood hemorrhages. The word

\* Reprinted from the Dublin Quarterly Journal of Medical Science, Vol. xvi. August 1, 1853.

hemorrhage is applicable to both because both are derived from the blood.\* I also remarked upon some of the pathological differences between chlorotic and hemorrhagic blood, the first low in density and in the proportion of red corpuscles; the second, ere yet reiterated hemorrhages have thinned and debased the blood, abnormally exalted in density, superabundant in red corpuscles, and deficient in fibrine.

It is now my purpose, that the subject of the hemorrhages may be rendered more clear, to make a few general remarks upon the causes of the white blood hemorrhages, or dropsies. To expose my views on this subject I shall speak of dropsy under three distinct heads: atonic dropsy, obstructive dropsy, inflammatory dropsy. There are few of the dropsies which we daily meet with in practice that will not find a befitting place under one or more of these heads.

By atonic dropsy I mean all those dropsical effusions which are the results of pre-existing morbid or febrile action,—of wasting and softening of the solids, of degeneration of the blood, and consequent atonicity of the vascular tissue.

By obstructive dropsy I would imply all those dropsies which result from organic disease of the heart, lungs, liver, spleen, &c.; and from tumours and other morbid growths which mechanically obstruct the circulation,—such obstruction causing the blood to stagnate in and to distend the venous trunks and capillary system, so that they become surcharged, and are compelled, if I may so say, to seek relief by a serous extravasation. When I reach this part of my subject I shall have occasion to show that obstruction is frequently not the sole cause of the white blood extravasation,—that more than one cause is influential.

By inflammatory dropsy I mean all those dropsies, and they are many in number and variety, which owe their origin to serous inflammation. This most important branch of my subject will require hereafter to be fully explored.†

The red blood hemorrhages, as I have elsewhere noted, are naturally and practically divisible into the passive and the active. No two varieties of the same disease can be more diverse in causality and treatment—where the cases are well marked—than are the active and the passive red blood hemorrhages. The same observation is strictly applicable to the white blood hemorrhages or dropsies. The atonic hydropic effusions represent the passive red hemorrhages? the inflammatory, the active:—the parallel is perfect. Between the passive and active dropsies there are some remarkable discrepancies which may just be glanced at. In the passive or atonic the effusion takes place usually towards the close of prolonged chronic diseases,—it is one of the latest and most fatal indications: whereas in the active or inflammatory, serous extravasation is often synchronous with the first signs of morbid action. This is particularly remarkable in the anasarca of albuminuria.‡

In the passive or atonic the extravasation is generally first perceived in the most depending parts, commencing slightly and gradually, ascending from below upwards, invading the infracutaneous serous tissue, and ultimately the serous tissue of the cavities. But such is not ordinarily the course of active dropsy.

There is another very remarkable difference between these distinct varieties, viz., that which relates to the density of the extravasated fluid. In the passive or atonic dropsy it is, with not many exceptions, exceedingly thin and fluid; it consists, in fact, of the thinnest serosity,—only the most watery parts of the blood are exhaled. A proof of this is derivable from the slight degree of pressure needed to produce a pitting or indentation, and the rapidity with which the pitting or dimple is obliterated, and the

fluid replaced; and in extreme cases, the transparency of the skin shows the fluidity and clearness of the subjacent extravasation; whereas generally in acute anasarca the effused fluid is more opaque, dense, firm, and resisting; a heavier pressure is required to produce a dimple; the dimple or pit is more slowly effaced. In some cases the fluid productive of anasarca is so thick and glutinous, that it requires much force to displace it, and, being displaced, very slowly is the smoothness of the skin restored. So great is the density sometimes, that even in those parts of the body where the cuticle and cutis are thinnest and softest, scarcely any amount of pressure can cause an impression; and thus we have presented to us that which I shall have occasion to dwell upon hereafter, viz., the anasarca dura,—a very interesting variety of anasarca. It belongs to the inflammatory section of dropsical effusions, and shall there be treated of. There results from the density and tenacity of the effused fluid another and conclusive test, viz., acupuncture. In the passive dropsy the tenacity of the fluid enables it to escape through the punctures freely and copiously, and in a stream. In the active, it escapes slowly and unwillingly, or, in some cases, not at all; consequently these are cases in which acupuncture is absolutely fruitless.

Such are, in a general way, some of the signs which in well-marked cases distinguish the active and passive varieties of dropsy.

Between the extremes of the thinnest serosity and the densest white blood exudations, the gradations are numberless, and often imperceptible; they pass insensibly from the one into the other. In all animated nature, when extremes approach, the lines of demarcation are oftentimes inappreciable. This, in disease, is as true as in the various kingdoms of organized nature; and therefore it is necessary, in the study of disease, to arrive at just conclusions by the contemplation of clear, distinct, and well-defined cases.

There is another distinction between active and passive dropsies which just occurs to my mind. In passive dropsies, the effused fluid is, with few exceptions, unmingled with the red corpuscles of the blood; they are rarely suffered to escape. In active or inflammatory exudations, the admixture of red corpuscles is of far more frequent occurrence. Why this should be the case, and what the true nature of serous inflammation is, I will endeavour to expose when the inflammatory dropsies shall be treated of.\*

The great interest which attaches itself to the careful study of white blood abnormal extravasations is derived, not only from therapeutic considerations, but also from the vast variety of pathological changes both in the fluids and solids which give origin to this frequently ominous symptom.

In reviewing the causes of passive or atonic dropsy, the clearest perceptions will be obtained by a brief statement of the facts of a few expressive cases. This symptom sometimes springs from a morbid change in the blood alone; sometimes from the more formidable source of organic visceral disease giving rise to a morbid change in the blood. When chronic visceral disorganizations terminate in dropsy, I have known as much terror excited in the patient's mind by the first appearance of œdema in the insteps and ankles, as there is by a sudden attack of profuse hæmoptysis.

œdema of the feet and ankles is often first distinctly perceived at bed-time. In the recumbent position the thin fluid diffuses itself through the areolar tissue. In the morning it has apparently vanished, but towards night the dreaded symptom re-establishes itself. When the patient resumes the sitting position, the fluid gravitates downwards, and the patient finds his legs again swollen, and thus his fond and vain hopes are dissipated. Great indeed is the popular dread not only of the appearance, but of the

\* Between the red blood and the white blood hemorrhage there is this difference, that the former is an extravasation of the blood in its entirety, whereas the latter is one of only certain portions of the blood, either not mingled at all, or but in a small degree mingled with red corpuscles.

† Many of those dropsies to which the epithet encysted is by some writers applied, will find a place under this head.

‡ I use the word "albuminuria" because, whilst it points to a specific disease, it implies not a theory, but a fact.

\* The true cause of the infra-cutaneous extravasation which takes place at the commencement of renal anasarca is, I am persuaded, to be traced to serous or albuminous inflammation affecting the infra-cutaneous serous tissue; an inflammation precisely of the same nature as, and in all respects analogous to, that which affects the kidneys.

very name, of dropsy, and there is no disease more dreaded than that popularly called water on the chest.

The following fact, which I noted twenty-seven or twenty-eight years ago, impressed itself strongly at the time upon my mind, and I have often since in my lectures recurred to it as an exemplification of the passive or atonic dropsy without organic lesion.

A gentleman, thirty-five years of age, having been not more than three weeks recovered from maculated fever, performed in a remarkably easy carriage, and in summer, a journey of about fifty miles. The fever was one of the most formidable character, the undoubted offspring of contagion, so dangerous that at one time his medical attendants abandoned all hope of his recovery. At an early stage of the disease he was bled from the arm to ten ounces; subsequently so urgent were the cerebral symptoms that he was largely and repeatedly leeches. His skin was universally and darkly maculated; the fever was a protracted one; scarcely before the twenty-first day could it be said that it had quite subsided; the period of convalescence was painfully protracted by extensive sloughing of the nates. When the sores were healed, and strength somewhat reinstated, he travelled fifty miles from the city, and on reaching the end of his journey, he complained of stiffness in the joints of the lower limbs. The drawers and stockings were with difficulty removed. He was very much shocked and alarmed to find his limbs, as high as the hips, immensely swollen, and pitting everywhere on the slightest pressure; the scrotum and penis were also much distended.

The functions were all healthily performed; urine perfectly natural; bowels regular; no sign whatsoever of organic lesion, only he was pallid in the extreme, and greatly reduced in flesh and strength. Mild medicine, tonic and diuretic, pure bracing air, improving appetite and diet, wrought in this gentleman a miraculous and speedy change for the better. After the lapse of a few days the dropsy was so far subdued that he was enabled to take quiet walking exercise in the open air, which seemed to have the effect of promoting absorption. The improvement of the general health, and the subsidence of the dropsy, moved together "*pari passu*," no long time elapsed ere restoration was perfected. He is now in robust and vigorous health; never before nor since has he shown the slightest tendency to any form or variety of hydropic effusion. During the fever I remained constantly with him, and accompanied him in his journey. I was then a tyro, but at the time and often since I have thought that had he been less profusely bled, he might have been spared the extreme debility and the sloughing.

This example appears to me a good illustration of dropsy as a result of the wasting and softening of the tissues without organic lesion of any of the solid viscera.

There were in this case a prolonged and dangerous fever, and a tedious convalescence.

(To be continued.)

## CLINICAL LECTURE ON STONE.

By JOHN ADAMS,

SENIOR SURGEON TO THE LONDON HOSPITAL.

THERE is often difficulty in deciding whether a patient had better be cut for stone, or whether it is not preferable to break up the stone in the bladder, as in the operation of lithotrity. No doubt the latter operation is preferable when circumstances are favourable, but the same may be said of any operation. The subject is, however, now so well understood that it is unnecessary to say much about it, although, even now, some surgeons are in favour of the old operation of cutting in all cases, and decline to adopt the opinion expressed by Sir Benjamin Brodie, that lithotrity is the operation for stone and lithotomy the exception.

I show you some debris of stone which a patient voided after repeated crushings, and by which he was eventually completely cured. The patient was a gentleman, 72 years old, and suffered under the ordinary symptoms of stone. The case was one of unusual facility for operation. The bladder,

although irritable, was able, under a slight administration of chloroform, to hold a few ounces of water; the urethra was large, and the stone was soft and visible, so that a large quantity of phosphatic matter was readily withdrawn by the scoop lithotrite repeatedly introduced at each sitting. He was scarcely confined to his house during the various operations, and was able to go about his usual business, which required a great deal of walking. The fragments are of great size, and he had very little difficulty in getting rid of them *per vias naturales*.

It is, however, in cases where the stone is large and hard, that lithotrity is inadmissible, and lithotomy must be resorted to. But it is not my intention to go into the whole history of cases of stone, and to consider a subject on which so many surgeons delight to dwell. I want to direct your attention to cases which are of very frequent occurrence, cases unfortunately within the experience of most surgeons, in which it is better not to operate at all, rather than incur the risk of destroying the patient at once by the performance of the operation of lithotomy. Certainly there are many cases in which the suffering of the patient is so great that death is less to be dreaded than a continuance of life, and the surgeon is inclined, or is even solicited, to operate, by way of attempting something which may, perchance, relieve his patient. Such operations are almost invariably futile and terminate unsuccessfully, and should, in my opinion, be avoided. But I admit the difficulty in coming to such a conclusion, and I am always too glad to adopt any suggestion at variance with this opinion, provided the patient's sufferings justify me in this respect; but I have long since ceased to advise an operation where the prospects of success are at *nil*.

In the museum of the College of Surgeons there is a stone which weighed over forty ounces. The operation of lithotomy was commenced by Mr. Clive senior, but the attempts at its removal were futile, and the patient, Sir Walter Ogilvie, died almost on the operating table. No attempt ought to have been made to remove this stone, which, in consequence of its size, could not have passed through the pelvis. However, as the argument is *ex post facto* it is scarcely worth all the consideration to which it would otherwise have been entitled. At any rate the removal of such enormous calculi should never be attempted.

Two cases of stone in the bladder occurred to myself some years ago where, from the size of the stone in each, and from the obvious disease of the entire urinary apparatus, no attempt at removal was deemed advisable, and the patients gradually sank with no extraordinary amount of suffering.

Mr. Coulson, in his valuable book on "Lithotrity and Lithotomy," has collected from various sources, cases of very large stone successfully removed by operation; but it may be generally stated that stones exceeding twelve ounces in weight can very rarely be successfully extracted after cutting.

A friend of my own, advanced in years, was cut by the late Mr. Key, assisted by Sir Benjamin Brodie, but the stone was so large that it could not be extracted, and the patient died immediately after his removal to bed. Such cases must have occurred to most surgeons of experience, and it has frequently happened that the patient has run the gauntlet of all the bystanders in the operating theatre, and yet no force could remove the stone owing to its great size, notwithstanding large incisions were made on both sides of the prostate gland.

But to what do my observations tend? Simply to this, that in very many cases of stone no operation by cutting should be attempted; and that, if lithotrity fails to effect a cure, such cases should be let alone, and life, which may often be prolonged, should be made easy by suitable medicinal and diatetic measures. My remarks are especially applicable to persons of advanced age; for in these, as the stone increases in size, it ceases to roll against the neck of the bladder, and thus the greatest cause of irritation is gone; besides, the prostate is often large in such cases, and this also keeps the stone from coming in contact with the sensitive *cervix vesicæ*.

A gentleman, whose case is familiar to me, has been the subject of stone in the bladder for many years; his age is between 70 and 80, and his life seems likely to be prolonged even much further; he remains in the recumbent posture either in bed or on the sofa, and all irritation is either prevented by this position, or is subdued by opium.

Three years ago a gentleman, 80 years of age, consulted me about a constant passing of bloody urine, accompanied by an irritable state of the bladder. I sounded him and found a stone. I advised that an attempt should be made to crush it by lithotripsy. He declined to have any operation performed. I ordered him some henbane and liq. potasse, and on calling on him in the country the summer before last, I found that he had gone out from home, and was told that he was in a comparatively comfortable state, and had little or no suffering. I have recently heard from his surgeon that he suffers little or nothing from the stone, except an occasional attack of hæmorrhage.

A patient nearly 80 years of age was brought to me last year with symptoms of stone. I sounded him and found a large stone. I introduced the lithotrite, but could not grasp the stone owing to its size. He declined any further attempts at operation. He is now in comparative health, but he is obliged generally every night to draw his water off, and by this means he keeps himself in comparative comfort.

A gentleman was brought to me from the country by his surgeon with stone in the bladder. His age was 72, and he was a comparatively healthy man, and suffered little, and when quiet at home in the recumbent or sitting posture, felt no inconvenience. I could not seize the stone with the lithotrite in consequence of its size. I advised that no operation should be performed, but that he should keep himself quiet. I ordered him henbane and potash. I have reason to believe that he is now in comparative ease, having undergone no operation whatever.

I should be exceedingly sorry to attempt to dogmatise on such slender experience as I have had in cases of this description, but I am anxious that surgeons should, in such cases as I have referred to, pause e'er they advise an operation, which, under such unfavourable circumstances, would be almost necessarily fatal, and to try whether life may not be rather prolonged by palliative treatment. Of course, my observations may be met by counter-statements of other men of larger experience who have operated on persons of advanced age, and have successfully removed very large calculi from the bladder: it is rather the indiscriminate use of the operation that I take the liberty to object to, being satisfied that death must almost of necessity be the result of operative interference. But I admit that it is almost impossible to lay down any rules to regulate our practice in many unfortunate cases. Much must be left to the prudence and discrimination of the surgeon.

It is not only that the size of the stone in old persons forms a fatal objection to lithotomy, but there are many other serious complications which should deter us from the performance of an operation which is attended with material danger, however dexterously performed. Thus, the discharge of pus with the urine, accompanied by emaciation and hectic albuminuria to any extent, the mixture of blood and pus, and intense pain in the bladder, indicative of ulceration of this viscus, may be mentioned as almost invariably prohibitory of lithotomy.

No doubt, in many cases, as the stone increases in size the symptoms diminish, a fact which admits of easy explanation; and if the ordinary symptoms are mitigated, it follows almost as a necessary corollary that those effects—more remote, but, perhaps, of more importance—are also diminished. Thus, inflammation of the bladder subsides, the ureters resume their original healthy condition, and the kidneys, if not already damaged, continue to discharge their wonted and important functions. I admit that such a consummation is scarcely to be expected; but the occasional persistence of comparative health under such a serious complication, as a large stone in the bladder, justifies a hope that life may be prolonged without any very great suffering.

A case was related to me last week which proves two things bearing on the subject now under our consideration. A gentleman, 70 years old, had had stone in the bladder many years, the size of which was such, that no operation was deemed advisable in his case. The symptoms gradually diminished, and he suffered little or nothing. One day he fell back suddenly, and he felt something give way in his bladder; inflammation of this viscus commenced; urgent symptoms occurred, and he soon sank under their effects. There can be no doubt that in this case the stone, which had been originally fixed, was dislodged by the concussion, and thus became a source of fatal inflammation to the bladder and kidneys.

The treatment to be followed in such cases may be very briefly described, and consists of—1st, rest, as much as possible in the recumbent position; 2ndly, the hip-bath; 3rdly, the administration of alkalies and henbane; 4thly, opiates in moderation; 5thly, the employment of the catheter occasionally, and if the pain in the discharge of the urine is excessive and followed by painful spasm of the bladder, an elastic catheter may be retained in the bladder to allow the urine to dribble away; attention to the bowels, and simple, but not abstemious, diet should also be enjoined.

Irrespective of the surgical aspects of cases of stone in advanced age, and under serious pathological conditions, a case may assume very great importance in other respects. I may illustrate my position by reference to a case well known to many surgeons of this metropolis. A gentleman between 70 and 80 years of age, had stone in the bladder. His sufferings were not acute, and no operation was advised, or, if advised, was not assented to. His life was heavily insured, and, by the articles of insurance, he was entitled to a large quinquennial bonus if he lived beyond a certain day. He outlived the specified time, and his family thereby received a very large addition to the original policy at his death. What would have been the case had he submitted to the operation of lithotomy? Certainly, he might have recovered, but the chances would have been, in my opinion, much against him.

*Hospitals for Calculous Diseases.*—I cannot help thinking that those philanthropic men who appear to be so earnest in advocating the necessity for special hospitals, would do some real good to society if they would erect an institution for the admission and treatment of such cases as are beyond the powers of the ordinary surgeon—I allude to such cases of stone in the bladder as do not admit of relief by the operation of cutting or lithotripsy—we might thus have the means of judging how long life might be prolonged, and pain mitigated, by careful treatment. We should then possibly be spared the immense mortality in stone operations—a mortality obviously materially enhanced by the too frequent performance of lithotomy when cases are positively hopeless.

Whilst these remarks have been passing through the press, I have seen the observations on stone, by Mr. Cadge, of the Norfolk and Norwich Hospital. The cases have most forcibly struck me as essentially corroborative of my opinion, and deserve the most careful reading, as proving, rather more than I have attempted to prove, that even lithotripsy cannot always be advocated in advanced age, when there is reason to believe that the bladder and kidneys are much diseased.

---

EXTRACTED FROM THE "LONDON GAZETTE."—WHITEHALL, APRIL 18, 1867.—The Queen has been pleased to grant unto John Simpson, of Castle Lodge, in the parish of Knaresborough, of Dore House, in the parish of Handsworth, both in the west riding of the county of York, and of Gloucester-place, Portman-square, in the county of Middlesex, Esquire, doctor in medicine, and in the commission of the peace for the said west riding, her Royal licence and authority, that he and his issue by Elizabeth Simpson, his wife (who is the sole heir and representative of her maternal uncle, Andrew Hudleston, late of Whitehaven, in the county of Cumberland, doctor in divinity, incumbent of Whitehaven, and rector of Bowness, in the said county of Cumberland, deceased), may take and henceforth use the surname of Hudleston in lieu and instead of that of Simpson, and bear the arms of Hudleston.

## Original Communication.

### ON PEMPHIGUS.

By JOHN HUGHES, M.D.,

PHYSICIAN TO THE MATER MISERICORDIÆ HOSPITAL.

(Read at a Meeting of the Medical Society of the College of Physicians.)

Patrick Morrin, aged 11, a healthy-looking boy, with brown hair and eyes, a good complexion, and apparently well nourished, was admitted into Mater Misericordiæ Hospital Feb. 7th, 1867. He is a very intelligent lad, and states that both his parents are alive and healthy, and that he has never suffered any privations. He lived in Smithfield in a well ventilated house, and had an abundant supply of food and good clothing. He states that although he could have animal food twice or three times a-week, yet he preferred and mainly used, farinaceous diet. He always enjoyed good health until the commencement of his present attack, which occurred on the 3rd inst. On that day (Sunday) he went to the Park, where he engaged in a game of foot-ball, became very warm and perspired a great deal; he then sat on the grass to cool himself, but did not feel chilled.

In the evening, after he returned home, and during the night he was very thirsty, and drank water several times out of a vessel where it had remained some days, and which tasted badly; he was obliged to do so, because the usual supply was cut off from the house on account of the bursting of the pipes in the preceding frosty weather.

4th inst.: Next morning he went to his usual work—viz. (cleaning a cattle yard); still felt thirsty, and drank copiously of the same water.

5th inst.: On this day he was pretty much in the same state; hardly well enough to do anything, yet not ill enough to remain in bed, but still thirsty and drinking the same quality of water until evening, when he had a *shivering fit* for the first time, and felt worse than before; he was restless and slept badly during that night, and when he awoke the following morning he noticed two pimples, as he calls them, on the outside of the right thigh; the larger one being about the size of a sixpence, and one on the outer side of left thigh something smaller. They all burst in a short time by the rubbing of his clothes, and felt very sore. Others were making their appearance on various parts of his body; and as he was very sick, and feared he might communicate the disease to his brother, with whom he slept, he applied for admission to the hospital the day after the eruption manifested itself. Having been received after the usual visiting hour, he was not examined until the next day, Friday, the fifth day of his illness, and the third of the appearance of the eruption, which was then beautifully marked.

The original bullæ were destroyed by friction, and an excoriating surface marked their site: one was an inch in diameter, and others were developed on the thighs, down to the knees; thinly scattered; but over the neck, anteriorly and posteriorly, a crop was appearing, which promised to surround it like a collar, as it eventually did by the coalescence of the bullæ.

Next day (sixth day), still more bullæ were appearing on the front of the chest, on the back, and a few scattered ones on the arms. On Sunday (seventh day) the eruption seemed to be fully developed, and it might be observed in every stage of its progress, and on every region of the body. No part escaped except the hands (both surfaces) and the soles of the feet, the scrotum, and penis. The bullæ were not equally numerous everywhere; but where they were thinly spread they attained the largest size. For instance, we measured one two inches in diameter on the outside of the thigh, and one equally large near the umbilicus; on the arms, also, they were very large, and they were, all of them, single bullæ; while on the back, and

around the neck, they were smaller in dimension, and quickly coalesced, owing to their close proximity to one another, and their more rapid development—in fact, those regions were completely covered, and when the cuticle was rubbed off, presented a uniform red and inflamed surface; just as if a blister had been applied to it. On the hairy scalp several bullæ were developed; they were quite distinct, and not large. On the tongue, also (around its margin), and on the mucous membrane of the palate they could be readily seen, and gave our poor patient great annoyance in his efforts to eat some bread, or to swallow fluids.

We could not observe any symmetry (as regards the two halves of the body) in the development of the eruption, although it is somewhat manifested in respect to the extremities, those on both sides being pretty equally affected. The skin between the bullæ was quite natural, no matter how closely they were placed.

Our patient was frequently interrogated as to whether he felt heat, pain, or itching before or during the appearance of eruption, and he always replied in the negative. He did not appear to be cognizant of any new crop of bullæ until after their rupture, and consequent exposure of the epidermis.

The eruption continued to appear by successive crops (the latest around the ankles and on the fore-arms) until Friday, the eighth day after his admission, the tenth or eleventh after the first bullæ were noticed by the patient; and during those days a certain amount of constitutional disturbance was present, characterised principally, if not altogether, by derangement of the digestive mucous membrane, which alone appeared to sympathise with the cutaneous affection.

For instance, there was anorexia and constant thirst, a foul tongue and confined bowels; but there was no nausea nor vomiting, no increased heat of surface, no accelerated breathing, no headache. The urine was normal; the pulse was regular, and did not exceed seventy-four beats in the minute, except on one day, when it reckoned eighty, probably from some passing excitement; and he complained of nothing except the irritation from the unavoidable friction against the denuded surface of the skin.

After Friday, no more bullæ appeared, his thirst declined, the tongue became clean, and the appetite returned.

At the end of a week he was out of bed, convalescent; some crusts and stains marking the places occupied by the eruption.

The progress of the eruption was watched from day to day, and we found from the outset that the large bullæ were perfectly useless for the purposes of observation; they were no sooner developed than they were ruptured by the friction of the bed-clothes and the movements of the patient.

Their course appeared to have been very rapid, and we saw nothing of them except the excoriated surface on which they stood.

Not so, however, as to the smaller ones; their progress appeared to be slower, and we could protect, to some extent, those which were situated on the front chest and upper extremities. Their course appeared to be as follows:—

First, a minute speck was observed without elevation of the cuticle; in twenty-four hours it was covered by a vesicle, about the size of a small pea, containing a transparent fluid, globular in shape, and without the slightest trace of an areola, even when viewed through a magnifying glass of considerable power. Next day the vesicle increased in size, but remained in every other respect unaltered.

On the third day, having attained its full size, the summit appeared slightly flattened, and the contained fluid began to lose its perfect transparency, while, at the same time, an areola, not wider than a hair's breath, could be seen around its base.

On the fourth day the fluid became decidedly opaque, more particularly marked at the summit of the vesicle, which was still flatter, and the areola grew wider and more distinct.

During the fifth and sixth days the contents of the

vesicle became sero-purulent, the areola spread, and the vesicle having burst, a thin crust was formed over the inflamed surface, which did not separate for some days after. Some of the contents were obtained from the transparent vesicles in their early stage, and it appeared to consist of an albuminous fluid easily coagulable by heat, and of a neutral quality. The duration of the disease was under three weeks, ten days of which were occupied in developing successive crops of bullæ without the slightest attempt at the healing of any, and the remaining days might be reckoned as the convalescent period.

During the progress of this case, the observations upon it were made and recorded at the bedside in presence of our hospital class, and I purposely abstained from referring to the literature of the subject until it had terminated. I am now disappointed in not being able to place it under either of the two forms into which pemphigus is divided by authors of works on "Dermatology"—namely, the acute and the chronic—for I find that it presented a combination of some of the signs and symptoms which are said to distinguish both.

For instance, the eruption was rapid in its development and short in duration; so far it might be considered acute, while, on the other hand, there was scarcely any fever or acceleration of the pulse, and thus it might be looked upon as non-acute or chronic. In the next place, the eruption itself presented all the characters which are said to distinguish and separate the two forms of the disease; some of the vesicles were small, and some were very large; some discharged their contents in forty-eight hours, while others remained transparent on the third day, and did not rupture till the fifth or sixth day; some were distinct from the beginning to the end, while others became confluent immediately they appeared. With respect to the inflammatory areola, which is said, and, one would expect, ought to be a striking and characteristic sign of the eruption, it was not discernible so long as the vesicle retained its transparency, but was established when the fluid became opaque, a change which we attributed to the irritating effect of the altered fluid upon the epidermis; and consequently of no value as separating the two forms of the disease.

Again, the eruption was very diffused, which we are told is a mark of the chronic disease; but it also occurred on the hairy scalp, where it should never be seen in that form. Altogether, after carefully reviewing the signs and symptoms of this case, which was undoubtedly well marked, and uncomplicated, we are inclined to the opinion that the appearances of the eruption and its locality are not sufficient guides to establish the two forms of pemphigus, as laid down in some works on dermatology. That the accompanying fever, heat, and itching bear little or no relation to the extent of the eruption, or the rapidity of its development; and that, if we except the duration of the attack, there are no data upon which to base this division. In fact, there seems to be no real distinction between the two forms, and the acuteness or chronicity of the disease depend more upon the duration of the attack, and the age and constitution of the patient, than on the character of the fever, or the appearances of the eruption. As regards the exciting cause of the disease, except the sudden arrest of the cutaneous secretion after violent exercise, I find no more efficient one in this case than the use of bad water. In the treatment of this case we saw no indications for depletion or lowering remedies; on the contrary our patient had a bark mixture, beef tea, milk with lime water, and even wine, all of which seemed to agree well with him, and to be required; and, with respect to local management, the carron oil liniment, and a weak solution of nitrite of silver, applied night and morning to the denuded epidermis, produced the best effects.

In standard works we are told it is injudicious to puncture the bullæ, because "we can apply to the excoriated surface no dressing so mild as its own albuminous secretion, and can protect the excoriated skin from the irritation of exposure by no covering so effectually as by its own cuticle." As regards the larger bullæ this caution is quite useless, because no efforts of ours can possibly prevent their

rupture, and in the case of the smaller ones their *early puncture and discharge of the transparent fluid we found to be the very best method of preserving the cuticle for the protection of the true skin.* We punctured daily a number of bullæ on the chest and arms containing a transparent secretion, and after they collapsed we found they were the *only ones* which healed kindly and without any suppuration whatever. But after the contained fluid became opaque, and an areola was formed, the opening of the bullæ did not appear to check the progress or alter the course of the disease.

Since the foregoing case was noted I have had under my care in hospital a second case of pemphigus, occurring in a girl, aged 17. The eruption first appeared in the form of a few large bullæ on the inside of the knee-joint on the 12th March; neither accompanied nor preceded by any marked constitutional disturbance; the pulse reckoned 80; the skin was cool; the tongue a little white, but moist, and locally there was only some sense of heat and smarting, with redness of the surface.

In fact, the patient thought so little about the affection, that she did not mention anything about it until she was observed to walk lamely, and when examined the first crop of bullæ were destroyed.

Successive crops appeared for four days, when the eruption ceased; the surface was quite healed on the 12th day, and she was out of bed. The skin, on the 28th March, retained the marks of each bulla, some small, others large, some distinct, and some confluent, but all confined to the surface of the knee-joint.

At the end of three weeks from its first appearance the eruption again presented itself, and was ushered in by a sense of heat and smarting in the same joint, a slight chill, but no acceleration of the pulse, or other marks of febrile disturbance, except a loss of appetite. Large bullæ first appeared on the outside of the knee-joint, then down the leg as far as the ankle. Next, in an upward direction, along the thigh, over the whole front of abdomen and lower half of sternal region, across to the right hypogastrium, and on the dorsal regions on either side of the spine.

The eruption travelled by successive crops over the course and in the order described, and took four weeks to complete the journey. It was composed of bullæ as large as a four-penny piece, and vesicles not larger than a pin's head.

A bright redness of the surface preceded and accompanied the appearance of some, while others had not the slightest trace of redness around them. But during all this time the pulse never exceeded 80, and the appetite was pretty good for one obliged to remain in bed.

The treatment of this case, both locally and constitutionally, was the same as the first recorded.

Tonics and full diet, with wine, were administered internally, while externally a Sol. of Nit. Argenti was freely applied to the exposed epidermis, and every bullæ discovered during its transparent state was punctured; and it was remarkable that the epidermis covered by bullæ thus treated was completely protected, and no excoriation or inflammatory action whatever succeeded their collapse.

I may here again remark that this case, like the preceding one, would tend to show how impossible it is to place Pemphigus amongst acute diseases, and how equally difficult it is to divide it into the two forms laid down in works on Dermatology. Certainly neither the character of the constitutional symptoms, nor the appearances and course of the eruption are sufficient, and if we must admit an acute and a chronic form of the disease, I am still of opinion that the duration of the attack is almost our only guide on which to base the distinction.

After reading his communication, Dr. Hughes showed the members of the Society a drawing of Morrin's case, made at early stage of the affection, and also the patient himself quite convalescent, but still exhibiting the marks of the eruption.

### CLINICAL REPORTS BY DR. HAYDEN.

#### RHEUMATISM.

SUB-ACUTE RHEUMATISM; ENDOCARDITIS, WITH MITRAL REGURGITATION; DIPHThERIC INFLAMMATION OF THE THROAT, AND HEMOPTYSIS.

M. J. R., aged 19, stationer's apprentice, admitted May 5th, 1867; healthy up to a fortnight since, when she was attacked with pain and swelling in both ankle-joints, and subsequently in both wrists. On admittance her pulse was 120, and full; tongue furred; perspiration moderate. No pain or tenderness in region of heart; cardiac impulse and precordial dulness normal. A soft bellows-murmur replacing the first sound of the heart was audible over the apex, and in the left axilla, but not at the base, where both sounds were normal, nor in the left back.

To have gr.  $\frac{1}{2}$  of calomel, with gr. i. of James's powder, every hour; and beef-tea with bread-crumbs.

May 6.—Soft palate and uvula are covered with a diffuse dark-red blush, interspersed with patches of a yellow deposit, like that of diphtheria. Throat to be touched with a linctus composed of chlorate of potass., hydrochloric acid, and treacle.

7th.—Spat up about half-a-pint of florid blood last night. No evidence, either general or local, of tubercular deposition in the lungs. Stop calomel. Patient to have for drink iced "imperial."

9th.—Spat up a little frothy florid blood this morning. Pulse 96, soft; tongue moist, but denuded of epithelium.

10th.—Pulse 108; skin perspiring; throat still red, but free from deposit; no hæmoptysis since yesterday.

17.—Pulse 96; tongue clean and moist; appetite good. She is now quite free from pain, and was allowed to sit up in bed yesterday and this morning. Throat is now quite well, but cardiac murmur unaltered. She has been taking for the last few days half-an-ounce of lemon-juice, three times daily.

19.—This girl left hospital to-day, her health being apparently quite restored.

In this case, I am disposed to regard the endocardial murmur as being of long standing, and due to an antecedent cause. To this opinion I have been led by the absence of cardiac distress and excitement throughout her present illness, and by the soft character of the murmur itself. I have never witnessed an endocardial murmur of only a few weeks' standing, unaccompanied by precordial distress, and tumultuous action of the heart, in greater or less degree, and in which the murmur was not, at that period, somewhat harsh in character.

The occurrence of diphtheritic inflammation of the throat, and of hæmoptysis, without cough or other pulmonary symptoms or signs, is likewise interesting. In regard to treatment, I have found that this is precisely the form of rheumatic affection in which lemon-juice is most efficacious, viz.—where the inflammatory action is sub-acute, the swelling not considerable, pain not severe, and tongue free from deposit, red, and denuded of epithelium. In such cases there is, not unfrequently, epigastric tenderness, and irritability of stomach, and, under these circumstances, I prefer giving the lemon-juice in effervescence, but in excess of the saturating proportion.

#### ACUTE RHEUMATISM, WITH ENDO-PERICARDITIS, AND ERYTHEMA.

Mary Anne C., aged 40; married; has had ten children, of whom the youngest is sixteen months old, but at the mother's breast up to the date of admittance, viz.—May 2, 1867.

On the night of Wednesday, May 1, she was attacked with pain in the left ankle-joint and left knee. On the dorsum of the left foot, and anterior surface of the left leg, an erythematous blush appeared, accompanied on the follow-

ing morning with elevated patches of a deep red tint. The wrists and backs of her hands now became swollen, and covered with similar red elevated patches resembling erythema nodosum, and interspersed with a red papular eruption of the character of lichen; pulse 108, and full; skin hot and dry; precordial tenderness; first sound of heart diffused, soft, and ill-pronounced; left mamma distended with suck, and painful. An aperient of Rochelle salts, with tincture and infusion of senna, was directed to be given; the breast to be relieved by means of the breast-pump, and close attention given to the state of the heart.

5th.—A well pronounced frotement perceptible over the base of the heart to-day. At apex, first sound is soft and blowing.  $\frac{1}{2}$  grain of calomel, with 1 grain of James's Powder to be given every hour.

9th.—Burning heat of skin; tongue clean; pulse 108; cutaneous eruption unaltered. A loud double bruit, of a grating and superficial character, is audible over left base of heart. A soft systolic murmur is heard at the apex, and likewise feebly in the left axilla. Second sound not intensified in pulmonary artery. Up to this date the patient has taken altogether twelve grains of calomel; viz., the first six grains in doses of  $\frac{1}{2}$  grain every hour, and the remainder in similar doses given every third hour. She is now under the influence of mercury, being slightly salivated. To have a gargle of chlorate of potash and hydrochloric acid, calomel stopped, and aperient repeated. At her own request this woman was permitted to leave hospital on the 13th May, to resume her domestic charge. Her pulse had then come down to 90, swelling and pain had left her joints, and the eruption had partially faded. The apex murmur was still audible, but precordial tenderness no longer existed. The occurrence in rheumatic fever of an exanthematous, or a papular rash in the neighbourhood of the affected joints, is occasionally witnessed, and where there is great determination to the surface, such eruption may become general, and may lead to serious error in diagnosis. I recollect having seen a case of acute rheumatism in which, on the second or third day of illness, the entire body was covered with a semi-papular eruption, resembling the undeveloped stage of small-pox, and in which the diagnosis rested entirely upon the special implication of certain joints, and the presence of profuse perspiration.

The early detection of cardiac complication, as well as the satisfactory result of treatment, with small doses of calomel, frequently repeated, according to the method of Dr. Law, are likewise interesting. The class had the opportunity of observing in this case, from day to day, the gradual development of the stethoscopic signs indicating deposit upon the mitral valve, and upon the surface of the pericardium.

One of the cases of concussion is of much interest, as the injury is chiefly of the spinal cord. This, together with the details of the case of punctured wound of cranium, will be published when complete.

ST. GEORGE'S HOSPITAL.

ENLARGED SCROFULOUS GLANDS DISPLACING THE AORTA  
AND INNOMINATE ARTERIES.

Under the care of Mr. POLLOCK.

(Reported by Mr. E. C. RING, Surgical Registrar.)

Wm. J., æt. 18, was admitted on October the 8th, 1866, with a large mass of scrofulous glands in the neck. He stated that it made its first appearance fifteen months previously as a small lump near the larynx. There was a large lobular mass of glands in the left side of the neck, extending upwards as far as the mastoid portion of the temporal bone, backwards to the edge of the trapezius, and forwards to the lobe of the ear, and angle of the lower jaw. From this it extended downwards to within an inch of the tendinous origin of the sterno-mastoid, overlapping the muscle above, but lying behind it below. It extended deeply into the neck, pushed the pharynx and œsophagus forwards, and the trachea to the right. Its lower border was irregular, and ran from the margin of the trapezius, about three inches from the mastoid bone, obliquely downwards and forwards, to terminate at the tendon of the sterno-mastoid. The boy was pale and thin; he was ordered syrup of the iodide of iron, and cod-liver oil twice a-day, with ordinary diet, and a pint of porter; and the surface of the neck was to be touched with the actual cautery, in the form of a small button of iron, while hot, and to be repeated three times a-week. He had a slight feverish attack on the 19th, and the application of the hot iron was discontinued. The attack subsided in a few days, and the cautery was resumed. The mass now began to diminish slightly in size, but the glands on the opposite side of the neck began to enlarge, and cough and shortness of breath came on. All active treatment was therefore discontinued, and on the 28th he was transferred to the physician for hæmoptysis

and other chest symptoms, under which he gradually sank, and died on the 10th of February, 1867.

Mr. T. P. Pick, Curator of the Museum, has furnished the notes of the post-mortem examination:—

*Externally.*—The body was emaciated; the legs were œdematous; there was a large lobulated swelling on the left side of the neck.

*Thorax.*—There was a quantity of fluid in the left pleural cavity, and the lung on this side was compressed and destitute of air; the right lung was œdematous and full of frothy fluid. The pericardium contained a little fluid. The left side of the heart was open; the right contracted; the valves and structure were healthy.

*Abdomen.*—The liver was slightly lardaceous; the acini well-marked, and semi-transparent; the spleen was natural; the kidneys were large, smooth, and mottled; no amyloid reaction.

*Neck.*—The swelling in the neck was found to be due to tubercular infiltration of the cervical glands; these glands extended in every direction upwards to the occiput, backwards to the spinous processes; inwards between the pharynx and vertebræ to the right side, and downwards into the thorax; in this latter situation they had pushed the aorta over to the left side, so that the innominate artery was elongated, and crossed the trachea just at the point where tracheotomy is performed. The pneumogastric and laryngeal nerves were compressed and flattened.

CURRENT LITERATURE.

*The Waste of Infant Life*, by J. B. CURGENVEN, M.R.C.S.

This is a pamphlet, the substance of which was read at a meeting of the Health Department of the National Association for the promotion of Social Science, by Mr. Curgenven, Honorary Secretary of the Harveian Society. His object was to show the proportion of preventable infantile deaths, both those which are occasioned by carelessness on the one hand, and those which are intentional on the other, whether directly inflicted or brought about at length, and as surely by designed neglect. This is a subject which has excited considerable attention of late in France, in consequence of the stationary condition of the population generally, and the fact that in some parts, instead of the numbers remaining stationary, they are evidently on the decline. At present, we are far from having reached so lamentable a state in this country. Every return which is made, shows a constant increase, more or less, in each locality of these islands. Still, it is a fact, that there are causes in operation amongst us which augment the mortality of infants, and which, by proper care, might be removed, at least, their influence lessened in a very appreciable degree. The author shows the different causes of the death of infants under one year of age during 1864.

“The deaths of children from dietic diseases, and diseases of nutrition, were as follows:—Want of breast milk, 1233; privation, 8; atrophy and debility, 20,923; thrush, 957; diarrhœa, 9818; convulsions, 20,821; teething, 2142. Thus we see that there died of these diseases in this year, 55,902 children under one year of age.

“The next class of cases is that of acute diseases of the respiratory organs. The deaths of children under one year of age from these diseases during the year 1864, were as follows:—Laryngitis, 363; croup, 880; bronchitis, 7400; pneumonia, 8382; lung disease, 1090; total, 18,415.

“The number of children who die of hereditary disease is not so great as is generally imagined, since these diseases are more fatal in youth and advanced life. The numbers of children who died of the most common forms of tubercular diseases during 1864, under one year of age, were as follows:—Hydrocephalus, 2836; tabes mesenterica, 2659; scrofula, 514; phthisis, 1076; total, 7085. Hereditary syphilis, 1089.”

By comparing these figures, it will be seen that the number of children who die under one year of age, from diseases which follow defective nutrition, is more than twice the number of those who die from diseases not so produced. Such disproportion is not to be wondered at, if we think for a moment of the supreme importance of proper nourishment for an organism so recently developed. Nature furnishes it with subsistence suitable to its tender age, and if that supply through accident should be stopped, or through omission be discontinued, the unhappy little being must necessarily suffer, perhaps oftener die. As the writer observes :—

“The infant’s stomach and power of digestion is adapted only for what nature intended it—the digestion of its mother’s milk ; and any departure from this adaptation of nature involves derangement of function, mal-assimilation, failure of nutrition, disease, and death. What would be thought of the farmer, and what would be the result to his stock, did he attempt to rear his calves and lambs on a pap of chopped hay or grass ? Yet this is what is done with thousands of children. Instead of milk, their natural food for the first nine months of their lives, they are given a pap of bread or some farinaceous food, which is just as injurious to them, as the pap of hay would be to the calves.”

Now, how comes it that we find so many infants deprived of their natural means of support ? It might be expected that the maternal instinct would be sufficient to prevent such anomaly, and secure to these helpless little beings their undoubted rights. “Can a woman forget her sucking child ?” Ordinarily not. But there are incidents and conditions of society in the ever changing combinations of human life, which alter strangely the order of nature, and interfere with proprieties the most legitimate. We can but hint them by another short quotation—

“The mother possibly has no breast-milk for her child, or she wishes to go out to her work by day ; or it may be an illegitimate child, or the child of a wet-nurse, placed in the care of a stranger ; or the mother may be in a higher rank of society, and desires to have her time for herself and her friends. Whichever it be, the case is the same. The child is hand-fed from its birth, or at all events from the first three or four weeks.”

One more cause of this neglect of infant requirements is mentioned by the author in closing his remarks. It is one which has come under our observation more than once, and which we have long thought a proper subject for authoritative interference. We refer to “burial clubs,” respecting which we have the following statistics :—

“According to the official figures, 18 in 100 children of the upper class annually die in Preston before attaining the age of five years ; in the middle-class, 36 or 37 per cent. In this same district, while infants of labouring men, outside the clubs, die at the rate of 36 per cent. before reaching five years, children of the same class who are insured in the burial clubs, die at the rate of from 62 to 64 per cent.”

Looking, then, to these particulars brought under our notice in the pamphlet before us, nothing can be more proper than the suggestions of the author. He considers that some means should be adopted to forestall this “waste of infant life,” and that the attention of the Coroner should be more frequently directed to the deaths of children, especially those which take place within their first year. Greater facilities, he thinks, should be given him for ascertaining the causes of death, and the circumstances under which it took place, so that he might be able to decide whether it was unavoidable, or whether blame rests any-

where, and if so, on whom. We have written and quoted more than we should have done, had we not felt that the subject is one of importance ; and we commend the pamphlet to all who feel an interest in lessening the evil to which it refers.

In the last number of the *Royal London Ophthalmic Hospital Reports*, Dr. Hughlings Jackson contributes a paper entitled “A Physician’s Notes : Ophthalmology,” the chief object of which is to urge physicians and ophthalmic surgeons to do more work together. Dr. Jackson, without repudiating differentiation in practice, is desirous of seeing more unity of aim in the cultivators of medical science, and his paper is well adapted to promote that object. The controversy respecting specialism has been waged with such acerbity that it is quite refreshing to come across a paper in which these points are treated from a scientific point of view. We make the following extract with regret that we have not more space at our disposal, but our readers can procure the whole paper, together with a mass of other valuable matter from various sources, in the *Journal* named :—

“Were I free to work in this metropolis at the physiology of movement, from gross muscular movements towards thought, in the way I should prefer—supposing to begin with an ordinary general medical and scientific knowledge—I should study first in the wards and in the out-patient room of a general hospital, such symptoms as hemiplegia, chorea, and epilepsy ; next, at an Ophthalmic Hospital paralysis of the cranial nerves and defects of sight. Next, at a special hospital, for such symptoms as those of locomotor ataxy, and certain epileptiform seizures. Then at an Orthopedic Hospital for infantile paralysis and for so-called contractures. Now I would study specially deviations from healthy movement of the eyeballs, and the rudimentary delusional effects they cause. I would, after this work, return to the General Hospital, to study defects of speech, delirium, apoplexy, coma, &c. Varieties of defects of speech I should compare and contrast from difficulty of articulation to incoherence. At this juncture a careful study of laryngeal and throat diseases would be most desirable.

“Of course if any one were to work at different sections of medical practice, so as merely to add isolated series of facts to one another, he would really make little progress in cultivating his own mind. Such a man would dwell with exaggeration—hurtful to his own organization of medical knowledge—on amaurosis as a defect of sight, and too little on it as a defect of a highly specialized part of universal sensation. He would not improbably neglect altogether such symptoms as defects of smell, which defects, however, are really quite as significant incidents in the revelations which disease makes of function as defects of sight are. Such a student would be altogether unprepared for the last and the very highest medical study viz., of Insanity. Special work at diseases of the mind should, I feel convinced, be begun only after a large real experience of all the special phenomena of motion and sensation that damage to any parts of the Nervous System does or may give rise to. I say a real experience, as I suppose a collection of numberless facts, however accurately gathered, is not held to be of itself a real experience. Unless a man can put the particular phenomena he himself sees under more general Laws, or unless he tries to do this, he can scarcely be said to know or to be studying a thing in any very valuable sense. The knowledge the ophthalmologist has of muscular disorders of the eye ; the knowledge the physician has of defects of articulation, of chorea, and of epilepsy, and that the psychologist has of incoherence and delusions should aim to be physiological\* units, each different but each related to a wide common know-

\*Physiological unit is a term introduced by Herbert Spencer. To understand the wide meaning of this term, Mr. Spencer’s work on Biology must be studied.

of "Aphrodision," by ROBERT JACOB JORDAN, at the end of which are printed in full the diplomas of the London College of Surgeons, and the Edinburgh College of Physicians. Two of these were sent through the post to one house. It is superfluous to enter on the subject of the contents of this production. It would be an insult in a Medical Journal to ask whether the circulation by the post of such pamphlets could be countenanced by the Profession. The great corporations which derive their incomes from the medical men of the kingdom owe a duty to themselves and to their members. Too long, indeed, has apathy prevailed in high places; and the tardy resolution to enforce the law will be looked upon as a concession to pressure from without which might long since have been made. It is undeniable, that acts likely to bring every member of our body into disgrace have too long been suffered in silence by our natural guardians. The corporations, not content with pushing an unworthy rivalry to extremes, and touting for customers in a manner that a petty tradesman would scorn, have laughed at the oft-repeated protests of an indignant press, and left unnoticed the remonstrances of their own members. Is this prosecution the announcement of a new era? May we hope that for the future a sincere attempt will be made to put down all forms of quackery which sap the foundations of public morals, and form the foulest excrement of the body medical? If so, well and good, and the corporations may yet make their existence tolerated. There is ample room for them all in this occupation—the fields are white with the harvest they may reap. Let them put in the sickle at once.

It may be noted that this is not the first time we have called attention to JORDAN and his doings. We fully discussed him and his works in a leading article in our issue for 7th March, 1866.

### Notes on Current Topics.

THE NEW SANITARY ACT.—Our readers are aware that under the 38th section of this Act, which was passed last year, a person afflicted with any infectious disease who unnecessarily exposes himself and endangers others, may be fined on conviction before a Magistrate. There can be no doubt that these diseases are communicated in hundreds of instances, in which they would never have occurred but for the neglect or carelessness of those who suffer from them. It is impossible in all cases to guard against such imprudence; still a great deal may be done to prevent the recklessness of individuals, and we hope the parish authorities will avail themselves of the power which the legislature has put into their hands. A case lately occurred of a man named Cook, who was under treatment for small-pox, in the "contagious ward" of the Aylesbury Union Workhouse. Contrary to the orders of the Medical Officer, he had twice made his escape, wishing as he said to see his friends. The first time he passed along the high road, through

several villages, and at length reached Wingrave, where his friends resided. Here he entered several houses, and terrified the inmates, and the inhabitants generally, who had him conveyed back to the Workhouse. Again he contrived to escape, when the Guardians interfered and brought the case before the Magistrates, who severely reprimanded such conduct, and fined him 5s., and 12s. 6d. costs. This was a nominal fine, but the magistrates let it be known that they should deal much more severely with any such case that might in future come before them.

THE VACCINATION BILL.—We do not feel by any means enthusiastic about the measure now before Parliament. Its warmest supporters will probably, on reflection, acknowledge that it is full of serious defects. Compulsion in this country is not easily carried out in anything that bears the slightest resemblance to our infringement of the liberty of the subject, and there are always to be met with partisans who would defend the right of a father to let his child contract and propagate small-pox. We have tried a half measure, and found it an egregious failure. Unless we are prepared to enforce a stringent compulsory act we may as well let the matter remain where it is. Passing acts to let them be ignored is a weakness calculated to bring legislation into contempt. Mr. Rumsey believes in *indirect* compulsion, and this is certainly practicable without the intervention of Parliament. Suppose no child were admitted into schools and factories without the marks of successful vaccination on the arms, or a medical certificate that the operation had been properly performed. A little union among owners of factories and managers of schools would soon effect this. Suppose the heads of families insisted on the same qualification in engaging servants. Such a custom would do more than half-a-dozen clumsy acts of Parliament, laden with the machinery for producing an inexhaustible supply of useless unpaid for certificates. If we are to have vaccination by legislative enactment, the first provision should be the employment of the profession with adequate remuneration. To effect this we want a dozen first-class medical men in the House of Commons.

MORTALITY OF MADRAS.—Wherever we have the means of forming a judgment, we invariably find that the diseases incident to humanity obey the same laws and are followed by the same consequences all the world over. In this country or another, it matters not, the sanitary reports vary only in numbers or proportions, consequent upon the different condition of the population to which they refer. Dr. Smith, the secretary of the Sanitary Commission in Madras, has issued his report for 1865, but as registration there is not compulsory, the numbers may not be strictly accurate. Still, they show that the same causes operate there as well as here, and produce the same effects. It appears that the health of that town during 1865, was in a better state than at former periods. The number of registered deaths was 11,216, being at the rate of 26 per 1000 of the population. The adults' deaths were chiefly from cholera, small-pox, fevers, diarrhoea, and dysentery, which produced a proportion of 11 per 1000. In London the proportion of deaths from these diseases was only 4 per 1000 in that year. Some little allowance must be made for this inequality from the fact stated by Dr. Smith, that miasmatic diseases in Madras take the place of tubercular diseases in London. Small-pox destroyed this year 399 less than the average. It seems that the Hindoos object to vaccination on religious grounds, and consequently died in

greatest numbers from this cause ; though, on the whole, vaccination is becoming more general, and has been one means of lessening the mortality from small-pox. From cholera there was a small number of deaths compared with previous outbreaks. In 1862 it destroyed 3635, and in 1863, 1684, whereas the number this year, 1865, was only 944. The number of deaths from dysentery was large, amounting to 1159. Of children dying under one year of age more than one-third was from convulsions, the proportion from this cause being 1 to 8 of the whole population, while in London it was 1 to 30. The effects of climate on the European as distinct from the native population, is shown as follows:—Deaths from all causes, Europeans and East Indians 27·8 per 1000 ; Mahomedans 25·5 ; Hindoos 26·2. Thus we find that the mortality is greater there than in London. But this may be accounted for on the very same principles as are recognized here. It appears from the report that bad drainage, impure water, foul air, overcrowding, and filth, have mainly contributed to swell the mortality of the town.

**DEATH IN MAURITIUS.**—A fearful mortality has occurred in this island. Fever has been raging dreadfully since the beginning of February, and has continued its ravages up to the middle of last month with unabated virulence. Heavy rains fell on the 14th, accompanied by strong breezes from the south-east, which lowered the temperature, and the cases have been fewer in consequence. It is hoped that this abatement will continue. The following is the mortality from 1st to 15th April :—

	DEATHS.	POPULATION.
Port Louis . . . . .	2,879	80,000
Pamplemousses . . . . .	931	60,000
Riv. du Rempart . . . . .	316	21,000
Flacq . . . . .	97	46,000
Grand Port . . . . .	73	41,000
Savane . . . . .	49	23,000
Black River . . . . .	407	19,000
Plaines Whilhems . . . . .	146	31,000
Moka . . . . .	172	20,000
	5,070	341,000
From 10th to 28th February	2,061	
In March . . . . .	6,433	
	13,564	

The disease has been very general. There was scarcely a house in Port Louis but what was visited by it in the beginning of April. But we find here, as we have frequently remarked elsewhere, that neglect of proper hygienic measures, invariably brings its own lamentable effects. In this instance, the accounts inform us, that “on estates where there is care and discipline, the mortality has been small, but it has been largest where Indians have been allowed to agglomerate without any control, and without the enforcement of any sanitary discipline.” Quinine has been so scarce that “three ounces were publicly sold at £12 the ounce !”

**DR. LIVINGSTONE.**—Nothing certain can yet be affirmed concerning this enterprising traveller. As is usual in all such cases, incidents occur which at one time raise our expectations, and at another seem to confirm our worst fears. Latterly we have felt totally in the dark respecting the fate of the intrepid explorer, and almost gave him up for lost ; but a few days ago a ray of light appeared to break through the darkness, though, we confess, very feeble and flickering. We quote from the *London Review* of Saturday

last : “On Monday evening Sir Roderick Murchison informed the Royal Geographical Society that he had that day received a letter from Tansibar, informing him that an Arab trader had just arrived from Lake Tanganyika, on which he had met a white man ! It is well-known that the Tanganyika was the point which Dr. Livingstone was striving to reach when it is said he was murdered by the Mazite. Sir Roderick stated that no white man but Livingstone had left the shores of Africa for the Tanganyika ; and who could the white man whom the trader met there be but the illustrious explorer whose death has been reported to us ?” The reports hitherto received are not to be depended upon, and we must wait the result of the proposed expedition before our uncertainty can be removed.

**SIR WILLIAM LAWRENCE.**—This veteran surgeon, whose baronetcy we recently announced, has been seized with paralysis. The seizure took place within the walls of the London College of Surgeons, just as he was about to enter the examining room and take his place at the Board. It would be superfluous to add that every assistance was rendered the eminent Sergeant-Surgeon to the Queen.

**OUTCASTS.**—Those to whom this significant title applies, exist in every walk of life—from the mansions of the rich and the lowly cottages of the poor, we see them continually wandering, with none to care for them, none to take them by the hand to give them a little reasonable counsel, which would do more towards their reclamation than all the threats of punishment, police courts, or reformatories put together. But the class for which we would now especially plead is that denominated “the street arabs.” We cannot pass down a street or through a square of the metropolis—and London is but a type of most other large towns—without meeting a few of these juveniles, miserably clad, oft in a state of semi-nudity, whose pallid faces, filthy bodies, and squalid figures, but too truly tell their tale of woe ; and none better, perhaps, than the medical man can bear witness of the sufferings and disease they undergo. Almost as soon as these little creatures are able to put one foot before the other, we find them brought out or sent out by their unnatural parents, and for what ? To gain each of them some small pittance, either by begging or by stealing (it matters little in the scale of their social economy which), from whom ’tis quickly transferred by their wretched guardians to the till of the nearest *gin palace*, thus leaving the poor little labourers, day after day, at a time in their pitiful existence when they most need nourishment and maternal care, without food, except what they pick up in the streets and market-places ; and night after night, with but the lodging and rest the cold damp ground or a door-step can give, these wretched units in creation, grow up—at least those for whom disease has not prepared a grave—into a large band of big boys and girls, and thence into manhood and womanhood—to stain the annals of crime with abominations too horrible even to contemplate. Now, we would beg to offer one or two suggestions for the consideration of Parliament, which, for ought we know, may have already suggested themselves to some honourable members, with many an anxious thought for their solution. Cannot something be done to alleviate the abject misery consequent on this pestiferous state of things ? Without hospitals crammed, our police and criminal courts filled, and our prisons inundated—would it not be much cheaper to the ratepayers and the country at large, that an act should

be passed—vesting each parish with authority to place these little starvelings seen wandering about the streets, in a home provided for the purpose, teach them to read and write, and at a certain age—say twelve—let the Government take them in hand, and train them for the service of the country. There cannot be a doubt that a system having none but philanthropic motives in view, with the principles of hygiene to its aid, would eventually work well. True, the expense the movement would first entail would not be inconsiderable, but it must soon meet its counterpoise—in a decrease of local taxation for police, and prisons—with increased confidence in the safety and respectability of our thoroughfares, to say nothing of its moral bearing upon the population generally.

**WORKHOUSE INFIRMARIES.**—The Association for the Improvement of the London Workhouse Infirmaries have lately held a meeting, at which Lord Grosvenor presided. The object was to consider what course should be taken by the Association, now the New Metropolitan Poor Act was passed, and the objects chiefly attained for which the Association had at first been organized. It was agreed to discontinue active operations, but, at the same time, to watch the Act of 1867—and to hold themselves in readiness to take their former position again should occasion require. They have a balance of nearly £100 remaining, as their operations have been carried on gratuitously. Mrs. Beeton's case, whose evidence was so important, and who, it was thought, had "injured her prospects by her spirited conduct"—was referred to a sub-committee. It was decided likewise, "that a committee should be formed to consider in what manner the eminent services to the cause of the London sick poor of Mr. Ernest Hart should best be marked." Thanks were voted to "various members of Parliament for their attention to the Act now passed," and to the press, "for the support given to the cause which the Association had so successfully carried out."

**GREENWICH HOSPITAL.**—The question between the Admiralty and the Seamen's Hospital Society respecting Greenwich Hospital, to which we have devoted several articles, has been brought to a crisis. Dr. Bristowe and Mr. Holmes having been requested by the authorities to inspect the building, and advise as to the eligibility of its portions, have presented a report pronouncing in favour of Queen Mary's quarter. The Society must therefore accept this, or build another hospital, for there can be no pretence that these gentlemen were not eminently qualified to offer an opinion. Our proposition to create a large naval medical school at Greenwich is not, perhaps, likely to be accepted by the Government. Nevertheless, we maintain that such a course would conduce to the efficiency of the naval medical service, and be of the utmost value to our sailors. There is the building—why should it not be thus utilized?

**SPECIAL HOSPITALS.**—The only fair way of putting down special hospitals—on which some of our contemporaries have lavished so much abuse—is the plan now being carried out at several of our large hospitals, of creating a number of special departments. No one can be blind to the value of such a division of labour, nor deny that this is the best plan for securing the efficiency and completeness of medical education. In all the general hospitals there is abundant material for the establishment of a most complete series of special clinics. At the same time, until

such departments have been proved to work well, it is useless to decry infirmaries for special diseases—particularly while the medical officers of the larger institutions accept posts at the smaller. Moreover, a large amount of talent exists outside the recognized schools, and talent is apt to be restless, impatient, and ambitious. Then, as it often secures influential and wealthy friends, it is sure to create a field for its own exertions. The only natural remedy for this is for the larger hospitals to attach to themselves the talent they develop. The majority of the hospitals have handed over their departments to members of the existing staff—already overworked—leaving out in the shade a number of excellent men who might well have been invited to join. It is rumoured, as we some time since mentioned, that, at St. Bartholomew's—decidedly the most conservative of the London hospitals—the departments will be given to men not on the present staff. We trust it may be so. How well the plan has worked at Guy's is notorious, and we believe that each of our schools may, with advantage to students and patients alike, enlarge its staff. There is no want of material for study, nor of men ready to take up the work. Our hospital men are, indeed, ardent workers, but most of them have already too much on their hands. Why should not they take the initiative, by urging on managers the necessity of enlisting all the talent that now has to make its way by founding new institutions? Until something of this kind is done, no amount of abuse will put down the special hospitals. What these little institutions can achieve is to be seen in the present state of ophthalmology. Why should not the general hospitals have had the glory of what has been done in that special department? And why should the same question be left to be put about other departments, a few years hence?

**SUNSTROKE.**—During the late hot and sultry weather, two persons have died from this cause. The first was a policeman who, after being exposed all day to the sun, suddenly fell dead upon his beat. The other case was a man employed in the Imperial Gas Works. His business was to take coals in a hand waggon from the store to the retort, in doing which he passed repeatedly under a skylight through which the sun shone very powerfully. Suddenly he became giddy and appeared as if he was drunk, and expired before medical aid could be obtained. Inquests were held by Dr. Lankester, and verdicts according to the evidence were given.

**TAR OR OIL-CLOTH.**—A man has been sentenced to ten years' penal servitude for setting fire to his house with intent to defraud an Assurance company. The theory of the prosecution was that he had placed in readiness and set fire to a quantity of tar. Dr. Odling found what he considered the results of the sublimation of tar. For the defence, it was argued that these results were due to the consumption by the fire of a quantity of oil-cloth, and Mr. Crookes, F.R.S., and Mr. Heaton, of Charing-cross Hospital, were called in support of this view. A number of other questions complicated the issue, but we call attention to this merely to mark the discrepancy in the opinions of eminent chemists as to the results of the combustion of these two common substances. The subject may be worth further investigation, and the issue, though not one of life and death, is, in a medico-legal point of view, of the utmost importance.

**A NEW SUBSTITUTE FOR CHLOROFORM.**—The subject of anæsthesia is yet in its infancy, and we may therefore be prepared at any time to chronicle further discovery. Dr. Protheroe Smith has made some experiments with tetrachloride of carbon ( $\text{C Cl}_4$ ) the inhalation of which he finds produces anæsthesia in a very short time, while the effect passes off equally rapidly. It is further stated that it does not produce some of the unpleasant symptoms that it not unfrequently attend the administration of chloroform. Dr. Protheroe Smith has given it in several cases, and we sincerely hope the favourable opinion formed of it may be confirmed by further trial. We can well afford to add to our means of subduing pain and producing sleep.

**CHOLERA YEAST.**—The investigations of Herr Klob and Herr Thomé, originally detailed in Virchow's *Archive*, point to the development of an enormous quantity of a vegetable growth in the intestinal canal of cholera patients. At a recent meeting of the Pathological Society of London, Mr. Simon exhibited a specimen of the plant which had been given to him by Herr Thomé, during his recent visit to the Continent, to attend the Cholera Conference just held at Weimar. Mr. Hulke and Dr. Sanderson were appointed to report on the subject, and we may, therefore, look with confidence for early and reliable information.

**THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.**—The annual meeting of the College, to elect a Council and office-bearers for the ensuing year, will take place on the first Monday in June, and on that day the annual meeting and dinner of the Irish Medical Association, and the meeting of the Royal Medical Benevolent Fund, will also be held. We understand that Mr. G. H. Porter, Surgeon to the Meath Hospital, and for many years an Examiner in the College, will offer himself for the Vice-presidency, which will be vacated by Mr. Banon, in his presumed elevation to the Presidency. Mr. Butcher, the out-going President, will offer himself for election to the Council, in the room of Dr. Pentland, of Drogheda, who, we are informed, has expressed his intention of withdrawing. The only candidates as yet mentioned in addition to the existing Councillors, who will offer themselves for re-election, are Dr. Zachariah Johnson, and Dr. S. L. Bigger, of Kilkenny. We learn that Dr. Mackesy has been induced, by the solicitation of his friends, to reconsider his intention of retiring, and will ask for re-election to the seat which he now occupies.

**A SHOWER OF ORANGES.**—The Dublin gossips have been greatly amused and puzzled by a supposed celestial precipitate of oranges in the streets of their city. It appears that a considerable number of small dry fruit—resembling an orange in appearance, but only the size of a nut—were picked up one morning last week by different people in all quarters of the city, and, on further search, a further supply were found in the most unlikely situations—on the roof of the Bank of Ireland, the Observatory of Trinity College, and of a railway terminus, and, especially, in the neighbourhood of St. Patrick's Cathedral they were to be found. At first it was believed that they had been thrown out of a large drug store in that locality, and distributed by the winds, and by the aid of children and birds, all over the city; but the finding of them in places where, at least, the children could not go, gave rise to the idea that they fell from the clouds—a theory which is earnestly disputed and vigorously maintained. As yet

the matter (not the berries) has only passed from mouth to mouth, in conversation, but we understand that it will form subject for discussion at the next meeting of one of the learned societies of Ireland.

**THE LIMERICK UNION AND ITS MEDICAL OFFICER.**—We learn that the Poor-law Commissioners have declined to call upon Dr. O'Sullivan to resign his appointment as Assistant-Surgeon to the workhouse, or to dismiss him by sealed order. The public spirit which has actuated the Commissioners in their protection of Dr. O'Sullivan from the malignity of the clique who wished to annihilate him, does credit alike to the wisdom of the Legislature in providing for such interposition, and to the Commissioners themselves individually. We cannot, however, but deeply regret the present circumstances under which the Union is left, without the use of a skilled resident, while the Officer, whose duty such attendance would be, is in open antagonism with his employers. We venture to suggest that Dr. O'Sullivan might, without bating any of his self-respect, express his regret at having been betrayed into disrespect towards ladies whom, we are sure, he would be the last to desire to offend, and that the Board of Guardians, in consideration of the exigencies of the situation, and of the sick poor who suffer the penalty of this disagreement, might reinstate Dr. O'Sullivan in the discharge of his functions. Both they and he owe it to their public duty to sink personal feelings of acerbity in maintaining the efficiency of the institution. In connection with this question, we cannot but remark, with extreme regret, the fact that, amongst those who were most prominent in the effort to throw dirt in Dr. O'Sullivan's character, professional and moral, was a member of our own Profession. When such quarrels between Boards of Guardians and their Medical Officers crop out, as they too frequently do, it is expected from the good taste, if not from the personal friendliness of a medical brother, that he will endeavour to avoid befouling his own nest, by displaying an unseemly animosity towards his co-professional. Unfortunately, as in Cork, so here the expectation has not been fulfilled, and we need only express our conviction that the "Dr.," who, by his interference in what concerned him not, brought upon himself the unqualified censure of the Commissioners, and originated the *melée* which followed, covered himself with no glory, even in the opinions of those with whom he associated himself, and whose cause would have been stronger without the intrusion of the medical champion at all. We would prefer, on such occasions, to see medical men a little too deaf to the call of duty, than a great deal too ready to join the yelping chorus of "Hit him again, he has no friends."

## Summary of Science.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES R. C. TICHBORNE, F.C.S.L., F.R.G.S.I., &c.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

(Continued from page 462.)

### PHARMACY.

#### CULTIVATION OF MEDICINAL PLANTS.

MR. HANBURY, in an interesting paper addressed to the Pharmaceutical Society, impresses upon them the necessity

of the cultivation of medicinal plants, and points out that the supply of drugs, which are without culture, is of a necessity fluctuating and precarious, and that whatever vegetable substance is needful to man, he must ultimately cultivate the plant producing it.

#### THE REDUCED SUPPLY OF SCAMMONY.

The demand for cotton consequent on the war in the United States, stimulated the culture of that crop in Asia Minor; and, as the growing and picking of cotton required many hands, the wages of the peasantry so greatly advanced, that it was less profitable than usual to collect scammony, and hence a reduced supply and enhanced price of that drug.

Political convulsions impeding the freedom of commerce also operate extensively in diminishing the exports of a country, and to such cause may be attributed the late high price of snake-root, senega, and other drugs of the United States. The increased value of jalap is probably due to the unsettled state of Mexico.

East Indian kino of the best kind is a drug which, during the past few years, has become exceedingly scarce, and, we might say, has ceased to be important. Now, this sort of kino, which was produced near Tellicherry, was, a few years ago, brought into competition with kino, from another district of India, which, though considered inferior in quality, was freely sold, and at a much lower rate than the old drug. The price of Tellicherry kino consequently fell enormously, and it would seem that the drug has ceased to be brought into the market.

Ipecacuanhæ again, has doubled in value since 1850, owing partly, it is said, to the extirpation of the plant from old habitats, and the consequent necessity of collecting it from new and more distant localities. The rarity of a drug, or its total disappearance, is due, in some cases, to an improvident and ruinous method of collection. Thus, a century ago, there was still found in commerce *loxa bark* that had been stripped from tree trunks of no mean dimensions, and some such bark which we have seen, has a thickness of a quarter of an inch, and is rich in alkaloids. At the present day, old trees yielding this species of bark is unknown, all the *loxa bark* of modern commerce being derived from shrubs, which are stripped even to their smallest twigs, therefore it has been more advantageous to grow sugar, coffee, cotton, and cacao, than to collect drugs. South American *elemi*, liquidambar resin, *tacamahaca*, *caronma*, *Winter's bark*, and *contrayerva root*, have now disappeared, and oil of rhodium is now an artificial compound. *Sagapenum* and *opopanax* is very rarely imported. Other drugs require better care in their cultivation. Two are especially mentioned by Mr. Hanbury, viz.—*hemidesmus root* and *chiretta*.

We may add to this list many other drugs which are gradually becoming scarce and valuable, not the least important of which is *rhubarb*.

#### A NEW ALKALOID FROM OPIUM.

Messrs T. & H. Smith describe a new alkaloid that they have isolated from opium. The name is *cryptopia*. It is contained in the weak spirituous washings from precipitated morphia. Strong sulphuric acid produces a blue colouration with this base.

#### PRESERVATION OF VEGETABLE SPECIMENS.

To preserve herbs by means of carbolic or phenic acid, it is sufficient to place them in close cases, containing a little tube closed with cotton, which is filled with benzine or carbolic acid. The benzine should be renewed twice a-year.

Some naturally give the preference to phenic acid, because benzine vapour is extremely inflammable.

Phenic acid is sold at a low price; its vapour destroys insects completely, and its solubility in alcohol permits the use of it in preference to the solution of corrosive sublimate.

We give the preference to phenic acid for the preservation of plants.—*Journal de Pharmacie*.

#### ANALYSIS OF SANTONINE LOZENGES.

By M. Reickher.

The process is founded on the solubility of the active principle in chloroform, and the insolubility of the sugar.

The author employs a tube about twenty-four inches in length, and measuring about twenty-four cubic inches in capacity.

Having well dried this tube, the author placed in it a cotton cushion, on which was piled up the substance from two lozenges reduced to a powder; they had been previously well dried and weighed.

He secured the powder by another cushion, and fastened one end of the tube in a balloon dried at 100° and weighed, and then poured thirty grammes of chloroform in the open end. When all had passed he evaporated a dozen drops, and collected them on a watch-glass, at a gentle heat, to see if there was a residue of santonine. The balloon must be freed from chloroform in order to obtain the santonine which is readily weighed.

The author has experimented on many santonine lozenges. The results have been variable. They have often been *nil*, and have never exceeded the value of half a grain. The *modus operandi* pointed out in this experiment may be of use in the analysis of other medicinal lozenges.

#### PHOSPHATES.

M. Collas, says F. Moigno in his weekly letters to the *Chemical News*, continues his researches upon the phosphates in general, and, in particular, the phosphates of lime. M. Collas has, in fact, demonstrated that the phosphate of lime becomes a decomposing agent of putrefaction, and, after death, hastens the dissolution it was the means of preventing during life; it also favours the development of new existences.

In pregnant women or wet-nurses there is an absence of phosphate of lime in the organism, and the presence in the urine of sugar.

M. Collas advises the following preparations:—

1. *Solution of Phosphate of Soda*—namely, eight grammes of phosphate, in spring-water. It is to be taken instead of mineral waters, mixed with wine, and at the rate of two or three glasses per day.

2. *Phosphoric Lemonade*.—Phosphoric acid two grammes, in a litre of spring-water, taken from time to time as a beverage; hydrated phosphate of lime milk; ordinary hydrated phosphate of lime, thirty-six grammes; water, one hundred grammes, mixed together in a mortar, and passed through a strainer or fine sieve, one, two, or three spoonfuls, to be taken daily, especially in soup. This is the best way of administering phosphate of lime to rickety children. The phosphate of soda has the property of converting sugar into glucose in presence of carbonic acid.

#### OLEO-RESINOUS EXTRACT OF CUBEBS.

The oleo-resinous extract of cubebs is generally prepared by treating the pepper, reduced to a coarse powder, by alcohol at 60°. M. Constantine Paul prefers to this extract one which is obtained by acting successively on the cubebs by water, alcohol, and ether. The extract thus obtained contains all the active principles of the pepper of cubebs. The volatile oil, the balsamic resin, soft and acrid, and the cubebene. This extract is of a deep olive-green colour, a thick syrup consistency, and a strong ethereal perfume, in which we recognise, however, the proper odour. The savour of it is fresh and pungent, like that of mint. This extract corresponds to ten times its weight of the powdered drug, and he employs it enclosed in capsules which contain 75 grains.

#### PHARMACY IN THE PONTIFICAL STATES.

Translated from the French Notice by M. Adolphe Schaeuffèle, *Journal de Pharmacie et de Chimie*.

In the Pontifical States the Pharmaceutical Profession is only accessible to young students who have finished their literary studies, comprehending rhetoric and philosophy. The term of pupils is longer than in France, lasting for

several years. After having followed a special course at Sapienza (Sorbonne de Rome), they submit to an examination to obtain the diploma of "*Pharmacien*," the first-class, and the privilege of a free practice.

For the candidates for a diploma of the second-class the tests are much less important than for those who aspire to the first-class, and they are examined by a special commission, the institution of which recalls our ancient medical jury.

The first-class only have the right of preparing official medicines; those of the second class should apply to them for those preparations, which they are prohibited from making.

The prices of medicines are fixed by an obligatory tariff. The disputes between the "*pharmaciens*" and their clients are regulated by the Medical College of the Province.

The number of officials is limited. They reckon at Rome sixty "*pharmaciens*" for two hundred thousand inhabitants. The Roman "*pharmaciens*" have some religious orders amongst them. Several religious communities have enjoyed for some time the right of selling medicine to the public—the Brotherhood of St. Jean de Dieu, the Carmelites, and the Jesuits; but unless their laboratory was conducted by some of the Order who had obtained a first-class diploma, they would be unable to exercise the privilege. Several Prelates have assured me that the authorities have shown themselves very cautious in "granting" the privilege of selling medicine to the community.

The official establishments at Rome are generally well kept; there is found in them a collection of paintings, objects of art, bronzes, &c.

The medicines are put into vases resembling ours, and placed in glass cases; they are arranged according to their therapeutic properties, and not on account of their pharmaceutical appearance. This arrangement appears very important to us in a practical point of view. In case of error, the physical result is always more or less analogous with that which the physician would attain.

The use of purgatives is very general amongst the Romans, and in each house there is placed a glass at their disposal, in which they prepare for themselves their medicine—viz., a spoonful of calcined magnesia, 30 gramm of a sweetening syrup, according to taste, and a bottle of seltzer water.

The Roman doctors are generally badly paid, and it is in these establishments that they are most frequently sought for, consequently there is reserved for each of them in the "*pharmacies*" of his district an arm-chair, underneath which is placed a point of iron, which is fixed in the woodwork, and a slate. When an invalid has need of a doctor, he engages him by attaching to this point his card, with name and address.

The Roman law is particularly protective to the "*pharmaciens*:" it assures them an honourable and lucrative position.

## Proceedings of Societies.

HARVEIAN SOCIETY OF LONDON.—APRIL.

DR. J. E. POLLOCK, President.

A PAPER was read by Dr. C. MEREDYTH on

"HYGIENE IN RELATION TO SYPHILIS."

The author began by observing that physiology and hygiene, pathology and therapeutics, ought not to be considered apart from one another, but as objective branches of a whole, namely, medical science, whose aim and end is the knowledge, in every aspect, of one subject. This subject is man. But the great truth must ever be present to the mind, that the facts which each branch establishes must all result from deductions springing out of the same axioms, arise from identical doctrines, and derive from the observation of analogous phenomena. Therapeutics stand in the same relation to pathology that hygiene does to physiology. Pathologists comprehend diseases in the most common generalities of their evolutions, which, strictly speaking, do not apply to any one in particular. Morbid

phenomena vary according to a multiplicity of individual circumstances. We ought, therefore, by deductions derived from the organic observation of the subjects, seek out the reason of all the phenomena, whether ordinary or unusual, and then adopt without hesitation the most judicious course of treatment. Now, pathologists rather suppose the methods are known than develop the rules how to apply them, in a word their doctrines are insufficient to guide the practitioner in the choice of the curative method to be adopted, according to the ever varying phenomena of disease, due, in most cases, to the different constitutions, temperaments, and idiosyncrasies of the patients. The differences which men offer between them are the specific traits of human individualities. Now the hygienist takes cognizance but of individualities, the general types of science are only products of reason, not beings of nature: hence the reason why hygiene, stable in its principles, varies in its application. The diversity of ideas, the conflict of opinions concerning the sense to be attached, and the influence to be conceded to the terms, constitution, temperament, idiosyncrasy, and inheritance, demands that their application to the subject under consideration should be defined. The unanimous concord of our predecessors on the fundamental idea of the essence of temperaments is sufficient evidence in favour of the doctrine which recognises their influence as modifiers of individual organisms. But the fate of all truths arising from observation is such that this influence has been interpreted in accordance with the dogmatic conceptions that have successively obtained ephemeral ascendancy. Borden emittit the idea that every subject has his predominant organ, and that by classing them we might perhaps discover what is so much sought concerning temperaments. Hallé developed this idea, and emitted sounder opinions on this branch of science than any of his predecessors. But to Bégín reverts the honour of having based the doctrine of temperaments on solid principles. The temperament is a "constitutional state, whose existence makes itself felt in all parts of the animal structure, because it depends on the preponderance of development and action of one of the three systems which penetrate all the tissues, animate and preside over their functions and nutrition: a state whose influence on the organism is general and immediate." The three systems on whose preponderance of development and action the constitutional state depends are the sanguine, the nervous, and the lymphatic. The whole economy, in a state either of health or disease, is impressed by them with an indelible character. An idiosyncrasy consists in the preponderance of an organ, a viscus, or even an apparatus, it expresses the particular effects of the nutritive or inciting fluids on this or that organ, and the consequent result arising from its relative superiority of development and activity. The principle of idiosyncrasies is but the connections of organs through mutual sympathies by reciprocal irradiations. Although there is much affinity between the temperament and the constitution, their characteristics and properties are radically distinct. The constitution is the general result of all the organic elements and individual differences: temperaments, idiosyncrasies, age, sex, inheritance, and habit. It expresses the general formula of the particular organisation of each individual, the sum of resistance to morbid causes, the proportion of vitality, and, consequently, the chances of longevity. Constitutions must be judged, like many other causes, by the sum of their result, which is *strength* or *weakness*. In short, the constitution compares individuals with the ideal standard of organic harmony, the *temperamentum temperatum* of the ancients; the temperament, the general systems that modify and give the form to individual nature; the idiosyncrasies, the organs with each other which, by their preponderance of activity and development, solicit the action of morbid causes. Inheritance rather implies a virtual disposition of the organism to realise, with the concurrence of occasional causes, the morbid affection, whose principal or virtuality has been communicated to it by the very act of fecundation, than the disease itself which affected the parents. We must not confound hereditary diseases with those contracted during intra-uterine life. Syphilis contracted during pregnancy, and transmitted to the fetus, either before or at the time of confinement, does not constitute a hereditary disease.

The lesions which compose the group of constitutional syphilitic eruptions spring from one source, the disseminating throughout the whole organism of a morbid principle, conventionally styled syphilitic virus. Chemical and micrographical researches have revealed nothing concerning its essence. All that can be affirmed is, that it is not a volatile, but a fixed principle. Its virulent character is disclosed but by its effects on the

organism. In regard to it, purulence is opposed to virulence; for, as soon as purulence sets in, the virulent intensity diminishes, and contagion frequently becomes impossible. The virus communicates its properties to the substances with which it comes in contact, and these substances, like the virus itself, exercise a specific action, but on condition that they shall have undergone no change. It even appears that the mortification of the tissues, which become the seat of this pathological secretion, destroys its noxious properties. The absorption of the virus is immediate; ablation of the chancre and cauterization at its earliest appearance, have not prevented infection. It does not germinate *in situ*, but is disseminated throughout the whole organism by the circulation. Hunter declared that "the venereal poison is capable of affecting the human body constitutionally, while diffused in the circulation;" yet, he did not believe that it was located in the blood, or "that the blood of a pocky person was capable of giving the disease to another, even by inoculation." This opinion is now untenable. The reverse has been peremptorily proved. Hence two hypotheses. First, the blood is virulent, because the economy impressed and modified by the contaminating corpuscle, is apt to secrete the virulent matter. This hypothesis requires that all the humours should be virulent, and such is not the case. Second, the blood is virulent, because the contagious principle is mixed with it, and has multiplied itself in it. This last hypothesis, although admitted by Astruc, accepted by Rollet, is in no way proved. However, if true, to which principle of the blood does the syphilitic virus more specially fix itself? The probabilities seem to be in favour of the globules, which carry along with them the syphilitic virus. Thus, it would appear that the tissues are modified by the sanguine globules, which must themselves have previously undergone some alteration. What is the nature of this alteration? The toxic hypothesis which has generally obtained, does not explain the regularity of the evolution of syphilis, progressing in order from the periphery to the centre. Hunter, the originator of the idea of intoxication, was fully alive to this fact; he therefore supposed that the parts were susceptible in consecutive degrees; but his explanation is vague and unsatisfactory, and in no way accounts for syphilitic affections becoming more serious the farther they are removed from the period of infection. This element of the question seems a most important subject of inquiry.

Littre and Robin define a virus "an organic substance of what humour soever having undergone, by isomeric catalysis, such a modification that, without the physico-chemical characters being notably changed, they have acquired the property to transmit the acquired modification to the organic substances with which they are put in contact." This mode of action of the syphilitic virus does not appear to have been refuted; yet, it is more satisfactory than any of the hypotheses that have enlisted the favour of syphilographers. Grassi's analysis of the blood of syphilitic subjects shows that the immediate action of the virus on the blood, is to destroy the globules and increase the albumen, the consequent result being an anæmia; but no research has been instituted in order to discover how this modification occurs. Now, the catalytic operation is all sufficient, not only to explain the deglobulisation of the blood, but the desintegration of all the tissues by the virus; for the blood, considered in a histological point of view, is a real tissue, which, as such, is subject to the action of a destructive principle, exactly as the other tissues are. However, that does not mean that the destruction of the globules is the cause of the destruction of the tissues; for it can be shown that there is no co-relation between the degree of alteration of the blood and that of the organs. But at the same time that the blood constitutes an organ, it serves as a vehicle; it is the globules of the blood which carry along with them the destructive element, and put it in contact with all the tissues. Now, the organs impregnated with this vitiated blood cease to act. Now, rest invariably involves denutrition; in other words, the organ condemned to inaction is not long in being transformed into a pathological substance. That is a first cause of retrograde metamorphosis. If, besides, the destructive element carried along by the blood offers exciting properties, the glands can become the seat of a granulous infiltration and even of a true inflammation. The noxious properties of the virus are only revealed to us by its first evident effect—the chancre; but in the interval between infection and the first manifestation, the virus has not been idle; on the contrary, the destruction of the globules is very great. Mr. A. Fournier draws our especial attention to the fact that the patients who served for Mr.

Grassi's experiments were in the early stage of the disease. He says—"I repeat, they only apply, and can only apply, to the first stage of syphilis.—Beyond . . . analysis demonstrates that the blood recovers its normal composition." The process of contamination is at first slow and consecutive. The virus fixes itself on some of the globules, and, *without undergoing any change*, exercises upon them a molecular disintegrating power; these globules come in contact with others, which, in their turn, take up the virus, and also become agents of contamination; and as these go on multiplying, the molecular disintegration proceeds in a mathematical progression. The effect of the action of the virus is at first imperceptible, but as the molecular disintegration progresses, the whole economy becomes impressed and suffers in the very essence of its vitality, the nutritive fluid. The organism now reacts, and, assisted by nature's powers, strives by all the means at its disposal to thrust out the destructive element. All the channels of elimination are brought into requisition and taxed to their utmost powers. Up to this period of the disease, all the accidents which furnish a product of secretion are contagious and inoculable. After more or less time the virulent agent is eliminated; it can no longer be found in the blood, nor in any of the products of physiological or pathological secretion. The disease, however, has not exhausted itself, the cause only has been checked; the organism still suffers, and has to struggle to repair the damage it has sustained. This is the truly chronic period of the disease, to the impression of the virus has succeeded a general disintegration of the tissues on which it had exercised its destructive property, from which has resulted a profound modification of the organism; in fact, the animal machine has sustained a great shock and undergone a kind of degeneration. The catalytic operation of the virus once admitted, the influence of individual differences becomes evident. By the constitution, we shall find the sum of resistance to the morbid principle of the disease, and the power of reparation of its baneful action. The temperament will furnish us with the form of the eruption, as can be shown by the analysis of 1800 cases, in which the constitutions, temperaments, &c., of the patients had been studied by the scrupulous Mr. Devergie.

The foregoing considerations lead to the conclusions:—

1stly. That the syphilitic virus is immediately absorbed on infection.

2ndly. That its first action on the organism is the molecular disintegration of the globules of the blood by catalysis, from which results an anæmia in the early stages, and a cachexia in the last stages, caused by the exhaustion of the animal machine, arising from the sustained efforts of an enfeebled organism to eliminate a destructive element in the tissues and repair their disorganization.

3rdly. That syphilitic lesions consist in a molecular disintegration of the tissues.

4thly. That on the relative strength or weakness of the constitution depends the intensity of the accidents of the disease; on the temperament the form; on the idiosyncrasies the particular direction of the virus.

5thly. That syphilis can only be cured by the elimination of the virus by nature's powers; but that it is the province and within the scope of art to aid and promote her salutary efforts.

Lastly. That all so-called specifics are incapable to modify, counteract, or destroy the specific properties of the virus, but are all-powerful when directed against the accidents due to its special action on the tissues.

Dr. BALLARD remarked that he had never seen a case of infantile syphilis, although he had often heard of such cases. They must, he believed, be very rare.

Mr. DE MERIC had expected that the author would have read the argument that, as syphilis was a disease which enfeebled, we should therefore use it by analeptic and other hygienic applications. This argument was spurious: but erroneous, because syphilis was not strictly analogous to other exanthemata.

Dr. DRYSDALE was glad to learn the value of restorative means spoken of in cases of syphilis, instead of the continual assertion that syphilis alone of all the blood-poisons was to be treated empirically, and by means of so capricious a drug as mercury. Fortunately, as Dr. Ballard had said, hereditary syphilis was rare, in proportion to the vast number of parents who had been sufferers from syphilis.

Dr. COCK thought that syphilis, and all the exanthemata, would sooner or later be found to be diseases produced by the attacks of certain animalculæ, and that this was the way in which their action could be best understood.

## PATHOLOGICAL SOCIETY OF LONDON.

At the meeting on the 16th ult., the following rules were adopted for the Committee on morbid growths:—

1. The name of the Committee to be "Committee on Morbid Growths and Deposits."

2. The object of the Committee is particularly to ascertain if any and what relation exists between anatomical structure and those clinical characters ordinarily regarded as "malignant."

3. The specimens to be submitted to this Committee are to be such as the President may deem proper. With regard to specimens so referred, the following regulations must be complied with:—

1. The specimen must be either fresh, or in a jar or bottle with some preservative fluid.

2. The specimen must be accompanied by a written description and clinical history.

3. The specimen must be placed at the disposal of the Committee at the close of the meeting, for examination.

4. Where the above regulations have not been complied with, the specimens will not be reported upon by the Committee; nor will the case be published in the *Transactions*, without the express sanction of the Council.

5. In the case of specimens taken from persons still living, it will be understood that the exhibitor undertakes, as far as possible, to inform the Society of the progress of the case, for publication in the *Transactions*.

6. The notes and descriptions of the specimens referred to the Committee, with the Committee's description of early specimens, will form "the Annual report of the Committee on Morbid Growths and Deposits," which will constitute a section in each volume of the Society's *Transactions*.

7. It will be desirable that the Committee shall have in view the object of ultimately preparing a general report on the matters of their investigation.

8. The composition of the Committee shall be determined from time to time by the Council, and shall be reconsidered at the commencement of each session.

## SURGICAL SOCIETY OF IRELAND.

APRIL 26, 1867.

The PRESIDENT of the Royal College of Surgeons in the Chair.

Dr. WHARTON read the following

CASE OF NECROSIS OF THE TIBIA, IN WHICH THE CENTRAL PORTION OF THE SHAFT WAS REMOVED BY OPERATION,

Which was inadvertently omitted from the reports of the Society of that date.

Dr. WHARTON said—The following account of a case of necrosis of the tibia, which I shall very briefly detail, is, I think, not altogether unworthy of the notice of the members of this learned Society. It affords an illustration of the benefits which accrued from timely assistance, by means of operative proceedings of a trivial kind, and is an evidence of the value of patience in the management of chronic surgical affections of bony structures, in which, from the nature of their organisation, repair must necessarily be slow. James Faulkner, aged 33, a pensioner, who had served some years in India, was admitted to the Meath Hospital under my care for the first time, in August 1863. He was then complaining of an ulcer, situate in the front and centre of the right tibia. This ulcer did not present any remarkable characters. It had existed, however, for a period of three months, and, according to Home's classification, now all but obsolete, might be regarded as an example of that variety dependent upon a deficiency of strength, both in the party concerned and in the constitution, to bring about a healthy action. Its size was small, about that of a halfpenny. In tracing its history, I learned that however trifling in itself it might appear, yet, in reality, it possessed considerable importance. It was not so much an affection in itself, as an evidence and result of pre-existing disease of the periosteum of the tibia. The patient had never received any direct injury, but it would appear that in June, 1858, five years previously, while on the march to Benares, he felt as if his "ankle-joint got a jerk, and turned under him." He continued his march, although he suffered much pain, and on arrival at his destination he mounted guard in his turn, and attended to the usual duties of a soldier. Subsequently he marched to other quarters, and remained till

November, 1859, a period of eighteen months, without reporting himself as unfit for duty, notwithstanding that he became the subject of increasing pain from aggravated attacks of inflammation of his leg. It may be well to remark that although the patient was of a delicate aspect, yet he had never been previously out of health, and never had syphilis. His habits were strictly temperate. After a stay of five weeks in hospital, the ulcer was healed chiefly by means directed to improve the general health, which was much below par. In January, 1865, he fell under my care for the second time, not on account of the breaking out of the original sore, but in consequence of an ulcerated condition of the integuments on the upper and anterior portion of the tibia. This was accompanied with a very considerable discharge of pus. Upon examination, it was found that direct communications existed between the openings on the surface, and the subjacent cancellous tissue of the bone, and upon closer observation it was found that a portion of this structure was being separated. After the lapse of a few days—having enlarged, so as to connect the openings, I was enabled to remove the cause of so much distress. According to the account of the patient, who is a very intelligent man, this affection had originated in the November previously. It commenced suddenly, with but slight pain, to relieve which he made use of warm poultices, and in two days "an abscess broke through a pin-hole opening," which gave exit to pus having "a fetid odour." It was now evident, from an inspection of the leg, that necrosis of the shaft of the tibia, was sure to follow, if, indeed, it had not already commenced. The periosteum was raised; sub-periosteal effusion had taken place; the skin and adjacent soft parts were dusky, thickened, and infiltrated; pain in the bone itself was complained of, and manifested on pressure. To relieve this condition, it was deemed advisable to incise the periosteum to the extent of between two and three inches. This was followed by immediate, but only temporary, relief. Free exit, however, was given to the discharge of the inflammatory products. Abscesses followed; which, when healed, were liable to re-open, or to be succeeded by others in their neighbourhood. As the patient's health had seriously declined, he was advised to leave hospital for a while in order to recruit his health. In July of the same year he was again—for the third time—admitted to hospital, much shattered in health, and not a little depressed at the near approach of the expiration of the period for which he had been granted a pension. This latter difficulty was happily removed, chiefly through the influence of Deputy Inspector-General O'Flaherty, whom I take this public opportunity of thanking for his kind services. The patient's condition, at this juncture, was one of much anxiety to myself, and of danger to him. A considerable portion of the shaft of the tibia was palpably necrosed. Severe pain, and a wasting discharge, from many openings, rendered it necessary that prompt and decided measures should be adopted with the view of averting a fatal termination, which appeared to be slowly but surely advancing. With the consent of my colleagues, I proposed to remove the diseased portion of the tibia—the question of amputation of the limb, which seemed almost inevitable, having been postponed and reserved in case of the failure of the proposal submitted to him. To this the patient eagerly consented. Accordingly, as soon as a sufficient improvement had taken place in his general condition, as effected by generous diet and other means, I proceeded to lay open the different sinuses which permeated the soft parts, and this done, I selected a favourable situation for the application of the trephine. Having, by this means, removed a portion of bone, the subsequent steps were carried out by means of elevators, cutting, and other forceps. The operation was submitted to, as became a soldier, chloroform not having been used. The cavity left in his leg almost amazed me. I could easily introduce my four fingers into, what I might call, the excavation, which had been made. The entire of the dead bone was not, however, removed, some portions of which could not be reached, and others probably being, as it were, locked. During his stay in hospital the patient was enabled, by means of an ordinary dressing forceps, to extract several small pieces as they became loosened. Improvement by degrees became evident, sleep and appetite returned, fever abated; emaciation, which had taken place, was stayed, and the bottom of the wound became visible from the granulation which had commenced. In six weeks he was enabled to return home, where the strength of the limb became so much increased that unfortunately, in the act of attempting to lean, what proved to be too much weight upon it, he fractured his fibula. For the fourth time he was received into hospital,

suitable apparatus was made use of, and in due time the fracture was united. He was now sent to the sea-side for a month with much advantage to his general health, although it was more than probable that there still remained portions of dead bone to be removed, as occasional abscesses appeared, and the original openings had not closed. After a fifth admission to hospital, where he remained for several weeks, a second visit to the country, and for the like period, was arranged for him. After which he was for the sixth time admitted to hospital, in consequence of considerable inflammation having sprung up afresh, followed by a renewal of abscesses, arrest of the granulation which had been developed, and the establishment of severe constitutional disturbance. Hopes of saving the limb became now slender indeed. However, after a prolonged stay in hospital, the source of all this mischief, another, and I hope the last portion of dead bone, was at last reached and removed. Progress, which would appear to be permanent, has since October, 1866, been steadily manifesting itself. Pain and discharge have entirely ceased. The general health is re-established. The limb, though necessarily much deformed, is strong. The patient, with the aid of a stick, takes daily exercise on foot. The cast of the limb which I exhibit does not exactly display the amount of deformity, as it was taken from below the knee, the prominence of which renders the loss of the shaft more marked. The portions of necrosed bone removed, are on the table for your inspection. The patient is in the hall, and ready for the examination of the members of the society, if they so desire. I am sorry that, according to the present regulations of the Society, he cannot be allowed to walk into the Society, and exhibit his limb. I have purposely refrained from entering into any details as to the local or general treatment of the case. Such a course is unnecessary, and if entered upon would unwarrantably intrude upon the patience and time of the society.

## Correspondence.

### THE SUCCESSOR TO SNOW.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have the honour to enclose for your perusal a letter I have lately received from a Dr. Charles Kidd, with reference to certain remarks made by me in a paper, which I read before the Harveian Society of London, and an abstract of which, forwarded by the honorary secretary, you were kind enough to publish, April 24th, 1867. I also send my answer to the same.

While writing, may I correct a slight mistake in the published report. I said or meant to say that "I had on no occasion required to use more than two fluid ounces of chlorætherine in any one case," whereas, in my published answer, I am reported as saying that I had never used more than one fluid ounce.—Your obedient servant,

ISAAC BROWN.

[COPY.]

25, Sackville-street, W., May 1st.

Dr. Kidd's compliments to Mr. Brown junior. His attention was drawn only to-day to a paper in the MEDICAL PRESS AND CIRCULAR, about chlorætherine, where it appears that, according to Mr. Brown, who was in Anstralia, Dr. Sansom has been giving most time and attention to chloroform, &c. Mr. Brown does not know that Dr. Kidd has been exactly twenty years writing about chloroform. Dr. Sansom was a first year's student when Dr. Kidd had stated things that now figure in S's. book copied from Dr. Kidd. Sansom has been three or four years compiling other men's ideas. Dr. Kidd worked with Dr. Snow, and has been twenty years!

Dr. Kidd has complained to Mr. Brown's father about this, and his stating that his father had most confidence in Sansom, which his father says is simply untrue and absurd.

The best thing Mr. Brown could now do would be to go to Renshaw's and buy Dr. Kidd's book, and see for himself; but certainly it is most unfair for him to be going about to Societies talking what is not correct. Dr. Kidd was sent exactly twenty years ago by the *Medical Times* to report on chloroform in Paris, when Sansom was a baby at school! It is most unfair, under the shadow of the "Surgical Home," to be stating what is not exact.

Dr. Kidd has had independence enough to stick by the "Home," in spite of all the recent clap-traps. The re-action now in all the hospitals in favour of Mr. Brown's father shows that Dr. K. was right. He went to present the testimonial too,

and second Mr. Propert, rather than join the numerous people that have been making such a row!

Mr. Isaac Brown.

[ANSWER.]

14 Cambridge-street, Hyde Park, W.

May 3rd, 1867.
